Taxonomy Originally described in the genus *Tatera* (see genus profile). The definition of this species is uncertain. Musser & Carleton (1993) limit *Tatera valida* (now *Gerbilliscus validus*) to eastern and central Africa; in contrast, Bates (1988) considered *kempi* to be a synonym of *validus* and hence extended the distribution of *validus* to the western edge of West Africa. Here, following Musser & Carleton (1993, 2005), *kempi* and *validus* are considered to be separate species. The status of populations in the central part of the northern savannas, where the two species meet, is uncertain because few specimens are available. This species is closely related to *G. robustus*, and the two taxa may, in fact, represent a single polymorphic species (D. Kock pers. comm.). Chromosome numbers vary in different regions of the *validus*–*kempi* geographic range, and it is uncertain whether these represent chromosome polymorphism in a single species or are indicative of separate species. Synonyms: *liodon*, *neavei*, *taborae*. Subspecies: possibly two. Chromosome number: not known.

Description Large dark gerbil with relatively short tail. Dorsal pelage dark brown; hairs dark grey, with buff or black tip. Flanks paler; hairs grey with buff or brown tip. Ventral pelage pure white. Dorsal and ventral colours clearly delineated. Fore- and hindlimbs white or buffy-white. Soles of hindfeet deeply pigmented and naked. Digits with long pointed claws. Tail of moderate length (ca. 95% of HB), thickly covered with short hairs, brown above, pale below; without black hairs and without terminal pencil (cf. other *Gerbilliscus* spp.). Skull: rostrum short and broad; width of M^1 : 2.5 (2.2–2.8) mm (cf. *G. robustus*; see Table 23). Males often slightly larger than ♀♀. Nipples: 1 + 2 = 6, 2 + 2 = 8.

Geographic Variation Many variations have been reported (originally as species, now considered synonyms). Individuals from northern semi-arid regions (e.g. Sudan) are paler than those from mesic areas (e.g. near L. Victoria). Bates (1988) refers to two subspecies (southern: *kempi*; northern: *valida*), based on the shape of the anterior lamina of the first lower molar tooth.

Similar Species

G. robustus. Tail ca. 115% of HB, often black on upper terminal half of tail, paler below, some individuals may have almost all-black tails; width of M^1 2.0–2.4 mm.

G. nigricaudus. GLS longer; tail ca. 100% of HB, always black above and below; width of M^1 2.4–2.5 mm.

G. phillipsi. GLS on average smaller; tail ca. 130% of HB, orange-brown above; width of M^1 <2.1 mm.

Distribution Endemic to Africa. Zambezi Woodland BZ, and northwards to eastern parts of Guinea Savanna and Sudan Savanna BZs. Recorded from Angola, S and E DR Congo, Zambia, Tanzania, Uganda, Sudan and W Ethiopia. The western limit in the savanna zones north of Rainforest BZ is uncertain (see above). Musser & Carleton (2005) do not include Sudan in the distribution of this species, preferring to allocate the Sudanese populations (and those to the west) to *G. kempi*.

Habitat In Tanzania, prefers well-drained sandy soils on the edges of valley grasslands above the flood-plain. Also found in sandy alluvium along rivers, and in abandoned cultivations (Vesey-Fitzgerald 1966). Recorded from upland grassland savannas in DR Congo. In Ethiopia, found only in the dry river valleys and gorges, not on the plateaux.

Abundance Recorded as ‘particularly abundant’ along the edge of flood-plain grasslands in the Rukwa Valley ‘where honey-combed warrens may extend for many miles along a belt facing the tree line’ (Vesey-Fitzgerald 1966). No information from elsewhere.

Adaptations Nocturnal and terrestrial. Like *G. robustus*, these gerbils dig complex burrow systems with multiple entrances. Burrows are 45–60 cm deep, with a chamber, and a steeply ascending

escape passage. A burrow system may cover an area of about 2.4×1.4 m. Often there are many burrows close together forming a warren. Runways on the surface lead from one burrow to another, and sometimes between warrens. During the day, gerbils shelter in the burrows. During the dry season, they can exist without access to free water. Sedentary, rarely leaving the safety of the warrens (Vesey-Fitzgerald 1966, Delany 1975).

Foraging and Food Omnivorous and herbivorous. In Tanzania (Vesey-Fitzgerald 1966, as *Tatera valida*), underground parts of grasses and sedges are the principal food. Feeding activity in the soil under the warrens kills the herbaceous vegetation so the soil on the surface becomes completely bare. Also feeds on blades of green grass in the wet season. One stomach of an individual in Uganda was full of insect remains (Delany 1964a).

Social and Reproductive Behaviour Lives in small groups.

Reproduction and Population Structure In Queen Elizabeth N. P., Uganda, two periods of reproduction each year during the wet seasons (mostly May–Jul and Sep–Dec) (Neal 1982). Embryo number: 3 ($n = 1$), 4 ($n = 4$) (Delany & Neal 1969, Delany 1975). Sexual maturity when 90–100 g. Reproductive capacity appears to be low: the interval between litters recorded as 109 days, and hence production of young is only 8.5 young/female/year (Neal 1982). The structure of the population (based on HB length) shows that there are adults and subadults during most months of the year, with young animals predominating in Jun–Aug and Dec–Feb.

Predators, Parasites and Diseases Preyed on by Servals *Felis serval*, Wild Cats *Felis libyca*, Puff Adders and House Snakes (Tanzania; Vesey-Fitzgerald 1966).

Conservation IUCN Category: Least Concern.

Measurements

Gerbilliscus validus

HB: 167 (135–195) mm, $n = 57$

T: 157.2 (115–186) mm, $n = 58$

HF: 34.0 (30–39) mm, $n = 58$

E: 21.8 (17–29) mm, $n = 57$

WT: 129 (90–160) g, $n = ?$

GLS: 41.7 (38.5–44.7) mm, $n = 65$

GWS: 21.1 (19.1–22.2) mm, $n = 47$

M^1 – M^3 : 7.1 (6.1–7.8) mm, $n = 70$

Auditory bulla: 12.9 (11.5–13.8) mm, $n = 68$

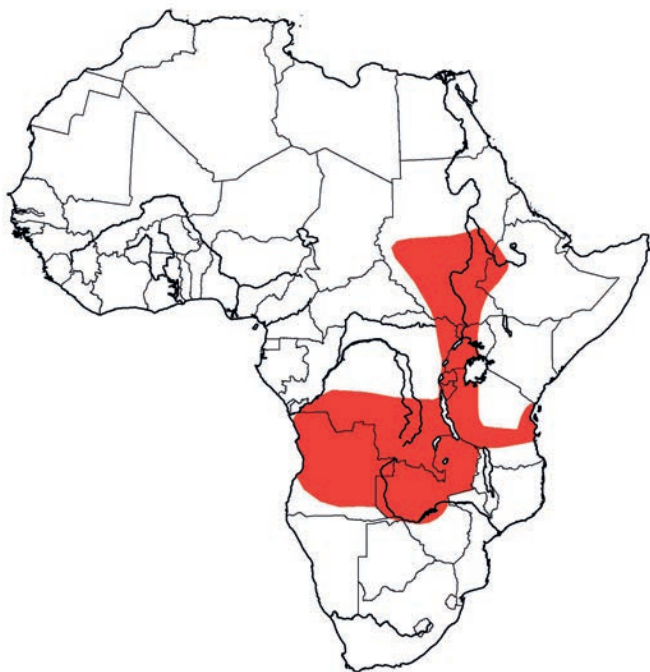

Measurements: throughout geographic range (Bates 1988, as *Tatera valida*)

Weight: Uganda (Neal 1982, as *Tatera valida*)

Males only; mean measurements for ♀♀ are slightly smaller than for ♂♂

Gerbilliscus validus

GENUS *Gerbillurus*

Hairy-footed Gerbils

Gerbillurus Shortridge, 1942. Ann. S. Afr. Mus. 36 (1): 52. Type species: *Gerbillus vallinus* Thomas, 1918.

Gerbillurus vallinus.

The genus contains four species, which are restricted to the South-West Arid BZ and live in desert or semi-desert regions. The genus is characterized by small body size, long tail with variable terminal pencil, partially furred soles of the elongated hindfeet, large eyes and long rounded ears. Dorsal pelage varies from pale blonde to dark reddish-brown, with considerable geographic variation. Ventral pelage is always white (as in *Gerbillus*). The skull has inflated auditory bullae; molar teeth lack longitudinal crests connecting tooth cusps (cf. *Gerbillus*) (Figure 49).

The genus is the ecological equivalent of the genus *Gerbillus* of the arid regions of North Africa. *Gerbillurus* species move by quadrupedal saltation, and are capable of leaping up to four times their body length in a single hop. All species in the genus live in arid or semi-arid regions with scant vegetation. They dig their own simple burrows in sand or gravel, and each burrow contains a nest of shredded vegetation. Their diet varies according to the season; although mainly herbivorous, they eat seeds and insects at some times of the year. All species have good water-conserving abilities – concentrated urine, low faecal water loss and low water turnover. They avoid extreme daytime temperatures by remaining in their burrows where temperature and humidity are stable, and

Figure 49. Skull and mandible of *Gerbillurus vallinus* (BMNH 25.1.2.85).

restricting activity to cooler nights. Sporadic population explosions have been reported in some species.

Gerbillurus was originally described as a subgenus of *Gerbillus*, but raised to generic rank by Shortridge (1942), a determination followed by Davis (1975a) and Musser & Carleton (1993, 2005). Molar enamel patterns indicate a closer relationship with *Gerbilliscus* (formerly *Tatera*) than with other gerbil groups. Chromosomal data support the close relationship between *Gerbillurus* and *Gerbilliscus*, with *Desmodillus* more distantly related (Qumsiyeh *et al.* 1991).

The genus *Gerbillurus* may be divided into three subgenera: *Progerbillurus* (containing only *G. paeba*) characterized by small HB (mean 96.5 mm), small skull length (mean 28.6 mm) and small mean auditory bullae length (<9 mm); *Paratatera* (containing only *G. tytonis*) characterized by moderate HB (mean 99 mm), moderate skull length (mean 99 mm) and auditory bullae 9.3–10.1 mm; and *Gerbillurus* (*G. setzeri*, *G. vallisus*) characterized by the largest HB (means 101, 105 mm), largest skull length (29.9, 31.4 mm) and the longest auditory bullae (10.6–12.4 mm). These subgenera roughly correspond to the ‘*paeba* group’ (*G. paeba* only) and the ‘*vallisus* group’ (the other three species) of Schlitter (1973). Chromosomal data and habitat selection suggest that *G. paeba* and *G. tytonis* (both $2n = 36$,

$FN = 68$, preferring areas of loose sand) are closely related, while *G. setzeri* ($2n = 60$, $FN = 76$) and *G. vallisus* ($2n = 60$, $FN = 80$) form a second phylogenetic group, which are associated with gravel plains (Qumsiyeh *et al.* 1991).

The species may be distinguished on body size, relative length and form of tail, length of auditory bullae, length of posterior palatine foramina and chromosome number (Table 24). They are also distinguished by habitat, with *G. paeba* being far more widespread than the three specialist species.

Edith R. Dempster

Gerbillurus paeba PYGMY HAIRY-FOOTED GERBIL (PAEBA HAIRY-FOOTED GERBIL)

Fr. Gerbille pygmée à pieds velus; Ger. Paeba Zwergrennmaus

Gerbillurus paeba (A. Smith, 1836). Rept. Exped. Exploring Central Africa, app. p. 43.
‘Country beyond “Latakoo”; Vryburg, Northwest Province, South Africa’ (Roberts 1951).

Taxonomy Originally described in the genus *Gerbillus*. *Gerbillurus paeba* is the most widespread, generalized and primitive species of the genus, in contrast to the specialized desert species. Now assigned to *Gerbillurus*, subgenus *Progerbillurus* (see profile Genus *Gerbillurus*). Karyotypically similar to *G. tytonis*. Synonyms: *broomi*, *calidus*, *coombsi*, *exilis*, *infernus*, *kalaharicus*, *leucanthus*, *mulleri*, *oralis*, *swakopensis*, *swalius*, *tenuis*. Subspecies: five. Chromosome number: $2n = 36$, $FN = 68$ (Schlitter *et al.* 1984; Qumsiyeh 1986). Karyotypically similar to *G. tytonis*.

Description Small hairy-footed gerbil with white underparts, darker dorsal surface and long slightly tufted tail; the smallest species of the genus. Dorsal pelage varies with locality (see below) from reddish-orange to greyish-red or pale cinnamon-buff, with admixture of dark hairs. Colour of dorsal pelage matches colour of substrate. Ventral pelage pure white from chin to tail tip, extending to fore- and hindfeet and well up on to flanks. Head narrow, with pointed nose. Sides of muzzle white. Large deep reddish-brown eyes; small white supraorbital patch, not always discernible. Ears long and rounded, sparsely haired, paler colour than dorsal pelage, with darker margin. Hindlimbs much longer than forelimbs. Forefeet and hindfeet pure white, five digits each, fairly long claws; Digit 5 on forefeet reduced. Hindfeet elongated, soles of hindfeet furred except for a naked central line. Tail long (ca. 120% of HB), same colour as dorsal pelage above, white below; slightly tufted at tip. Skull: posterior palatal foramina >1.6 mm, auditory bullae slightly inflated posteriorly and laterally (8.91 [8.08–9.24] mm) but not extending posteriorly beyond occiput (cf. other spp. of genus). Nipples: $1 + 2 = 6$.

Geographic Variation

G. p. exilis: Alexandria dune field, Eastern Cape Province, South Africa. Larger than *G. p. paeba*; colour of dorsal pelage pale cinnamon-buff.

G. p. paeba: widely distributed throughout arid areas from SW Angola to Western Cape and Eastern Cape Provinces, South Africa. Size as described above; colour of dorsal pelage pale reddish-orange, but considerable variation.

Gerbillurus paeba

G. p. infernus: Skeleton Coast, Namibia.

G. p. coombsi: Soutpansberg, Limpopo Province, South Africa. Smaller than *G. p. paeba*.

G. p. mulleri: Cape Flats, Western Cape Province, South Africa. Larger than *G. p. paeba*, colour of dorsal pelage distinctive grey.

Similar Species

G. tytonis. Darker colour, larger size, longer hindfeet with splayed toes and distinctive fringe on digits, longer tail.

G. setzeri. Paler colour, larger size, distinct pencil at tip of tail.

G. vallisus. Darker colour, larger size, longer tail.

Distribution Endemic to Africa. South-West Arid and South-West Cape BZs. Recorded in SW Angola, Namibia, Botswana, W

Zimbabwe, W Mozambique and South Africa (Northern, Western and Eastern Cape Provinces). Substrate and vegetative cover are important habitat factors determining distribution. Isolated populations occur in the Alexandria dunefield of Eastern Cape Province, and relict patches of Kalahari sand in Limpopo Province, South Africa.

Habitat Arid or semi-arid environments with sandy soil or sandy alluvium, and with scant cover from grass, scrub, or occasionally light woodland. Absent from rocky areas and deep sand dunes of the Namib Desert (Griffin 1990) and consolidated soils in NE Botswana. Common in the Kalahari Desert in lightly vegetated dune slopes, calcrete river banks and pans with fine soil. Avoids areas of high plant diversity, and prefer more compact soil in inter-dune valleys than areas of deep sand in the eastern Namib Desert (Perrin *et al.* 1999a). *G. p. coombi* is restricted to sandy areas in Soutpansberg area of Limpopo (Rautenbach 1978), and *G. p. exilis* prefers dune valleys to dune crests in a coastal dunefield at Alexandria, Eastern Cape (Ascaray 1986).

Abundance Common throughout distribution range, and subject to massive fluctuations in population numbers. The most abundant rodent species in the Kalahari Desert, comprising 90% of the total rodent community in sand dune habitat and 54% in river bed habitat (Nel 1983). In the pro-Namib, density increases from near zero to 59/ha following good rains, and after experimental water provisioning and burning (Christian 1979a). Density of *G. p. paeba* varied from 1.0 to 7.7/ha in the eastern Namib Desert during 1984–85 (Perrin & Boyer 2000), while population density of *G. p. exilis* in Alexandria dunefields ranged from 0.7 to 3.3/ha (Ascaray *et al.* 1991).

Adaptations Terrestrial and nocturnal. Moves by quadrupedal saltation, and may leap up to 26 cm in one hop. Sandbathes frequently to maintain coat condition. *Gerbillurus p. paeba* in the Namib Desert excavate simple, unbranched burrows, with a single entrance leading to a blind-ending tube. Some burrows contain a wider nest area off the main tunnel. *Gerbillurus p. exilis* constructs complex, branched burrows, with entrance hidden in vegetation, never plugged with sand. Nests are cup-shaped, and constructed of shredded vegetation. Food caches containing seeds, leaves and insects are found in some tunnels. Burrow temperatures in Namib are stable at 22.9–24.4 °C at surface temperatures of 15.8–28.4 °C. Burrow humidity varies with weather conditions, being highest early morning and during fog or cloudy weather.

Avoids extreme aridity and temperature by nocturnal activity and fossorial habits rather than physiological adaptations. Preferred ambient temperature in laboratory trials (ca. 28 °C) slightly higher than mean burrow temperature in field. Body temperature is maintained at ca. 36–39 °C over range of ambient temperatures of 5–30 °C. Animals cannot survive ambient temperatures above 35 °C for more than one hour.

Energy is conserved by having a lower basal metabolic rate at thermoneutrality (32.3–35.1 °C) and slightly lower thermal conductance than expected for its body mass. Behavioural avoidance of high temperatures reduces the need for costly evaporative cooling mechanisms, thus conserving energy and water.

Renal function is efficient, but a diet of insects or succulent plant material is required to maintain water balance. Field water turnover

rate varies with environment from 85 ml/kg/day in the central Namib Desert to 232 ml/kg/day on the Namibian coast, both measurements taken in summer (Mar). Water turnover rate and urine osmolarity in captive animals varies with protein content and potential water yield of the diet. When deprived of water, a precipitate of allantoin contributes to reducing overall water output (Perrin *et al.* 1999a).

Foraging and Food Omnivorous and opportunistic; diet varies according to availability of suitable food. Principal foods of *G. p. exilis* are seeds of littoral marine plants, although arthropods are preferred in summer. The diet of *G. p. paeba* in the Karoo is, on average, 36.2% seeds, 46.8% foliage and 17.1% insects, with more seeds consumed in summer and autumn, more foliage in winter and more insects in spring (Kerley 1989). In the Kalahari, the diet of *G. p. paeba* was 76.4% white plant material, 23.6% green plant material and 0% insects in winter, changing to 39.3%, 43.8% and 16.8%, respectively, in summer (analysis of stomach contents; Nel 1978). In the E Namib Desert, *G. p. paeba* is mainly insectivorous and has little seasonal variation in diet (3.8% seeds, 40.6% green plant material, 52.9% arthropods and 3.0% unidentified material). Plant growth and production are affected by the foraging activities of *G. p. paeba* on the inter-dune plains of the eastern Namib, but impact is local and transient. Removal of green parts of plants may adversely affect plant growth, and seed predation may adversely affect plant species diversity (Perrin *et al.* 1992).

Social and Reproductive Behaviour *Gerbillurus p. paeba* is very active and aggressive in laboratory encounters. Simple burrow structures, and scattered nature of burrows, supports the view that *G. paeba* is solitary and intolerant of conspecifics. In staged laboratory encounters, *G. p. exilis* is less aggressive and active than *G. p. paeba*, with ♂♂ frequently seeking contact with conspecifics. Aggressive behaviour is expressed in the form of chasing, with occasional bouts of mutual 'boxing' rather than biting and kicking. May be displaced by *G. tytonis*, a more aggressive species, from favoured habitats where the two species are sympatric in the E Namib Desert.

Two of the subspecies, *G. p. paeba* and *G. p. exilis*, show no significant preference for odours of their own subspecies, and do not discriminate between potential mates of their own and a different subspecies in staged encounters. Acoustic communication occurs through footdrumming with the hindfeet, and ultrasonic whistles. In *G. p. paeba* and *G. p. exilis* ultrasonic whistles consist of strongly modulated whistles lasting about 78 msec, and broadband clicks with a duration of 21–22 msec. Main frequency range of whistles is 57–70 kHz, for *G. p. paeba* is 57–70 kHz, and 46–57 kHz for *G. p. exilis* (Perrin *et al.* 1999a).

Reproduction and Population Structure In Botswana, pregnant ♀♀ were recorded in all months of the year except Apr, May, Sep and Nov (sample sizes 7–61/month; n = 304 ♀♀); pregnancy rate in the months when pregnant ♀♀ were recorded was 8% to 28% (Smithers 1971). In E Namib Desert, reproductive activity was confined to mid- to late summer (Dec–Apr). Juvenile recruitment occurs during autumn and early winter (Feb–Jun) (Perrin & Boyer 2000). Increased population density follows summer rainfall in the Namib Desert (Christian 1979a, b), Kalahari Desert (Nel 1978) and in the Karoo (Kerley 1990).

Increased photoperiod stimulates reproduction in captivity. Oestrus cycle of *G. p. paeba* lasts 6–7 days, while that of *G. p. exilis* lasts 7–8 days in captivity. Litter-size: 3.7 (2–5, $n = 39$; wild-caught ♀♀, Botswana; Smithers 1971); 4.6 (1–6, $n = 7$; captive ♀♀; Perrin *et al.* 1999a); 3.7 (2–6, $n = 10$; *G. p. exilis*; captive ♀♀; Ascaray 1986). Gestation (*G. p. exilis*): 21 days. Females give birth in underground nests, and rarely leave the neonates during the first few days of life. Young altricial at birth; mean weight at birth 1.9 g ($n = 23$). Growth rate in first 21 days: 0.4 g/day. Incisors erupt at Day 12. Eyes open at Day 14–18. Weaning from Day 21 (Ascaray 1986, Perrin *et al.* 1999a). Young do not nipple-cling.

Predators, Parasites and Diseases Major predators in pro-Namib Desert and Alexandria dunefields are Spotted Eagle-owls *Bubo africanus* and Black-backed Jackals *Canis mesomelas*. Also taken by Large-spotted Genets *Genetta tigrina* in the Alexandria dunefields. Host to 11 species of fleas, two species of mites and one species of tick (details in De Graaff 1981), including some of economic importance.

Conservation IUCN Category: Least Concern.

Measurements

Gerbillurus paeba

Gerbillurus setzeri SETZER'S HAIRY-FOOTED GERBIL

Fr. Gerbille pygmée de Setzer; Ger. Setzers Zwergrennmaus

Gerbillurus setzeri (Schlitter, 1973). Bull. S. California Acad. Sci. 72: 13. One mile east of the Namib Desert Research Station, Gobabeb, Namibia.

Taxonomy Originally described in the genus *Gerbillus* (subgenus *Gerbillurus*). Together with *G. vallinus*, assigned to the subgenus *Gerbillurus* (see profile Genus *Gerbillurus*). Synonyms: none. Chromosome number: $2n = 60$, FN = 76 (Schlitter *et al.* 1984, Qumsiyeh *et al.* 1991) Karyotypically similar to *G. vallinus*.

Description Small, robust pale-coloured gerbil, the largest of the species of *Gerbillurus*. Dorsal pelage pale sandy-brown (never reddish or rusty coloured); hairs pale slate-grey on basal half, pale sandy on terminal half. Flanks paler. Ventral pelage pure white. Colour of ventral pelage clearly delineated from dorsal pelage. Cheeks, chin and throat white. Large eyes with supraorbital white patch, which may be indistinct. Ears pale, unpigmented, sparsely covered with hairs that are same colour as on dorsum. Well-developed black and white vibrissae. Fore- and hindlimbs white. Forelimb with five digits; Digits 2–5 with claws, Digit 1 reduced without claw. Hindlimbs with five digits, each with claw and dense white hairs on undersurface of digit. Soles of hindfeet pale and hairy. Tail long (ca. 120% of HB), same colour as dorsal pelage above, white below, with well-developed grey pencil on distal one-third. Skull: auditory bullae inflated posteriorly and laterally (oblique length 10.6–12.4 mm (Schlitter 1973) extending posteriorly to occiput. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

G. paeba. Similar colour where sympatric; on average smaller; tail without distinct pencil; $2n = 36$.

G. tytonis. Darker colour; on average smaller; slightly longer tail relative to body size; no distinct pencil, $2n = 36$.

G. vallinus. Darker colour; on average smaller; longer tail relative to body size.

Gerbillurus setzeri

Distribution Endemic to Africa. South-West Arid BZ (Namib Desert). Recorded from the Kuiseb R., Namibia, northwards to S Angola (Schlitter 1973).

Habitat Restricted to hot, dry gravel plains with shallow, semi-compacted soil lacking vegetation (Dempster *et al.* 1998). Occasionally disperse to adjacent sand dunes during periods of high population density (Schlitter 1973).

Abundance No detailed data on density, demography, or use of space. Trapping success in suitable habitat ranges from 4% in wet years to 0.1% in drought years. Occasionally, trap success is higher (9%) in selected habitats (Griffin 1990).

Adaptations Terrestrial and nocturnal. Moves by quadrupedal saltation. Excavates burrows in loose soil in dry river washes. Burrows are branched, with two or more entrances, average depth 281 mm and length about 2 m. Burrows contain stored food and nest of shredded vegetation, and provide a stable microenvironment when external conditions are extremely hot or cold.

Avoid extreme aridity and temperature by nocturnal activity and fossorial habits rather than physiological adaptations. Preferred ambient temperature in laboratory trials ca. 28°C, which is the mean burrow temperature in the field. Body temperature ranges from ca. 36°C to 38°C, with good thermoregulation below ambient temperature of 25°C. Reduces overheating above thermoneutral zone (32.2–34.8°C) by increasing dry thermal conductance, accompanied by small increase in oxygen consumption, thus avoiding evaporative water loss for cooling. Relatively large size and thick pelage facilitates thermal conductance and reduces the difference between total water loss and metabolic heat production. Above ambient temperature of 35°C, pulmocutaneous water loss increases sharply, while peripheral vasodilation and piloerection aid cooling. Animals cannot survive ambient temperatures above 35°C for more than one hour.

Low water turnover rate, low faecal water loss and high urinary concentrating ability enable indefinite survival in arid environments without free water. Urine osmolarity varies with diet in laboratory, being higher on a diet of arthropods or seeds without fresh vegetables than on a diet that includes fresh vegetables or water. Urine osmolarity in natural conditions is generally higher than in the laboratory. Urea concentration in urine varies with diet, being higher on seed diet than on arthropod diet. Urinary concentrating ability is the highest of all *Gerbillurus* species, enhanced by the conversion of urea to allantoin. Kidney structure is characterized by extremely long loops of Henle and a well-developed papilla renalis that extends into the ureter, thus promoting very efficient reabsorption of water from urine (Dempster *et al.* 1998).

Foraging and Food Omnivorous. Stomach contents of five individuals contained 50% arthropods, 40% plant material and 10% seeds (Perrin *et al.* 1992). Caches from burrows in C Namibia contained chewed vegetation and arthropod remains (Dempster *et al.* 1998).

Social and Reproductive Behaviour Less active than other *Gerbillurus* species, with little aggressive behaviour in staged laboratory encounters, indicative of a more tolerant social system than in other *Gerbillurus* species. Occasional aggressive bouts include chasing, interspersed with 'boxing', during which antagonists stand upright on toes of hindfeet, and rake each other with forepaws. Mating observed once only: a single mount with intromission, lock and single ejaculation. Copulatory plug deposited with ejaculate. Acoustic communication includes foot drumming with both hindfeet, and ultrasonic whistles at 39–49 kHz. Vocalizations are associated with sexual behaviour and contact-promoting behaviour (Dempster *et al.* 1998).

Reproduction and Population Structure Animals in breeding condition have been trapped throughout the year. Information available for one litter born in captivity. Gestation: 21 days. Litter-size: 3. Young altricial at birth; mean weight at birth: 2.3 g. Growth rate in first 23 days: 0.7 g/day. Eyes open Day 18. Young do not nipple-cling. Young vocalize at audible frequencies and also ultrasonically at 45–55 kHz (Dempster & Perrin 1991b).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Gerbillurus tytonis DUNE HAIRY-FOOTED GERBIL

Fr. Gerbille pygmée des dunes; Ger. Dünen-Zwergrennmaus

Gerbillurus tytonis (Bauer and Niethammer, 1960). Bonn. Zool. Beitr. 10: 236–261 (1959, publ. 1960). Sossusvlei, Namib Desert, Namibia.

Taxonomy Originally described as a subspecies of *Gerbillus vallinus*, but raised to specific rank (as *Gerbillus tytonis*) by Schlitter (1973); and then placed in the genus *Gerbillurus* by Davis (1975a) (see Meester *et al.* 1986). Now assigned to the subgenus *Paratatera* (see

profile genus *Gerbillurus*). Synonyms: none. Chromosome number: 2n = 36, FN = 68 (Schlitter *et al.* 1984, Qumsiyeh *et al.* 1991). Karyotypically similar to *G. paeba*.

Description Small hairy-footed gerbil with white underparts, darker dorsal surface and very long slightly tufted tail. Dorsal pelage rich reddish-brown; dorsal hairs dark at base, changing to reddish-brown distally. Ventral pelage white from chin to tail tip, extending to fore- and hindfeet and well up on to flanks. Sharp delineation between dorsal and ventral pelage colours. Head narrow, with pointed nose. Sides of muzzle white. Large eyes with small white supraorbital patch. Ears long and rounded, sparsely haired, paler than dorsal pelage, with narrow fringe of black pigmentation on lateral margin. Hindlimbs much longer than forelimbs. Fore- and hindfeet pure white, five digits each foot, Digit 5 on forefoot reduced. Hindfeet elongated with splayed digits; soles well furred, with distinctive fringe of hair along sides of each digit. Tail long (ca. 128% of HB), brown above, white below with variable pencil of greyish hairs at distal end. Skull: extremely short posterior palatal foramina (0.6–1.6 mm, $n = 57$); auditory bullae inflated (9.3–10.4 mm long) extending posteriorly to occiput. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

G. paeba. Paler colour; narrower hindfeet without distinctive fringe on digits.

G. setzeri. Paler colour; on average larger; narrower hindfeet without distinctive fringe on digits.

G. vallinus. Darker colour; narrower hindfeet without distinctive fringe on digits.

Distribution Endemic to Africa. South-West Arid BZ (Namib Desert). Recorded only from coastal and inland dune systems of SW Namibia, from Swakopmund to Luderitz.

Habitat Restricted to hot, dry areas of shifting red sand-dunes of the Namib Desert where mean annual temperature exceeds 18 °C

Gerbillurus tytonis

and mean annual rainfall is less than 125 mm. Prefers zones within the dune system with comparatively high plant species richness (2–3 species), and avoids compact soils such as inter-dune valleys (Perrin & Boyer 1996). Digs burrows in sand stabilized by *Trianthema hereroensis* or *Stipagrostis sabulicola* and in islands of microhabitat formed by nara (*Acanthosicyos horrida*) (Hughes *et al.* 1994, Perrin *et al.* 1999b). In the dry Swakop river bed, prefers nara (*Acanthosicyos horrida*) habitat to adjacent grassland, where it occurs sympatrically with *Rhabdomys pumilio*.

Abundance The most abundant species of rodent occurring in the Namib Desert sand sea, and the only gerbil species permanently resident in this habitat. Population density varies from low in summer to high in autumn: 2–18.2/ha at Bushman's Circle, 0.3–6.3/ha at Far East and 0.8–7.8/ha at Nara Valley (Perrin & Boyer 2000).

Adaptations Terrestrial and nocturnal. Moves by quadrupedal saltation, leaping up to 41 cm in a single hop in open habitat. Sandbathes frequently to maintain coat condition. Burrows are branched or unbranched, having one or two entrances, with an average depth of 285 mm and about 1 m long. Burrows contain a nest of shredded vegetation and food caches.

Avoids extreme aridity and temperature by nocturnal activity and fossorial habits rather than physiological adaptations. Preferred ambient temperature in laboratory trials ca. 28 °C, slightly lower than mean burrow temperature (30 °C) in the field. Regulates body temperature at ca. 35–37 °C over range of ambient temperatures of 5–30 °C. Above ambient temperature of 35 °C, pulmocutaneous water loss increases sharply, while peripheral vasodilation and piloerection aid cooling. Animals cannot survive ambient temperatures above 35 °C for more than one hour. Energy is conserved by having lower basal metabolic rate at thermoneutrality (32.4–34.9 °C) and slightly lower thermal conductance than expected for body mass. Behavioural avoidance of high temperatures reduces the need for costly evaporative cooling mechanisms, thus conserving energy and water.

Field water turnover rate almost twice as high in summer as in winter, and is associated with change in diet. Urine osmolality varies with diet in laboratory, being higher on diets of arthropods or seeds without fresh vegetables than diets including fresh vegetables or drinking water. Urine osmolality in natural conditions is generally higher than laboratory measurements. Maintains body mass without access to succulent vegetation or drinking water, provided that diet includes arthropods; loses body mass on dry seeds alone.

Urea concentration in urine varies with diet, being higher on seed diet than on arthropod diet. Urine contains crystalline allantoin, which aids hyperosmotic urine production. Elongated papilla renalis extends into the ureter, promoting reabsorption of water from urine (Perrin *et al.* 1999b).

Foraging and Food Omnivorous and opportunistic. Diet contains more seeds in winter than in summer (0.2–33% in winter, 0–9.5% in summer), more green plant material in spring and summer than winter (28.8–57.7% in summer, 0.9–28% in winter), and more invertebrates in spring and summer than during other seasons (9.4–94% in summer, 23.5–75% in winter). Considerable variation exists between individuals, localities and seasons (Perrin *et al.* 1999b). In nara habitat, foraging activity decreases at periods of full moon and

decreases in the presence of competitors such as *Rhabdomys pumilio*. High predation risk in grassland habitat results in lower levels of foraging activity than in nara habitat (Hughes *et al.* 1994).

Social and Reproductive Behaviour The most aggressive and active of all *Gerbillurus* species. Dominance established in laboratory encounters by prolonged chasing rather than by contact fighting. Agonistic behaviour includes frequent bouts of mutual boxing, with both antagonists standing upright on toes of hindfeet. Males identify oestrous ♀♀ by chemosignals deposited on substrate during urination, defecation, sandbathing or walking. Mating observed twice: copulation characterized by lock lasting 20–26 sec and a single ejaculation. Copulatory plug deposited with ejaculate.

Acoustic communication includes footdrumming with both hindfeet and ultrasonic calls in the form of ‘stuttering’ (a series of clicks at 11–34 kHz) and strongly modulated whistles at 48–63 kHz. Vocalizations are associated with sexual and contact-promoting behaviour, and rarely accompany non-contact and agonistic behaviour. Ultrasonic vocalizations accompanied copulation in two observed copulations (Perrin *et al.* 1999b).

Reproduction and Population Structure Reproduction is seasonal, with peak recruitment during summer. Adult ♂♂ have scrotal testes throughout the year, whereas only 25–50% of adult ♀♀ are reproductively active during summer (Dec–May) and no ♀♀ are reproductively active during winter (May–Nov) (Perrin & Boyer 2000). Oestrous cycle lasts six days. Litter-size in captivity:

4.4 (2–6, *n* = 7 litters). Young altricial at birth; mean weight at birth: 1.9 g (*n* = 22). Growth rate in first 28 days: 0.4 g/day. Hair visible Day 10–13. Eyes open Day 22–24. Young do not nipple-cling (Perrin *et al.* 1999b).

Predators, Parasites and Diseases Major predators are Spotted Eagle-owls *Bubo africanus* and Black-backed Jackals *Canis mesomelas*.

Conservation IUCN Category: Least Concern.

Gerbillurus vallinus BRUSH-TAILED HAIRY-FOOTED GERBIL

Fr. Gerbille pygmée à queue touffue; Ger. Pinselschwanz-Zwergmaus

Gerbillurus vallinus (Thomas, 1918). Ann. Mag. Nat. Hist., ser. 9, 2: 148.

Tuin, near Kenhart, Hartebeest R., 29° S 21° E, Bushmanland, Northern Cape Province, South Africa.

Taxonomy Originally described in genus *Gerbillus*, and reallocated to *Gerbillurus* by Davis (1975a). Together with *G. setzeri*, assigned to subgenus *Gerbillurus* (see profile Genus *Gerbillurus*). Karyotypically similar to *G. setzeri*. Synonyms: *seeheimi*. Subspecies: two. Chromosome number: 2*n* = 60, FN = 80, with individual variation in the number of autosomal arms (Schlitter *et al.* 1984, Qumsiyeh *et al.* 1991). Karyotypically similar to *G. setzeri*.

Description Small hairy-footed gerbil with white underparts, dark dorsal surface and very long tail. Dorsal pelage, flanks and outer surface of limbs reddish-brown to dark greyish-brown. Ventral pelage white from chin to tip of tail, extending to forelimbs and feet. Head narrow, with pointed nose and long vibrissae. Sides of muzzle pale. Large eyes with variable off-white supraorbital patch, not always discernible. Ears long and rounded, paler than dorsal pelage; white patches in front of and behind ears, not always discernible. Hindlimbs much longer than forelimbs. Forefeet and hindfeet pure white, five digits each, Digit 5 on forefoot reduced. Hindfeet elongated; soles partially furred. Tail relatively long (ca. 140% of HB), covered with dense short hairs, with dark dorsal tail stripe at least halfway to end of tail; well-developed pencil, deep red to black. Skull: posterior palatal foramina comparatively

long (2.0 [1.4–2.5] mm); auditory bullae inflated posteriorly and laterally (oblique length 10–11 mm); bullae extends posteriorly beyond occiput. Nipples: 1 + 2 = 6.

Geographic Variation

G. v. vallinus: Northern Cape Province, South Africa; dorsal pelage dark reddish-brown; width across M³–M³ ca. 6.3 mm.

G. v. seeheimi: S Namibia; dorsal pelage grey; width across M³–M³ ca. 5.1 mm.

Similar Species

G. paeba. Similar colour where sympatric; on average smaller; tail shorter and relatively shorter without distinct pencil.

G. setzeri. Paler colour; larger size; tail shorter and relatively shorter without distinct pencil.

G. tytonis. Similar colour; slightly smaller; tail shorter but relatively longer without distinct pencil.

Distribution Endemic to Africa. South-West Arid BZ (Namib Desert, Karoo). Northern limit is around Solitaire, Namibia, extending southwards to Sutherland and eastwards to De Aar, Northern Cape Province, South Africa. Isolated population occurs

on Tsondeb River flood-plain, Namibia (Erasmus & Rautenbach 1984, Griffin 1990, B. H Erasmus unpubl.).

Habitat Restricted to areas of bare gravel, or shallow sand overlying gravels, with scant vegetation. In Northern Cape Province, burrows are constructed in mounds of loose soil around the base of bushes, particularly *Phaeoptilum spinosum* and *Rhigozum trichotomum* (Dempster *et al.* 1999).

Abundance Most abundant rodent species trapped in some areas at times, e.g. Brukaros–Berseba in Namibia. No numerical data available (Griffin 1990).

Adaptations Terrestrial and nocturnal. Moves by quadrupedal saltation. Sandbathes frequently to maintain coat condition. Excavates complex burrows; entrances 6–9 cm in diameter. Burrows contain insect remains, leaves and seeds, and a nest of shredded vegetation; and they provide a stable ambient temperature and relative humidity during the day.

Avoids extreme aridity and temperature by nocturnal activity and fossorial habits rather than physiological adaptations. Body temperature ranges from ca. 37°C to 38°C, with good thermoregulation below ambient temperature of 25°C. Reduces overheating above thermoneutral zone (33.1–35.0°C) by increasing dry thermal conductance, accompanied by a small increase in oxygen consumption, thus avoiding evaporative water loss for cooling. Relatively large size and thick pelage reduces thermal conductance at temperatures below 30°C; but above 30°C, dry thermal conductance and pulmocutaneous water loss increase sharply, thus facilitating cooling. Unable to survive ambient temperatures above 35°C for more than one hour.

Good ability to vary the concentration of the urine enables adjustment of the water turnover rate. This rate is also affected by variations in the protein content and potential water yield of the diet. Urine osmolarity is higher on diets that contain arthropods or seeds

without fresh vegetables than on diets that include fresh vegetables or drinking water; it is also higher on seed diets than arthropod diets. Body mass can be maintained without access to succulent vegetation or drinking water, provided that diet includes arthropods; body mass is lost on diet of dry seeds alone.

Urea concentration in urine varies with diet, being higher on a seed diet than on an arthropod diet, and higher on diets excluding water than on diets with access to drinking water. Urine contains more crystalline allantoin than in other *Gerbillurus* species, thereby conserving water. Urinary concentrating ability is facilitated by an elongated papilla renalis, which extends into the ureter (Dempster *et al.* 1999).

Foraging and Food Omnivorous. Remains of insect exoskeletons, monocotyledonous leaves and seeds reported in burrows at Kenhardt, Northern Cape Province, South Africa (Dempster *et al.* 1999).

Social and Reproductive Behaviour Gregarious, and less aggressive than other *Gerbillurus* species in staged encounters. Individuals tend to huddle together, sniff each other frequently and follow each other. Occasional aggressive bouts include chasing, interspersed with 'boxing', during which antagonists stand upright on toes of hindfeet and rake each other with forepaws. Females differentiate between conspecific and heterospecific ♂♂ by odours deposited on the substrate during urination, defecation, sandbathing or walking, while ♂♂ show no evidence of discrimination between odours of different species (Dempster & Perrin 1990). Acoustic communication occurs by footdrumming, when both hindfeet strike the ground alternately in short bursts of drumming, by modulated audible whistles at ca. 12 kHz, and by strongly modulated ultrasonic whistles at 22–40 kHz with a duration of 44 msec. Vocalizations are associated with sexual and huddling behaviour, and frequently follow sniffing and aggressive behaviour (Dempster *et al.* 1999).

Reproduction and Population Structure Proportion of pregnant and lactating ♀♀ in a population in Northern Cape Province was higher in summer than in winter (B. Erasmus & M. Linger unpubl.). Litter-size (in wild and captivity): 3 (1–5, n = 5 litters; Dempster & Perrin 1991a). Young altricial at birth, weight 2.0 g (n = 8). Growth rate 0.4 g/day for first 23 days after birth. Hair visible Day 4–6. Incisors erupt Day 11–12. Eyes open Day 16–20. Weaned at Day 23–28. Young vocalize at audible frequencies and also ultrasonically at 45–55 kHz. Young do not nipple-cling (Dempster & Perrin 1991a).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

GENUS *Gerbillus*

Gerbils

Gerbillus Desmarest, 1804. Tabl. Méth. Hist. Nat. In: Nouv. Dict. Hist. Nat. 24: 22.

Type species: *Gerbillus aegyptius* Desmarest, 1804 (= *Dipus gerbillus* Olivier, 1801).

Gerbillus gerbillus.

The genus *Gerbillus* is distributed in Sahara Arid, Sahel Savanna and Somalia–Masai BZs of Africa, and extraliminally throughout the Middle East to India. Gerbils are particularly abundant on sandy soils in arid and semi-arid habitats, but they may also be found on more clayey soils and even in rocky habitats. The number of species present in Africa is uncertain (see hereunder), but 35 species have been considered sufficiently well supported to be treated here.

Gerbillus species are small to very small rodents, characterized by a usually pale-coloured pelage, relatively large eyes and a tail longer (or much longer) than head and body, often with a terminal pencil or tuft of longer hairs. Depending on the species, soles of the hindfeet are naked, hairy, or intermediate (partially haired), whereas they are always naked in *Taterillus* and *Gerbillurus* (= *Tatera*). The skull is characterized by a variable but often important development of the auditory bullae and of the mastoid bones, which are visible when the skull is viewed from above (Figure 50). However, the mastoids do not project posteriorly to the same extent as in *Meriones*.

Gerbils are usually terrestrial and nocturnal, and actively dig burrows that can reach an impressive size (several metres when the various gallery lengths are added) and depth (up to 1 metre). They are predominantly granivorous, although a number of species also consume green vegetation and/or insects. Desert species show physiological and behavioural adaptations for water retention, such as lethargy or aestivation deep inside plugged burrows. Populations of some species may reach very high densities, and constitute a threat to agriculture in some regions (e.g. *G. nigeriae* in the Sahel Savanna BZ).

Taxonomically, *Gerbillus* is probably one of the most problematic genera of mammals. Species limits are not well-defined in a number of cases, due to the relatively great morphological homogeneity within

Figure 50. Skull and mandible of *Gerbillus pyramidum* (HC 291).

species groups. As a result, many forms considered as valid species by some authors may finally prove to be synonymous with other species, an option that we have adopted here for a small number of taxa considered as potentially valid species by Lay (1983) and Musser & Carleton (2005). Besides, we have decided to consider the following taxa as *incertae sedis*: *G. agag*, *G. burtoni*, *G. grobbeni*, *G. jamesi*, *G. muriculus*, *G. principulus*, *G. syrticus* and *G. vivax*. Opinions on these taxa have been highly variable, and many of them are known only from a very small number of individuals from the type locality. Moreover, virtually nothing is known of their biology. A careful re-examination of the taxonomic status of these taxa is needed before their possible species-specific attributes can be ascertained. Three recognized as species by Musser & Carleton (2005), namely *dongolanus*, *garamantis* and *mauritaniae*, are here regarded as synonyms.

Musser & Carleton (2005) decided to separate *Dipodillus* from *Gerbillus*, but they presented it, quoting Pavlinov, rather as a 'working hypothesis' than a definite arrangement, so we decided not to follow this decision here. Also, various subgeneric subdivisions have

been proposed for the genus, but the criteria used have proved to be ambiguous, and it seems better not to recognize any subgeneric distinction in the present state of knowledge. To distinguish between species, morphological criteria such as body size, nature of the soles of the hindfeet (naked, hairy or intermediate), presence or absence of an accessory tympanum, relative size of the bullae, and molar morphology are of some help. However, as in many other genera of African rodents, the karyotype appears as an especially informative and unambiguous diagnostic, species-specific character in this genus. In future, the use of chromosomal techniques on samples from as many

localities as possible (including type localities) will undoubtedly help to clarify the content of this genus.

Here 36 species are recognized. Species are distinguished on size, relative length of tail, presence/absence of pencil at tip of tail, presence/absence of supraorbital and postauricular white patches, size of bullae and chromosome number (Table 25). The hairiness of the sole of hindfoot (often used to distinguish *Gerbillus* from *Dipodillus*) is useful in some situations.

Laurent Granjon

Gerbillus acticola BERBERA GERBIL

Fr. Gerbille de Berber; Ger. Berbera-Rennmaus

Gerbillus acticola Thomas, 1918. Ann. Mag. Nat. Hist., ser. 9, 2: 147. Berbera, Somalia.

Taxonomy Petter (1975a) refers to *acticola* as a subspecies of *G. pyramidum*. In contrast, Lay (1983) points out that the nearest populations of *G. pyramidum* are more than 1300 km away (and separated by many unsuitable habitats) and suggests *acticola* should be retained as a distinct species pending further studies. Synonyms: none. Chromosome number: not known.

Description Small gerbil. Dorsal pelage sandy-orange; dorsal hairs grey, with sandy-orange tips. Flanks slightly paler than back, hairs white with pale sandy-orange tips. Ventral pelage pure white, clearly delineated from colour on flanks. Crown of head sandy-orange, with white supraorbital white patch. Cheeks, throat, fore- and hindfeet white. Soles of feet naked. Tail long (ca. 140% HB), bicoloured; sandy-orange above, paler or white below. Longer brown and white hairs form narrow pencil at tip of tail. Auditory bullae large (ca. 37% of GLS).

Geographic Variation None recorded.

Similar Species

G. pyramidum. Similar in general size and colour; different geographic range.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Only known from three localities, all in N Somalia (Berbera [type], Bulhar on the coast, and Buras at 3500 ft).

Habitat Field notes record ‘caught near wells’ and ‘caught on sandy plain’ on the coast near Bulhar.

Abundance Only a few specimens of this species have been collected (1910–30).

Remarks Juvenile and subadult individuals found in Apr–May and Nov–Dec.

Conservation IUCN Category: Data Deficient.

***Gerbillus amoenus* CHARMING GERBIL (PLEASANT GERBIL)**

Fr. Gerbille charmant; Ger. Anmutige Rennmaus

Gerbillus amoenus (de Winton, 1902). Ann. Mag. Nat. Hist., ser. 7, 9: 46. Giza Province, Egypt.

Taxonomy Originally described in the genus *Dipodillus*. Historically the taxonomic status of *amoenus* has been uncertain, and it has been regarded as either a subspecies of, or synonymous with, *G. dasyurus*, *G. campestris* and *G. nanus* (Osborn & Helmy 1980). Following Wassif (1956), *amoenus* is considered a valid species by Osborn & Helmy (1980), Lay (1983) and Musser & Carleton (1993, 2005). Referred to as *Dipodillus amoenus* by Osborn & Helmy (1980). Synonyms: *vivax*. Subspecies: two. Chromosome number: $2n = 52$ (Lay 1983).

Description Small to very small brownish gerbil with large area of white on rump. Pelage short and soft. Dorsal pelage cinnamon to dark yellowish-brown; dorsal hairs grey at base, with yellowish subterminal band and usually with black tip. White on rump close to base of tail. Flanks yellowish; hairs white at base. Ventral pelage pure white. Head with conspicuous supraorbital and postauricular patches, and broad line of black-tipped hairs from base of eye to base of ear. Ears large, pigmented at tip. Chin, throat and chest white. Upper surface of limbs white. Soles of hindfeet naked, not pigmented. Tail long (ca. 130% of HB), bicoloured, cinnamon to dark yellowish-brown above, white below; brownish inconspicuous pencil on terminal one-quarter of tail. Nipples: not known.

Geographic Variation There appears to be little variation within the species in Egypt, but Ranck (1968) reports decreased size and reduction in the size of the auditory bulla from west to east in Libya. Mean external measurements are slightly larger in Libyan populations than in Egyptian populations (*amoenus*). Two subspecies have been described (see Ranck 1968, Osborn & Helmy 1980).

G. a. amoenus: Egypt. As above.

G. a. vivax: Libya. Paler in colour, larger in total length, and with larger pencil on tail.

Similar Species (size comparisons refer to mean values only)

G. gerbillus. Smaller; white rump patch present; pencil of dark hairs on tail; chromosome number: $2n = 42$ (♀ ♀), $2n = 43$ (♂ ♂).

G. simoni. HB of similar size; white rump patch and white markings on head absent; tail shorter without pencil; chromosome number: $2n = 60$, FN = 68, 69.

G. campestris. Larger, pelage long and soft; supraorbital and postauricular patches inconspicuous or not present; white rump patch absent; tail with conspicuous pencil; chromosome number: $2n = 56$ and 58, FN = 68.

G. henleyi. Smaller; white rump patch prominent in specimens from Egypt, less so in specimens from West Africa; tail with thin pencil; chromosome number: $2n = 52$, aFN = 58–62.

Distribution Endemic to Africa. Sahara Arid BZ. Recorded from Egypt and Libya. In Egypt, recorded west of Nile Delta, in the Western Desert and in the southern part of Eastern Desert (Osborn & Helmy 1980). In Libya, occurs in many habitats throughout much

*Gerbillus amoenus*

of the country. The Egyptian and Libyan populations appear to be well separated from each other. Although Osborn & Helmy (1980) suggest that the species may possibly occur also in Tunisia, Algeria, Morocco and Mauritania, there are no records from these countries (Aulagnier & Thévenot 1986, Kowalski & Rzebik-Kowalska 1991, Musser & Carleton 1993, 2005).

Habitat Very varied: recorded in cultivated fields, on grassy canal banks, under tamarisk trees, under fallen fronds of date palms, in loose sand, in several types of semi-desert from regions with dense plant cover to barren hamadas, and in salt marshes. Has been found in tents set in semi-desert habitats. Avoids areas of permanent sand dunes (Ranck 1968, Osborn & Helmy 1980).

Abundance No detailed information; Ranck (1968) records that it is a common rodent in oases in Libya, and that it is usually less abundant than other species of sympatric gerbils.

Remarks Nocturnal and terrestrial. Burrows are simple and usually not deeper than ca. 25 cm (Ranck 1968), and often are excavated under bushes (e.g. under *Zilla spinosa* bushes in Egypt; Hoogstraal *et al.* 1957b). Sometimes individuals are found in the burrows of the larger *Psammomys* spp. Appears to be very tolerant of a wide range of environmental conditions. In Egypt, sympatric gerbils include *G. simoni*, *G. henleyi* and *G. campestris* in salt marshes, and *G. gerbillus* and *G. campestris* in sandy semi-desert areas (Osborn & Helmy 1980). A low incidence of infection with fleas has been recorded on 9 out of 40 individuals. Three species of fleas were

recorded: *Synosternus cleopatrae* (the commonest species), *Xenopsylla ramesis* (on individuals) and *Nosopsyllus henleyi* (in nests). All species of fleas have been recorded also on other species of gerbils (Hoogstraal & Traub 1965a).

Conservation IUCN Category: Data Deficient.

Gerbillus andersoni ANDERSON'S GERBIL

Fr. Gerbille d'Anderson; Ger. Andersons Rennmaus

Gerbillus andersoni de Winton, 1902. Ann. Mag. Nat. Hist., ser. 7, 9: 45. Mandara, E Alexandria, Egypt.

Taxonomy The definition of this species is uncertain. In Egypt, Osborn & Helmy (1980) recognize three subspecies – *inflatus* in the coastal Western Desert, *andersoni* in the Nile Delta and *bonhotei* in northern Sinai. In contrast, Musser & Carleton (1993), following Lay (1983), regard *inflatus* and *bonhotei* as separate species. Ranck (1968) referred to *G. eatoni* and *G. inflatus* in Libya, and suggested that three closely related species occur along the North African coast: *G. eatoni* in the west (Libya and W Egypt), *G. andersoni* in the middle and *G. bonhotei* in the east. Musser & Carleton (1993, 2005) consider *eatoni* to be a synonym of *G. andersoni*. Here, *G. andersoni* is considered to include *inflatus* and *bonhotei* (following Osborn & Helmy 1980 and Musser & Carlton 2005), perhaps with subspecific status. Synonyms: *allenbyi*, *blanci*, *bonhotei*, *eatoni*, *inflatus*, *versicolor*. Subspecies: none recognized here. Chromosome number: 2n = 40, FN = 80 (Egypt; Lay *et al.* 1975).

Description Small gerbil. Dorsal pelage sandy-orange to orange-brown, lightly suffused with black along mid-dorsal line; dorsal hairs medium grey on basal half, orange-brown on terminal half; black tips on some hairs. Flanks paler than back; hairs white with orange tip. Ventral hairs pure white, clearly delineated from colour of flanks. Crown of head and nose similar to back. Inconspicuous supraorbital and postauricular white patches. Broad conspicuous band of dark-tipped hairs from nasal region, below eye to base of ear. Limbs and feet white. Soles of feet hairy and pigmented. Tail long (ca. 115–140% of HB), sparsely covered with short orange-brown hairs above, paler below; small rather inconspicuous pencil of brownish hairs at tip of tail. Nipples: not known.

Geographic Variation Six taxa have been named as subspecies but their value is dubious (see above): *bonhotei* (North Sinai and Jordan), *andersoni* (Nile Delta), *inflatus* (Western Desert of Egypt, eastern desert of Libya), *eatoni* (central coast of Libya), *versicolor* (central coast of Libya) and *blanci* (Tunis area). Differences include minor variations in pelage colouration (probably related to variation in sand and soil colour and moisture), overall size and extent of inflation of auditory bullae.

Gerbillus andersoni

Similar Species

G. campestris. Well-developed pencil on tail, naked soles.

G. gerbillus. Paler colour; large white rump patch, soles of feet not pigmented, conspicuous pencil on tail.

Distribution Sahara Arid BZ. Recorded from coastal regions of North Africa from about 16°E in Libya to about 34°E in North Sinai. An isolated population occurs in Tunisia in the region of Tunis (ca. 10°E). Apparent gaps in distribution along the coast may be due to inadequate surveys or lack of suitable habitat. Also recorded from Israel, Jordan and N Saudi Arabia (Harrison & Bates 1991).

Habitat Sandy habitats such as palm groves, cultivated and abandoned semi-desert, and vegetated sandy areas in oases. Also lives in coastal white sand dunes covered with *Atriplex* shrubs, in salt

marshes close to sedges, and in depressions containing sandy loam and *Artemisia* shrubs.

Abundance Common in the sandy areas of the Nile Delta and in the coastal parts of the Western Desert in Egypt (Hoogstraal 1963).

Adaptations Nocturnal and terrestrial. Rests in burrows during the day.

Foraging and Food Omnivorous; forages for food at night. On an annual basis, diet consists of 35% seeds (*Thymelaea* 25%, *Anabasis* 2%, *Cutandia* 1%), 19% leaves, 15% bulbs of iris, 8% other plants and 20% insects. Each of these items varies on a seasonal basis, e.g. in winter, during the wet season and when it is relatively cool, leaves form the major item of the diet (leaves 85%, seeds of *Thymelaea* 10%, insects 5%); during summer when hot and dry, the diet is more varied and includes a greater proportion of water-containing foods (insects 30%, bulbs 25%, leaves 10%, other plants 25% and seeds 10%) (Soliman & Wassif 1982). At other seasons, the mix of foods is somewhere between these extremes.

Social and Reproductive Behaviour Anderson's Gerbils live syntopically with several other species of small rodents including *G. gerbillus*, *G. perpallidus*, *G. amoenus*, *G. simoni*, *Meriones shawi*, *Psammomys obesus* (Osborn & Helmy 1980). Interactions between these species have not been studied.

Reproduction and Population Structure In Western Desert of Egypt (Wassif & Soliman 1980), ♀♀ are reproductively active in winter (Jan–Feb) and spring (Feb–May), with a peak in Jan–Mar. Males with scrotal testes (and max weight of testes) Nov–Jun with peak in Dec–Apr (>50% ♂♂ active). Reproduction strongly seasonal, with juveniles entering population in winter and spring (Feb–May/Jun). These individuals breed in following Jan–Mar (when ca. 8–12 months old) and form ca. 70% of breeding population; some older individuals (up to 30% of population) survive to breed during a second reproductive season (when ca. 18–24 months old).

Litter-size: 3.9 (3–7, $n = 10$). Some ♂♂ reproductively active at 5.5 months of age and weight 20 g, but most not until ca. 30 g.

In winter (Jan–Feb), at commencement of reproduction, population composed of two cohorts: adults (now 8–12 months) form 70–85% of population, and older adults (18–24 months) form 15–30% (see also above). During Mar–Aug, juveniles born in Jan–Apr form an increasing proportion of population, so by midsummer (Aug), population composed of 70% juveniles and 30% adults (now 13–18 months). During Aug–Dec, the proportion of juveniles gradually declines as these individuals become adults, and the adults who reproduced during the previous winter (now 18–20 months) form the older adult cohort.

Predators, Parasites and Diseases Six species of fleas have been recorded, the commonest being *Synosternus cleopatrae*, which is found also on many other species of gerbils (Hoogstraal & Traub 1965a).

Conservation IUCN Category: Not Evaluated.

Gerbillus bottai BOTTA'S GERBIL

Fr. Gerbille de Botta; Ger. Bottas Rennmaus

Gerbillus bottai Lataste, 1882. Le Naturaliste 4: 36. Sennar, Sudan.

Taxonomy The status of *bottai* is uncertain. Kock (1978a) regarded *G. bottai* to include *G. harwoodi* and *luteolus*, whereas Petter (1975a) kept *G. bottai* and *G. harwoodi* as valid species and placed *luteolus* within *G. campestris*. Lay (1983) and Musser & Carleton (1993) maintain *G. bottai* and *G. harwoodi* as valid species and place *luteolus* as a synonym of *G. stigmonyx* (= *Dipodillus stigmonyx* in Musser & Carleton 2005). It is of interest to note that *G. bottai* and *G. stigmonyx* are sympatric in the region between the Blue and White Nile rivers south of Khartoum, whereas *G. harwoodi* occurs only in Kenya, about 1200 km to the south in a completely different environment; this suggests that *G. harwoodi* should be regarded as a valid species distinct from *G. bottai* and *G. stigmonyx* (including *luteolus*). Musser & Carleton (2005) refer to this species as *Dipodillus bottai*. The taxa *bottai*, *stigmonyx* and *watersi*

may form a closely related species complex, and may even belong to the same species (F. Dieterlen, in litt.); all three are sympatric within an area of N Sudan bounded by 30–38°E and 20–28°N. Synonyms: none. Chromosome number: not known.

Description Small gerbil. Dorsal pelage sandy-brown, suffused with black especially on mid-dorsal line. Dorsal hairs rather short, dark grey at base, sandy-brown at terminal end, sometimes with black tip. Flanks paler than back, hairs white with orange-brown tips. Ventral pelage pure white. Nose and crown of head sandy-brown. Supraorbital and postauricular white patches. Ears orange-brown at base, black on tips. Chin and throat white. Limbs white. Soles of feet hairy or slightly hairy. Tail long (ca. 125% HB), slightly bicoloured;

short blackish-brown hairs above, paler below. Hairs at tip slightly longer forming ill-defined pencil.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Three species are sympatric with *G. bottai*:

G. stigmonyx. Similar in general size; larger auditory bullae; rare.

G. watersi. Smaller HB and T; dorsal pelage pale orange clearly delineated on flanks from white ventral pelage; uncommon.

G. pyramidum. Larger HB; darker dorsal pelage; common.

Distribution Endemic to Africa. Sahel Savanna BZ. Known only from a small region between the White Nile and Blue Nile rivers south of Khartoum, Sudan.

Habitat Specimens have been found in fields of vegetables and cereals close to the Nile Valley near Khartoum (F. Dieterlen in litt.).

Abundance Rare. Known only from a few specimens at four or five localities.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Gerbillus brockmani BROCKMAN'S GERBIL

Fr. Gerbille de Brockman; Ger. Brockmans Rennmaus

Gerbillus brockmani (Thomas, 1910). Ann. Mag. Nat. Hist., ser. 8, 5: 420. Burao, 85 miles south of Berbera, Somalia.

Taxonomy Lay (1983) and Musser & Carleton (1993) regard *brockmani* as a valid species. Petter (1975a) considered *brockmani* to be a subspecies of *G. nanus* but this seems unlikely since the distribution of *G. nanus* is far removed from that of *brockmani*. Very similar to *G. somalicus* (considered as subspecies of *G. campestris* by Petter 1975a), which also occurs in N Somalia; a comparative study of the two species would be instructive. Synonyms: none. Chromosome number: not known.

Description Very small gerbil. Dorsal pelage sandy-orange to sandy-brown, long and soft. Dorsal hairs medium grey with subterminal orange band, some with black tip. Flanks paler. Ventral pelage pure white (one specimen has pale golden ventral pelage). Crown of head and nose sandy-brown. White supraorbital patch and inconspicuous white postauricular patch. Chin, cheeks and throat white. Upper surface of limbs and feet orange-brown. Soles of hindfeet naked. Tail long (ca. 140% of HB), with short sandy-brown

and black bristles. Longer hairs form small pencil on terminal one-third of tail. Cheekteeth very small; auditory bullae relatively large (ca. 37% of GLS).

Geographic Variation None recorded.

Similar Species

G. somalicus. On average slightly larger; larger M¹–M³.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Only known from type locality, Burao, in N Somalia.

Habitat No information; type locality is in dry hilly country south of Berbera.

Abundance Presumably rare; only a few specimens are known.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Measurements

Gerbillus campestris NORTH AFRICAN GERBIL

Fr. Gerbille des champs; Ger. Nordafrikanische Rennmaus

Gerbillus campestris (Loche, 1867). Expl. Sci. Alg. Zool. Mamm., p. 106. Philipeville, Constantine Province, Algeria.

Taxonomy Originally described in the genus *Dipodillus*. The widespread distribution of this species has resulted in many forms being described either as species or subspecies. Lay (1983) lists 19 forms that have been regarded by various authors as synonyms of *campestris*. Of these, Lay (1983) and Musser & Carleton (1993) consider 13 to be synonyms (because of misidentification, incorrect taxonomy or very little data), and six as valid species pending further studies (*amoenus*, *jamesi*, *lowei*, *quadrimaculatus*, *somalicus*, *stigmonyx*). Here, four of these taxa are regarded as distinct species (*amoenus*, *lowei*, *somalicus*, *stigmonyx*), *jamesi* as *incertae sedis*, and *quadrimaculatus* as a synonym of *G. campestris*. All six taxa have very limited distributions and are known by only a few specimens. Some of the synonyms may, perhaps, be regarded as subspecies. Musser & Carleton (2005) refer to this species as *Dipodillus campestris*. Synonyms: *brunnescens*, *cinnamomeus*, *dodsoni*, *gerbii*, *haymani*, *hilda*, *minutus*, *patrizi*, *quadrimaculatus*, *riparius*, *rozsikae*, *somalicus*, *venustus*, *wassifi*. Subspecies: none; some of the synonyms may perhaps represent subspecies but none are recognized here. Chromosome number: 2n = 56 (specimens from Morocco, Algeria, Tunisia and Egypt; Lay *et al.* 1975); chromosomal polymorphism (2n = 56 and 58) from one locality in Morocco (Lay *et al.* 1975); 2n = 56, FN = 68 (Niger; Dobigny *et al.* 2002b).

Description Small orange-brown gerbil with long soft pelage and long tail with well-developed pencil. Hairs long and soft, more so than in other species of gerbils. Dorsal pelage cinnamon to orange-brown (with various shades of darkness). Dorsal hairs grey at base with sandy-brown or golden-brown terminal band, sometimes with black tip. Flanks paler than back. Ventral pelage

pure white, clearly delineated from flanks. Crown of head and nose similar to dorsal pelage, sometimes with longitudinal black stripe on nose. Supraorbital and postauricular patches inconspicuous or not present. Cheeks, chin and throat white. Limbs whitish. Feet whitish, sometimes suffused with golden-brown. Soles of hindfeet naked and darkly pigmented. Tail long (ca. 140% of HB), bicoloured, golden-brown above, well covered with small golden or blackish hairs, white below. Terminal half with well-developed pencil of long hairs.

Geographic Variation Dorsal pelage of individuals varies according to locality and substrate. Individuals from sandy areas are pale orange-brown suffused with grey; those from coastal regions are medium orange-brown, sometimes suffused with black. Individuals from rocky areas in the south (e.g. Sudan, as *G. c. venustus*; see Happold 1967b) are blackish golden-brown with most dorsal hairs tipped with black. Size and density of pencil varies geographically.

Similar Species

G. amoenus. Smaller in all mean measurements (although some overlap in ranges); head with conspicuous supraorbital and postauricular patches; broad line of black-tipped hairs from base of eye to base of ear; chromosome number: 2n = 52; Libya and Egypt.

G. andersoni. HB (mean 92 mm) and T (mean 124 mm) smaller, but with overlap in ranges; mean HF longer (29 mm); head with inconspicuous supraorbital and postauricular white patches; broad conspicuous line of dark-tipped hairs from nasal region, below eye to base of ear; chromosome number: 2n = 40, FN = 80; coastal regions of north-east Africa.

G. dasyurus. Smaller in all mean measurements (although some overlap in ranges); head with indistinct supraorbital and supraauricular patches; line of black-tipped hairs from base of eye to base of ear; chromosome number: $2n = 60$, $FN = 69/70$; NE Egypt, east of Nile R.

G. hoogstraali and *G. mahgrebi*. May be sympatric in Morocco.

Distribution Endemic to Africa. Sahara Arid, Mediterranean Coastal and Sahel Savanna BZs. Widespread in coastal regions from Morocco to Egypt, and southwards into the semi-deserts and deserts of Algeria, Libya and Egypt. Isolated populations in Mali (Adrar des Iforas), Niger (Air) (Dobigny *et al.* 2002b) and in rocky areas of Nile Valley and N Sudan (Happold 1967b).

Habitat These gerbils live in a variety of habitats. In Morocco, recorded in fields, coastal dunes, palm groves and amongst rocks (collectors' field notes). In Algeria, they have been found in fields, other open habitats and rocky hills (e.g. Hoggar), but not in forests or extensive sandy regions. In Libya, known from oases, mainly in mesic sedge habitats, tamarisk and acacia vegetation on edge of oases; also in cliffs, rocky outcrops and talus (Ranck 1968). In Egypt, recorded among limestone cliffs near the sea, temple ruins, vegetated rocky slopes, dunes, boulder habitats, palm groves and barley fields, and often found in mud and stone houses (Osborn & Helmy 1980). In general, these gerbils prefer habitats associated with rocks and vegetation rather than non-vegetated sand.

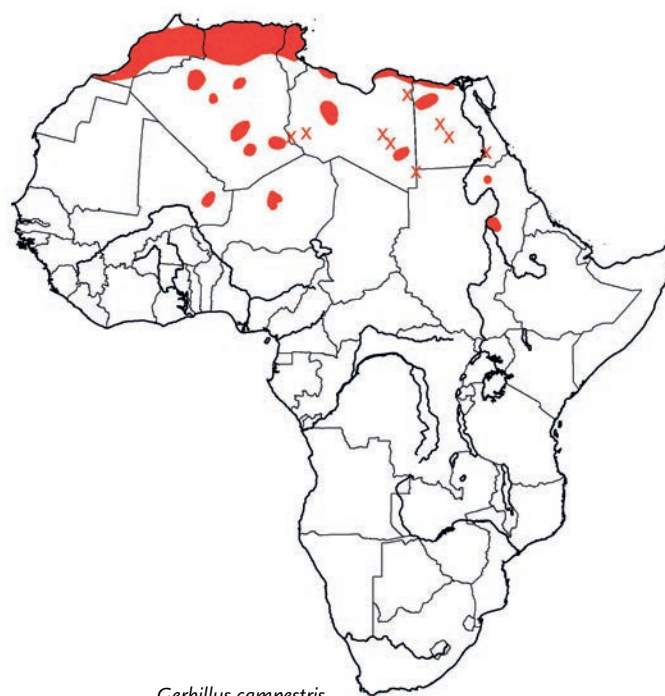

Abundance Considered 'the most widely distributed of all Libyan rodents' (Ranck 1968) and 'easily trapped in all habitats' in Egypt (Osborn & Helmy 1980). In N Sudan, considered uncommon and found only in two localities, both rocky jebels, where *Acomys cahirinus* was five times as numerous as *G. campestris* (Happold 1967b).

Adaptations Nocturnal and terrestrial. Digs burrows in sandy habitats; lives in crevices in rocky habitats.

Foraging and Food No information.

Social and Reproductive Behaviour In Egypt, occurs in sandy habitats with *G. gerbillus* and *G. andersoni*, amongst cliffs and rocky areas with *Acomys cahirinus* and *Eliomys melanurus*, and in salt marshes with *Psammomys obesus*, *G. amoenus*, *G. simoni* and *G. henleyi* (Osborn & Helmy 1980).

Reproduction and Population Structure Duration and timing of reproductive season varies according to locality and climate. Reproduction in coastal desert populations in Egypt occurs during winter rains (Nov–Apr), but inland populations may breed later (Osborn & Helmy 1980). In N Sudan, reproduction probably occurs in Sep–Nov, after the end of the short wet season when temperatures are declining. Lactating ♀♀ in Morocco in Aug. Litter-size: 5 (3–6, $n = 3$; Egypt).

Gerbillus campestris

Predators, Parasites and Diseases Remains of this species have been found in owl pellets throughout Algeria (Kowalski & Rzebik-Kowalska 1991). Four species of fleas have been found on individuals and in nests; infection rates at two localities in Egypt were 10% and 20% ($n = 30, 15$) (Hoogstraal & Traub 1965a).

Conservation IUCN Category: Least Concern.

This common widespread species is not threatened.

Gerbillus cosensi COSENS'S GERBIL

Fr. Gerbille de Cosens; Ger. Cosens Rennmaus

Gerbillus cosensi Dollman, 1914. Abstr. Proc. Zool. Soc. Lond. 1914 (131): 25. Ngamatak, Turkwel Valley, Kenya.

Taxonomy Petter (1975a) considered *cosensi* to be a subspecies of *G. agag*, within the subgenus *Gerbillus*, with the suggestion that it could be a valid species. Lay (1983) and Musser & Carleton (1993) considered *cosensi* to be a valid species but Musser & Carleton (2005) treat *cosensi* as a synonym of *G. agag* (which is here regarded as *incertae sedis*). Synonyms: none. Chromosome number: not known.

Description Small pale gerbil. Dorsal pelage pale sandy-brown. Dorsal hairs grey at base with sandy-brown terminal band, black tip on some hairs in mid-dorsal line. Flanks paler. Ventral pelage pure white, poorly delineated from flanks. Crown of head and nose sandy-brown. Cheeks, chin and throat white. Supraorbital and postauricular white patches. Fore- and hindlimbs and feet white. Soles of hindfeet hairy. Tail long (ca. 125% of HB), slightly bicoloured, sandy above, white below; covered with short bristles; longer black and white hairs on terminal end form narrow pencil.

Geographic Variation None recorded.

Similar Species

G. harwoodi. Smaller in all measurements; dorsal pelage glossy, orange-brown to dark orange-brown; postorbital patch absent; postauricular patch present; hindfeet naked; tail with well-developed pencil; distribution disjunct in N Kenya.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Known only from five localities in NW Kenya: Ngamatak (type locality), Kangatet, Lodwar, Lokori and Archer's Post.

Habitat Dry semi-arid country. Two specimens obtained in 'Sporobolus grass plains' at Archer's Post.

Abundance Rare; known only from a very few specimens.

Remarks 'Burrows in sand' (label, BMNH). 'Lives in sand dunes; covers entrance of hole in daytime' (collector's label; NMK).

Conservation IUCN Category: Data Deficient.

Gerbillus dasyurus WAGNER'S GERBIL

Fr. Gerbille de Wagner; Ger. Wagners Rennmaus

Gerbillus dasyurus (Wagner, 1842). Arch. Naturgesch. 8: 20. Sinai, Egypt.

Taxonomy Originally described in the genus *Dipodillus*, and also placed in the genus *Dipodillus* by Musser & Carleton (2005). Synonyms (all extralimital to Africa): *dasyroides*, *gallagheri*, *leosollicitus*, *palmyrae*. Subspecies: none. Chromosome number: 2n = 60, FN = 69 and 70

(Egypt; other FN numbers in Middle East, see Wassif *et al.* 1969 in Harrison & Bates 1991).

Description Graceful small pale-coloured rodent with long well-haired tail. Pelage long and dense. Dorsal pelage sandy-buff, inconspicuously speckled with black; hairs grey at base, subterminal band sandy-buff, usually black at tip. Flanks paler with clear yellowish band on lower flanks (without blackish speckling). Dorsal pelage varies in colour geographically. Ventral pelage pure white. Head similar in colour to dorsal pelage. Line of black-tipped hairs from base of eye to base of ear. Supraorbital and supraauricular patches white, sometimes indistinct. Eyes large, dark. Ears greyish-fawn, with fringe of small white hairs. Chin, throat and chest white. Fore- and hindlimbs white. Soles of hindfeet darkly pigmented, naked. Tail long (122–155% of HB, % very variable), bicoloured, sandy-buff above, white below; well covered with short hairs at base, well-defined pencil on terminal half ending in small tuft. Skull: upper incisors each with single groove, auditory bullae inflated. Nipples: not known.

Geographic Variation Pelage colour varies according to substrate and environment (Harrison & Bates 1991). Individuals in Egypt are paler than some subspecies in the Middle East.

Similar Species

G. mackilligini. Very similar, HB on average shorter; tail long with well-developed pencil; larger auditory bullae; upper incisors grooved; SW Egypt and NE Sudan.

G. campestris. HB longer; tail with well-developed pencil; auditory bullae inflated; upper incisors grooved; in Egypt, only west of Nile R.

Sekeetamys calurus. HB longer; tail black, bushy with white tip; auditory bullae inflated; incisors ungrooved; Eastern Desert of Egypt and Sinai.

Distribution Sahara Arid BZ. Recorded in NE Egypt between the Nile R. and the Red Sea (between 29° N and 30° N), and in Sinai,

at 0–2000 m. Extralimittally in countries of the Arabian peninsula, Israel, Lebanon, Jordan, Iraq and Syria.

Habitat Crevices and rock shelves in sandstone and limestone cliffs, boulder-strewn wadis and in sandy areas beneath *Nitraria* bushes on coast (Sinai). Recorded in similar habitats in other countries, as well as in thorny thickets and salt flats. Syntopic with *Sekeetamys calurus*, *Acomys cahirinus*, *A. russatus* and *Eliomys quercinus* (Osborn & Helmy 1980).

Abundance No information for Egypt. In SW Saudi Arabia, population numbers varied at three study localities, and fluctuated by a magnitude of 2–3 during the course of a year. Minimum and maximum numbers were 5.19–13.92, 3.03–9.07 and 4.48–10.7 individuals/ha (Al-Khalili & Delany 1986). Very common in Israel (Qumsiyeh 1996).

Adaptations Nocturnal and terrestrial. Individuals in rocky habitats live in rock crevices and under boulders during the day. In sandy areas, they hide in burrows 15–20 cm below the surface, with the entrances plugged with sand.

Foraging and Food Herbivorous. In captivity, individuals feed on foliage of *Zygophyllum coccineum*, raw carrots and dry bread, but they do not eat insects (Osborn & Helmy 1980). In Saudi Arabia, feeds on seeds of annual herbs (Harrison & Bates 1991).

Social and Reproductive Behaviour Social. In captivity, individuals mark their territory by 'ceremonial digging', drumming with the hindfeet and by rubbing secretions from the mid-ventral gland on the substrate (Fiedler 1973). Usually only the ♀♀ look after the young.

Reproduction and Population Structure In Egypt, captive individuals bred from Oct–Jun; litter-size 2–6 (Flower 1932). In SW Saudi Arabia (Al-Khalili & Delany 1986), reproduction only during wettest period of year (Feb–May). Gestation: 24–26 days. Embryo number in wild: 5.12 (4–6, n = 27). Litter-size in captivity: 4.8 (3–6, mode 5 and 6, n = 6). At birth, mean weight = 1.68 g, young altricial, naked. Development comparatively slow: hair pigmentation visible Day 5; upper incisors erupt Day 15; ears open Day 19; eyes open Day 22; weaned Day 40; weight 14–15 g Day 70. Probably do not breed in year of birth. Ontogeny described in detail by Fiedler (1973).

Predators, Parasites and Diseases Ectoparasites include four species of fleas, *Xenopsylla dipodilli*, *X. nubica*, *X. conformis* and *Synosternus cleopatrae* (Egypt; Hoogstraal & Traub 1965a).

Conservation IUCN Category: Least Concern.

Gerbillus dunni DUNN'S GERBIL

Fr. Gerbille de Dunn; Ger. Dunns Rennmaus

Gerbillus dunni Thomas, 1904. Ann. Mag. Nat. Hist., ser. 7, 14: 101. Gerlogobi, E Ethiopia. (Original description placed Gerlogobi in 'Somalia'.)

Taxonomy Petter (1975a), Lay (1983) and Musser & Carleton (1993) treat *dunni* as a valid species, but Cockrum (1977) considers it to be conspecific with *latastei*. Yalden *et al.* (1976) place *dunni* as a synonym of *G. pyramidum*. However, the geographic ranges of *latastei* and *pyramidum* are far from that of *dunni*. The type locality is in E Ethiopia, not in Somalia as recorded by Thomas. Synonyms: none. Chromosome number: 2n = 74 (Capanna & Merani 1981).

Description Small pale-coloured gerbil, with hairy soles and long tail. Dorsal pelage sandy-brown; hairs light grey at base, sandy-brown on terminal third, often with black tip. Hairs soft. Flanks paler, hairs white at base. Ventral pelage pure white, not sharply defined from flanks. Crown of head and nose similar to back, but darker and blacker. Chin and throat white. Supraorbital and postauricular patches inconspicuous or not present. Upper surfaces of hindlimbs sandy-fawn, inner surfaces white; feet white. Soles of hindfeet hairy (although maybe naked close to 'heel'). Tail long (ca. 137% of HB), grizzled sandy-brown above, white below; terminal pencil small and inconspicuous.

Geographic Variation None recorded.

Similar Species

G. pulvinatus. Similar in general size; soles hairy; auditory bullae larger.

G. pusillus. Smaller (HB: 65–77 mm, T: 110–115 mm); dorsal pelage darker; white ventral pelage sharply defined; soles naked.

Microdillus peeli. Smaller (HB: 66–82 mm); tail short (50–65 mm); soles naked.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Known only from a few localities in E Ethiopia, Eritrea and Somalia. May occur in Djibouti (see Pearch *et al.* 2001).

Habitat Specimens have been obtained on the steppe and dry savanna habitats near the coast of Somalia (Capanna & Merani 1981).

Abundance Few specimens; rare or uncommon (?).

Remarks Juveniles found in Dec.

Conservation IUCN Category: Data Deficient.

Gerbillus floweri FLOWER'S GERBIL

Fr. Gerbille de Flower; Ger. Flowers Rennmaus

Gerbillus floweri Thomas, 1919. Ann. Mag. Nat. Hist., ser. 9, 3: 559. Wadi Hareidin, 22.4 km south of Al Arish, Sinai, Egypt.

Taxonomy Considered by Lay (1983) as a potentially valid species, which may encompass at least part of the great chromosomal variability found near the type locality, with $2n$ ranging from 51 to 66 (near Gaza and in the Gaza strip; Wahrman & Gourewitz 1973). Retained here, as the name *G. floweri* has priority over *G. bonhotei* described from the same locality by Thomas (1919). Synonyms: none. Chromosome number: not known.

Description Small to medium-sized gerbil. Dorsal pelage pale cinnamon to tawny, with indistinct dorsal stripe; hairs grey at base, sandy-buff at tip. White patch on rump. Ventral pelage pure white. Prominent preorbital, postorbital and postauricular white spots. Nasal region white. Feet pure white. Soles of hindfeet hairy. Tail long (120–130% of HB), usually without brownish or blackish hairs dorsally and with a relatively inconspicuous fuscus pencil.

Geographic Variation None recorded in Africa.

Similar Species

G. pyramidum. Darker with more distinct dorsal stripe; mastoid portion of the auditory bullae less inflated; chromosome number: $2n = 38$; Egypt, Sudan and westwards to N Mali.

G. tarabuli. Smaller; chromosome number: $2n = 40$; only west of Libya.

G. gerbillus. Smaller; chromosome number: $2n = 42/43$; distributed throughout the whole Sahara.

Distribution Sahara Arid BZ. Recorded from Egypt in northern Sinai and the Eastern Desert; southern limit Wadi Wardan (Osborn & Helmy 1980). Extralimittally known from the Negev, and from the coastal plains of Israel and Palestine (Harrison & Bates 1991).

Habitat Palm groves, near cultivation, in wadis and sandy dunes (Osborn & Helmy 1980).

Abundance May live in dense populations in sand dunes of Sinai (Wahrman & Gourewitz 1973).

Remarks Nocturnal and terrestrial. Digs extensive burrows in loose sand, with small entrance holes plugged with sand (Wassif 1953, in Harrison & Bates 1991). Camel dung and seeds of *Citrullus colocynthis* found in burrows, and assumed to be part of the diet (Wassif 1953, in Harrison & Bates 1991).

*Gerbillus floweri*

Conservation IUCN Category: Least Concern.

Gerbillus gerbillus LESSER EGYPTIAN GERBIL (SMALL EGYPTIAN GERBIL)

Fr. Petite Gerbille des sables; Ger. Kleine Rennmaus

Gerbillus gerbillus (Olivier, 1801). Bull. Sci. Soc. Philom. Paris 2: 121. Giza Province, Egypt.

Taxonomy Originally described in the genus *Dipus*. Synonyms: *aegyptius*, *aeruginosus*, *asyutensis*, *discolor*, *foleyi*, *hirtipes*, *longicaudatus*, *psammophilous*, *sudanensis*. See Musser & Carleton (2005) for further comment. Subspecies: none. Chromosome number: $2n = 42$ (♀ ♀), $2n = 43$ (♂ ♂) (Qumsiyeh & Schlitter 1991).

Description Small gerbil. Dorsal pelage relatively long and soft, sandy in colour; hairs grey at base, yellowish to orange terminally or subterminally, with a minute dark tip in some individuals. White rump patch just above base of tail. Flanks paler, hairs with a white zone between grey base and sandy tip. Ventral pelage pure white, more or less well delineated from the flanks. Head with supraorbital and postauricular white patches. Ears relatively large and covered with short hairs. Eyes large. Fore- and hindfeet white; hindfeet long with narrow tarsus and long digits, covered with hairs of variable length, including some that may be very long. Tail long (ca. 130% of HB), bicoloured, sandy above and whitish below, with usually a long pencil of whitish to dark grey hairs. Mastoid portion of auditory bullae very inflated. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded in Africa.

Similar Species

G. pyramidum. Larger on average; darker pelage; more robust hindfeet; chromosome number: $2n = 38$; present along the Nile Valley and in southern Sahara from Chad to Mali.

G. tarabuli. Larger on average; darker pelage; more robust hindfeet; chromosome number: $2n = 40$; widespread in desert to semi-desert regions of North Africa.

G. nigeriae. Similar size; usually darker; wider and less-hairy hindfeet; chromosome number: $2n = 62-74$; northern part of Sahel savannas from Mauritania to Chad.

Distribution Sahara Arid BZ. Widespread in desert and semi-desert regions of North Africa, from Mauritania to Egypt, south to N Mali, Niger and Chad. Extraliminally present in Sinai and S Israel (Harrison & Bates 1991).

Habitat In coastal Mauritania, found on shifting sand, either in dune or inter-dune habitats with sparse plant cover and, to a lesser extent, around temporary settlements of nomadic cattle pastoralists (Klein *et al.* 1975, Granjon *et al.* 1997a). In Egypt, found in dunes, sand patches in palm groves and cultivated areas, patches of windblown sand in wadis, and oases (Osborn & Helmy 1980). In Algeria, also found on shifting sand in dunes, oases or even wadis (Petter 1961, Kowalski & Rzebiak-Kowalska 1991). Shows strong preference for sandy habitats.

Abundance Common in suitable habitats. In coastal Mauritania, densities range from 0.2 to 4.8 individuals/ha during the course of the year (Klein *et al.* 1975); capture rates of 3.5–8 individuals/100

*Gerbillus gerbillus*

trap-nights recorded in favourable habitats in March 1995 (Granjon *et al.* 1997).

Adaptations Terrestrial and nocturnal. Burrows are 30–80 cm deep, and may be plugged with sand during the warm season (Osborn & Helmy 1980). Said to experience lethargy in the laboratory, an observation linked to its seasonal apparent disappearance from the field in Morocco (Saint Girons & Petter 1965). Homing behaviour was observed in ca. 50% of the individuals released 1000 m away from their burrows ($n = 40$) and 20% of those released 2000 m away ($n = 40$; Mermoud 1970).

Foraging and Food Predominantly granivorous at all seasons in Israel. Foods also include plant material (*Thynalea* sp., *Erodium* sp. and *Plantago* sp., especially in winter) and insects (especially in spring) (Bar *et al.* 1984).

Social and Reproductive Behaviour In Mauritania, home-range is large (diameter up to 100 m) and shifting (especially for ♂ ♂). Nocturnal movements potentially very important, associated with exploratory behaviour in search of food (Klein *et al.* 1975). Mean distance between successive captures was 10.7 m, and maximum distance between recaptures was 105 m, over a 4-day trapping period in March 1995 (Cosson *et al.* 1997).

Reproduction and Population Structure In NW Mauritania, reproduction is nearly continuous, with reduced rate in Jan and Feb. Mean monthly embryo number: 3.4–6.0 depending on time of year.

Maximal birth rates and minimal death rates recorded in the wet season with long daylength (Jul–Oct), followed by a major phase of population expansion in the cool dry season (Nov–Jan) (Klein *et al.* 1975). Reproductive activity said to be related to temperature and daylength, and fecundity to resource availability (Klein *et al.* 1975). In Egypt, reproduction from Jan–May; litter-size: 4.3 (3–6), $n = 7$; (Osborn & Helmy 1980).

Predators, Parasites and Diseases Predators include Sand Foxes *Vulpus pallida*, Barn Owls *Tyto alba* and *Cerastes* snakes (Klein *et al.* 1975, Granjon *et al.* 2002b). Ticks (*Hyalomma dromedarii* and *H. impeltatum*) and fleas (*Synosternus cleopatrae*) are often found on these gerbils; the fleas occasionally carry plague (Klein *et al.* 1975).

Conservation IUCN Category: Least Concern.

Gerbillus harwoodi HARWOOD'S GERBIL

Fr. Gerbille de Harwood; Ger. Harwoods Rennmaus

Gerbillus harwoodi Thomas, 1901. Ann. Mag. Nat. Hist., ser. 7, 8: 275. L. Naivasha, Kenya.

Taxonomy Yalden *et al.* (1976) include *harwoodi* within *G. ruberrimus*; all other authors (Petter 1975a; Lay 1983; Musser & Carleton 1993) regard *harwoodi* as a valid species. The smaller size of *harwoodi*, its distinctive darker colouration and limited range in Kenya and Tanzania suggest that it is separable from other named forms. The form *luteus*, originally considered a full species, is probably a synonym of *harwoodi* (Petter 1975a, Musser & Carleton 1993). Referred to as *Dipodillus harwoodi* by Musser & Carleton (2005). Synonyms: *luteus*. Subspecies: none. Chromosome number: not known.

Description Very small gerbil, with orange-brown or sandy-brown back, and long tail. Dorsal pelage glossy, orange-brown to dark orange-brown; hairs dark grey at base, sandy-brown or orange-brown terminally, often with black tip. Flanks similar to back. Ventral pelage pure white, sharply delineated. Dorsal and ventral pelage long and soft. Head and nose similar to back; cheeks sandy-brown; postorbital patches absent. Postauricular patches present. Fore- and hindfeet white. Soles of hindfeet naked. Tail long (ca. 126% of HB), dark orange-brown above, paler below. Long dark hairs on terminal third form well-developed pencil. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Gerbillus cosensi. Larger (HB: 90–135 mm, T: 100–143 mm); dorsal pelage pale sandy-brown; white of ventral pelage merges into colour of flanks; soles of hindfeet hairy.

G. percivali. Similar in size; dorsal pelage dark rusty-brown; white of ventral pelage clearly delineated from colour of flanks; hairs usually long and soft; soles of hindfeet naked; prefers drier environments.

Gerbillus harwoodi

G. pusillus. Similar in size and colour; white of ventral pelage clearly delineated from colour of flanks; hairs long and soft; soles of hindfeet naked; drier habitats of C and S Kenya.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ and Afromontane–Afroalpine BZ. Limited distribution in the highlands and Rift Valley of C Kenya, as well as drier areas towards the coast (*harwoodi*), and N–C Tanzania (*luteus*).

Habitat Little information. Locality records suggest grasslands in *Acacia* savanna. Found on open plains to the west of L. Natron at night (specimen label, NMK).

Abundance 'Plentiful' (L. Naivasha in 1912 [specimen label BMNH]), but distribution evidently very restricted.

Remarks Nocturnal. Lives in deep burrows on grassy plains during daytime (collector's notes, NMK). Pregnant ♀ with four embryos in Jun at Nanyuki, Kenya (Southern & Hook 1963).

Conservation IUCN Category: Least Concern.

Gerbillus henleyi HENLEY'S GERBIL

Fr. Gerbille de Henley; Ger. Henleys Rennmaus

Gerbillus henleyi (de Winton, 1903). Novit. Zool. 10: 284. Zaghigh, Wadi Natron, Egypt.

Taxonomy Originally described in the genus *Dipodillus*. Synonyms: *jordani*, *makrami*, *mariae*. Subspecies: none. Chromosome number: 2n = 52, aFN = 58–62 (Volobouev *et al.* 1995).

Description Very small, delicate gerbil. Dorsal pelage sandy to ashy-beige, sometimes becoming more russet on the flanks; hairs brownish-grey at base, with subterminal band of sandy-buff, grey-black tip (some hairs with grey-black subterminal band and sandy-buff tip). White rump patch prominent in specimens from Egypt, less so in specimens from West Africa. Ventral pelage pure white, clearly delineated along the cheeks and flanks. Head with supraorbital and postauricular white (or pale) patches. Fore- and hindfeet white; hindfeet delicate and naked. Tail slender, long (ca. 130% of HB), with a thin pencil of more or less dark hairs. Nipples: 2 + 2 = 8.

Geographic Variation None recorded in Africa.

Similar Species

G. nanus. On average larger with a relatively longer tail; chromosome number: 2n = 52, aFN = 58–62; sympatric in western part of range.

G. campestris. Larger; chromosome number: 2n = 56–58; sympatric in most of the range (except the SW part).

G. nigeriae. Larger, soles of hindfoot hairy; chromosome number: 2n = 62–74; sympatric south of Sahara.

G. gerbillus. Larger, soles of hindfoot hairy; chromosome number: 2n = 42–43; sympatric in most of the range.

G. nancillus. On average smaller; chromosome number: 2n = 56; sympatric south of Sahara.

Distribution Sahara Arid BZ (northern and southern fringes) and Sahel Savanna BZ. Widespread in desert to semi-desert regions of North Africa. Recorded from Morocco to Egypt, and from N Senegal westwards to Mali, Burkina, Niger, Chad and N Sudan (Musser &

Gerbillus henleyi

Carleton 1993, Dobigny *et al.* 2002b, L. Granjon unpubl.). Presence in N Burkina and N Senegal is interpreted as a possible southward extension of the range following desertification (Maddalena *et al.* 1988, Duplantier *et al.* 1991). Extraliminally present in the Arabian Peninsula and the Middle East.

Habitat Sandy areas, gravel plains, salt marshes, wadis and crop fields (review in Shenbrot *et al.* 1994). In C Negev (Israel), more abundant on gravel plains and in dry river beds on various substrates than in sandy habitats (Shenbrot *et al.* 1994).

Abundance Quantitative data lacking in Africa, but may prove to be locally more abundant than usually thought. Abundant in pellets of Barn Owls *Tyto alba* from the Senegal River Valley (L. Granjon unpubl.). Average densities ranged from 0.9 to 2.3 individuals/ha (range 0–5.5/ha) in four habitats in Israel (Shenbrot *et al.* 1994).

Adaptations Terrestrial and nocturnal. Burrows are shallow and narrow (Petter 1961, Harrison & Bates 1991). Moulting observed in early autumn (Sep–Oct) in Israel (Shenbrot *et al.* 1994).

Foraging and Food Mainly granivorous, but also herbivorous to some extent. In captivity, found to depend heavily on seeds, the husks of which are removed before eating to maximize energy intake. Individuals lost weight when provided only with fresh vegetation. Stems of *Atriplex halimus* and *Moricandia nitens* were preferred plants when offered a selection of green plants (Negev Desert, Israel; Khokhlova *et al.* 1995, Kam *et al.* 1997).

Social and Reproductive Behaviour Limited rates of recapture of individuals suggest regular changes of home-range in Israel (Shenbrot *et al.* 1994).

Reproduction and Population Structure In the Negev, reproductively active adults present from Feb to Oct. Young individuals present in population in low numbers (7–26%) in all months except Sep (76%) (Shenbrot *et al.* 1994). Embryo number: 3 (Jul; Senegal; K. Bâ unpubl.), 4 and 6 (Jun; Arabian Peninsula; Harrison & Bates 1991). Maximum recorded longevity of 241 days in the wild

(Shenbrot *et al.* 1994) and more than three years in captivity (Petter 1961).

Predators, Parasites and Diseases Predators include owls, especially the Barn Owl (Kowalski & Rzebik-Kowalska 1991). Represented only 3% of the prey of Barn Owls in N Senegal (Bâ *et al.* 2000). In Israel, infestation by non-specific species of fleas is low (Shenbrot *et al.* 1994).

Conservation IUCN Category: Least Concern.

Gerbillus hesperinus MOROCCAN GERBIL

Fr. Gerbille de Maroc; Ger. Marokkanisch Rennmaus

Gerbillus hesperinus Cabrera, 1936. Bol. Real. Soc. Esp. Hist. Nat., p. 365. Mogador (= Essaouira), Morocco.

Taxonomy Lay (1975, 1983) and Musser & Carleton (1993, 2005) regard *hesperinus* as a valid species. In contrast, Petter (1975a) considered *G. hesperinus* to be a synonym of *G. pyramidum*. Synonyms: none. Chromosome number: 2n = 58, FN = 76 (Lay 1975) (cf. *G. pyramidum*).

Description Small gerbil with long soft pelage. Dorsal pelage dark sandy-brown, hairs dark grey at base with sandy-brown tips; flanks cinnamon. Ventral pelage pure white, clearly delineated from colour of flanks. Chin, throat, fore- and hindlimbs white. Soles of feet hairy. Tail long (ca. 115% of HB), cinnamon above, white below; longer hairs form slight pencil at terminal end.

Geographic Variation None recorded.

Similar Species In Morocco:

G. hoogstraali. Similar HB; longer ear; chromosome number: 2n = 72; very restricted distribution.

G. gerbillus. HB on average smaller; longer tail; white rump patch; GLS smaller; chromosome number: 2n = 42/42; widespread.

G. tarabuli. Similar HB; much longer tail; chromosome number: 2n = 40; widespread.

Gerbillus hesperinus

Distribution Endemic to Africa. Mediterranean Coastal BZ. Recorded only from near Essaouira on the coast of Morocco, north of the Middle Atlas mountains (Lay 1983).

Habitat Coastal sand dunes (Aulagnier & Thévenot 1986).

Abundance Probably rare; known only from a few specimens.

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

The limited geographic distribution and fragmentation of sand dunes are cause for concern.

Measurements

Gerbillus hoogstraali HOOGSTRAAL'S GERBIL

Fr. Gerbille de Hoogstraal; Ger. Hoogstraals Rennmaus

Gerbillus hoogstraali Lay, 1975. Fieldiana Zool. 65: 90. 7 km south of Taroudannt, Morocco.

Taxonomy Distinguished from its closely related congeners by skull characters and karyology. This species is one of several allopatric species (*G. hesperinus*, *G. occidus*, *G. riggenbachi*), each of which has a very small geographic range on the coast of Morocco. Synonyms: none. Chromosome number: 2n = 72, FN = 80 (Lay 1975).

Description Small gerbil. Dorsal pelage sandy-brown; dorsal hairs medium grey with sandy-brown at tip, and sometimes with black terminal rings. Flanks paler than dorsal pelage and tending towards orange-brown. Ventral pelage pure white, clearly delineated from flanks. Head similar to dorsal pelage. Ears pale, with brownish band on outer margin. Slight ring of dark hairs around eye. Small postorbital spot in some individuals. White postauricular spot. Lower cheeks, chin, throat and chest white. Fore- and hindlimbs and feet with short dense white hairs. Soles of HF hairy. Tail long (ca. 120% of HB), bicoloured with short dense hairs; sandy-brown above, cream or white below; hairs longer and denser towards tip forming small pencil. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. campestris. Slightly larger; tail longer and relatively longer with well-developed pencil; soles of hindfoot naked; smaller auditory bullae; also occurs near Agadir.

Distribution Endemic to Africa. Mediterranean Coastal BZ. Recorded only in Morocco, from a few localities in the Sous Valley near Agadir and near Taroudannt. The distribution is restricted to the

Gerbillus hoogstraali

narrow Sous Valley, bordered by the High Atlas to the north and the Anti Atlas to the south.

Habitat Hard-packed sandy clay covered with fine red sand, alternating with low sand dunes. Vegetation sparse, mainly scattered thorny *Ziziphus* shrubs.

Abundance No information; known only from a few individuals. At the type locality, specimens were collected over an area of about 7 km by 7 km.

Remarks Terrestrial and nocturnal. Appears to be a typical arid-adapted gerbil. Burrow entrances are located at the bases of *Ziziphus* shrubs. One ♀ trapped in July contained six placental scars, and two subadults trapped at the same time, suggest that reproduction occurs during late spring and early summer (Apr–Jul). Duration of reproductive activity not known.

Conservation IUCN Category: Vulnerable.

The limited geographic distribution and fragmentation of sand dunes are cause for concern.

Gerbillus juliani JULIAN'S GERBIL

Fr. Gerbille de Julian; Ger. Julians Rennmaus

Gerbillus juliani (St Leger, 1935). Ann. Mag. Nat. Hist., ser. 10, 15: 669. Bulhar, Somalia.

Taxonomy Originally described in the genus *Dipodillus* and later placed in the genus *Monodia* by Roche & Petter (1968). Petter (1975a) allocated *juliani* to the genus *Gerbillus*, but regarded it as synonymous with *G. watersi* without supporting evidence. Musser & Carleton (1993), following Lay (1983), consider *G. juliani* as a valid species pending revision of the genus (a decision retained here), but Musser & Carleton (2005) place *juliani* as a synonym of *G. watersi*. Synonyms: none. Chromosome number: not known.

Description Very small gerbil. Dorsal pelage sandy-fawn; hairs steel-grey at base with sandy-fawn tips. Pelage on flanks brighter

than on back. Ventral pelage pure white. Head sandy-fawn; cheeks white, with thin sandy-fawn line below each eye. Supraorbital and postauricular white patches. Fore- and hindlimbs white, feet white. Tail very long (ca. 150% of HB), sandy-fawn above, white below, with pencil of long brown hairs at terminal end. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. brockmani. Larger (HB: 71–84 mm).

G. somalicus. Larger (HB: 82–90 mm).

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from only four localities in Somalia (Roche & Petter 1968); not recorded from arid regions in neighbouring Ethiopia.

Habitat Semi-arid habitats. One specimen from Bulhar ‘trapped on maritime plain near the town’. Other specimens captured in abandoned cultivation near the Webi Shabeelle river, in ‘bush’ and in ‘wooded steppe’ (Roche & Petter 1968).

Abundance ‘Must be rare, as it appears to be the only [specimens] I caught with numbers of *G. acticola* which was relatively common’ (R. E. Drake-Brockman, in St Leger 1935).

Remarks Little information. Presumably nocturnal, living in burrows during daytime. Apparently lives ‘alongside and fraternising with *G. acticola*’ (R. E. Drake-Brockman, in St Leger 1935).

Conservation IUCN Category: Least Concern.

Lack of specimens (especially in recent years) suggests that ‘Data Deficient’ is a more realistic assessment.

***Gerbillus latastei* LATASTE'S GERBIL**

Fr. Gerbille de Lataste; Ger. Latastes Rennmaus

Gerbillus latastei Thomas and Trouessart, 1903. Bull. Soc. Zool. France 28: 172. Kebili, Tunisia.

Taxonomy The definition of this hairy-footed gerbil species is controversial. Cockrum (1977) lists nine forms which he considers may be conspecific, five of which (*bonhotei*, *dunni*, *perpallidus*, *riggenbachi*, *rosalinda*) are considered as separate species by Lay (1983) pending revision. Ranck (1968) refers to *latastei* as a subspecies of *Gerbillus gerbillus*. Here, following Lay (1983) and Musser & Carleton (1993, 2005), *G. latastei* is considered as a valid species restricted to Tunisia and Libya. Synonyms: *aureus*, *favillus*, *nalutensis*. Subspecies: none. Chromosome number: 2n = 74, FN = 92–100 (as *aureus*; Jordan *et al.* 1974); specimens labelled *G. latastei* (in MNHN) have 2n = 74 and 75.

Description Small orange and white gerbil with long tail. Dorsal pelage bright orange; dorsal hairs grey at base with orange tip. Flanks whitish-orange; hairs white at base, orange at tip. Colour of flanks merges gradually into pure white of ventral pelage. Crown of head orange. Supraorbital, postorbital and postauricular white patches. Cheeks, nose, chin, throat, fore- and hindlimbs and feet white. Soles of hindfeet hairy. Tail long (ca. 116% of HB), sandy or sandy-orange above, sandy-orange or white below; darker hairs form narrow pencil at terminal end of tail.

Geographic Variation None recorded.

Similar Species

G. gerbillus. Smaller HB; shorter ear; white rump patch; chromosome number: 2n = 42/43; widespread.

G. tarabuli. Similar HB; longer tail; chromosome number: 2n = 40; widespread.

Distribution Endemic to Africa. Mediterranean Coastal BZ and Sahara Arid BZ. Recorded only from Tunisia and W Libya.

Habitat Slopes of sparsely vegetated hamadas, and on the margins of small wadis (Libya; Ranck 1968). In Tunisia, found in sand of dry river beds.

Abundance Probably rare or uncommon.

Remarks Apparently no other information available.

*Gerbillus latastei*

***Gerbillus lowei* LOWE'S GERBIL**

Fr. Gerbille de Jebel Marra; Ger. Lowes Rennmaus

Gerbillus lowei (Thomas and Hinton, 1923). Proc. Zool. Soc. Lond. 1923: 261. Jebel Marra, Sudan. (Exact locality not recorded.)

Taxonomy Originally described in the genus *Dipodillus*. Regarded as a valid species by Lay (1983) and Musser & Carleton (1993). The limited geographical range, and isolation from other populations of *G. campestris*, suggest that *lowei* is not a subspecies of *G. campestris* as given by Petter (1975a). Thomas & Hinton (1923a), when describing the holotype as *Dipodillus lowei*, referred to it as 'a dark mountain form of the *D. campestris* group'. Musser & Carleton (2005) refer to this species as *Dipodillus lowei*. Synonyms: none. Chromosome number: not known.

Description Small, long-haired gerbil with long well-haired tail. Dorsal hairs 11–15 mm. Dorsal pelage dark brown; hairs dark grey at base, dark brown or chestnut at terminal end, often with black tip. Flanks paler, chestnut or cinnamon merging into pure white of ventral pelage. Crown of head and nose similar to dorsal pelage. Chin, throat white. Postorbital and postauricular white patches. Soles of hindfeet naked. Tail very long (ca. 140% of HB), dark brown above with short black-tipped hairs, paler below; terminal half or one-third with long soft dark hairs forming conspicuous pencil. Young animals paler than adults.

Geographic Variation None recorded.

Similar Species This species is the darkest of all gerbils and the only species of *Gerbillus* on Jebel Marra (see below).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from higher altitudes (2300–3000 m) of Jebel Marra, W Sudan. Not recorded from the dry Sahel Savanna BZ surrounding the jebel.

Habitat Lowe's Gerbils live only at the highest altitudes of Jebel Marra. They live under rocks of pumice where there is a dense cover of grasses and herbs, and among the crevices of pumice walls surrounding local vegetable gardens (Happold 1966b).

Abundance Distribution patchy; found only in selected habitats on Jebel Marra; in the single locality where most abundant, comprised 40% of rodents (total n = 15, 6 spp.; Happold 1966b).

Remarks Nocturnal and terrestrial; the very long hairs form a dense pelage, which provides insulation from the cold nights in 'winter' on Jebel Marra (minimum temperature near freezing). Diet is 'grass and flower seeds' (Lynes and Lowe, in Thomas & Hinton 1923a), as well as *Loranthus* seeds (Happold 1966b). Juveniles in several weight-classes in Nov, suggest prolonged breeding season during and after the wet season (Jul–Sep; 800 mm/year) (Happold

*Gerbillus lowei*

1966b). Small individuals (HB <85 mm) found in Nov, Dec, Mar and Apr (Lynes & Lowe specimens, BMNH).

Conservation IUCN Category: Data Deficient.

Lowe's Gerbils have a very restricted geographic range, and occur at only a few localities within their range.

Measurements*Gerbillus lowei*

HB: 104 (89–113) mm, n = 10

Gerbillus mackilligini MACKILLIGIN'S GERBIL

Fr. Gerbille de Nubie; Ger. Mackilligins Rennmaus

Gerbillus mackilligini (Thomas, 1904). Ann. Mag. Nat. Hist., ser. 7, 14: 158. Wadi Alagai, Eastern desert of Nubia, Egypt.

Taxonomy In the type description, Thomas (1904b) referred to this species as 'a very pretty pencil-tailed gerbille' in the genus *Dipodillus*. Although some authors have placed this taxon in *G. nanus*, Osborn & Helmy (1980) show that *G. mackilligini* is a valid species. Referred to as *Dipodillus mackilligini* by Osborn & Helmy (1980) and Musser & Carleton (2005). The correct spelling of the specific name is *mackilligini*, not *mackillingini* as in Musser & Carleton (1993). Synonyms: none. Chromosome number: not known.

Description Small, darkish gerbil with a very long conspicuous pencil on tail. Pelage 9–10 mm on mid-back. Dorsal pelage sandy-brown suffused with black; hairs dark grey at base, sandy-brown at terminal end, some with black tip. Ventral pelage pure white, clearly delineated from colour on flanks. Crown of head and nose similar to back. Supraorbital, postorbital and postauricular white patches. Chin and throat white. Fore- and hindlimbs white. Soles of feet pigmented, naked. White rump patch absent. Tail long (ca. 155% of HB), dark brown with small short black hairs above, sandy-brown or white below; hairs (up to 20 mm in length at tip) form very conspicuous pencil on terminal half of tail, which extends beyond end of tail. Large auditory bullae. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. gerbillus. Dorsal pelage pale orange; slightly larger (HB: ca. 90 mm, T: ca. 120 mm); soles hairy; pencil small.

G. pyramidum. Dorsal pelage bright orange-cinnamon; larger (HB: ca. 120 mm, T: ca. 150 mm); soles hairy; pencil not conspicuous.

G. henleyi. Dorsal pelage pale sandy-orange; smaller (HB: ca. 66 mm, T: ca. 90 mm); soles naked; white rump patch conspicuous; pencil small.

G. amoenus. Dorsal pelage dark; similar size, but shorter tail (ca. 106 mm); soles naked; white rump patch conspicuous; pencil small.

Distribution Endemic to Africa. Sahara Arid BZ. Recorded from the Eastern Desert of Egypt and NE Sudan.

Habitat 'Grassy patches near water' and 'bush beside water in abandoned village' in Nubia (collector's field notes). Found in burrows in a grassy valley on Jebel Elba, near the Red Sea coast, at 2500 ft (Hoogstraal 1963).

Abundance Known from only a few localities and only a few specimens. Appears to be rare (Jebel Elba; Hoogstraal 1963).

Remarks Remains of this gerbil found in owl pellets at Jebel

*Gerbillus mackilligini*

Migif, some 300 km from the nearest known living populations. Because of the current dry local climate, and the virtual lack of vegetation nearby, these pellets may have been deposited hundreds of years ago (Goodman 1986). Four individuals examined in Egypt did not have any fleas (Hoogstraal & Traub 1965a).

Conservation IUCN Category: Least Concern.

Measurements

Gerbillus mackilligini

***Gerbillus maghrebi* MAGHREB GERBIL**
Fr. Gerbille du Maghreb; Ger. Maghreb-Rennmaus

Gerbillus maghrebi Schlitter & Setzer, 1972. Proc. Biol. Soc. Washington 84: 387. 15 km WSW Taounate, Fes Prov., Morocco.

Taxonomy Placed in subgenus *Hendecapleura* by Lay (1975), and in genus *Dipodillus* by Musser & Carleton (2005). Synonyms: none. Chromosome number: unknown.

Description Small gerbil, although the largest of the North African short-tailed gerbils. Dorsal pelage pinkish-grey, purest on sides and flanks, strongly mixed with black becoming darker on forehead; hairs dark grey at base. Ventral pelage pale pinkish-buff. Head slightly darker than back. Lips pale. Colour of dorsal surface of fore- and hindfeet similar to ventral pelage. Soles of hindfeet naked. Tail long (ca. 95% of HB), slightly bicoloured, with terminal pencil. Skull large for the genus; maxilla-premaxilla junction anterior to the zygomatic plate; zygomatic arches rugged; upper toothrow relatively long; auditory bullae relatively small and well inflated ventrally. Mandible with high and large coronoid process, broad ramus and thick angular process, so that the sigmoid notch appears not to be very deep. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. campestris. Only other gerbil in the distribution range of *G. maghrebi*; on average slightly smaller; tail longer, with pencil; can be distinguished by discriminant function analysis on skull and mandibular measurements (see Aulagnier *et al.* 1993). Maxilla-premaxilla junction concealed by the zygomatic plate.

Distribution Endemic to Africa. Mediterranean Coastal BZ. Recorded only in Morocco from south of the Rif Mts, the Prérif hills and the Saïss plain to Chaouia and even Jbilets (north of Marrakech); range limited to the east by the Middle Atlas Mts (Aulagnier *et al.* 1993).

Habitat Rock and clay terrains, especially on hills and slopes with natural herbaceous vegetation. Avoids sand dunes and river beds, and has not been found in large cultivated fields, nor in densely vegetated areas, forests and matorrals.

Abundance Common in the Fes region (Prérif and Saïss) where it is locally the only gerbil (the Algerian Mouse *Mus spretus* is the main species of rodent). Less abundant in most of the range where *G. campestris* is also present. Rare south of Casablanca.

Remarks Of three ♀♀ taken in May, one contained eight embryos (three in the right horn of the uterus) (Schlitter & Setzer 1972). Main predators are Barn Owls *Tyto alba* but other owls (particularly Tawny Owls *Strix aluco*) and diurnal raptors also prey on this gerbil. In the region of Fes, formed up to 14% of diet of Barn Owls.

Gerbillus maghrebi

Conservation IUCN Category: Least Concern.

The main threat is destruction of habitat following agricultural changes (e.g. regrowth of brushwood in fields and pastures).

Measurements

Gerbillus maghrebi

***Gerbillus nancillus* SUDAN GERBIL**

Fr. Gerbille du Soudan; Ger. Sudan Rennmaus

Gerbillus nancillus Thomas and Hinton, 1923. Proc. Zool. Soc. Lond. 1923: 260. 45' N El Fasher, Plains of Darfur, Sudan.

Taxonomy Synonyms: *mauritaniae* (following Tranier & Julien-Laferrière 1990). Subspecies: none. Chromosome number: $2n = 56$, aFN = 54 (Dobigny *et al.* 2002b).

Description Very small, delicate gerbil. Dorsal pelage sandy to orangish-brown; hairs grey at base, orange-brown terminally. Paler on flanks; hairs white at base. Ventral pelage pure white, well delineated from colour of flanks. Eye-ring and postauricular patch white. Fore- and hindfeet white. Soles of hindfoot partly naked behind, with short hairs at level of the metacarpal bones. Tail long (ca. 135% of HB), bicoloured, sandy-buff above, white below, with a thin pencil of terminal hairs. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. nanus. On average larger; naked hindfeet (or nearly so); $2n = 52$; western part of North Africa.

G. henleyi. On average slightly larger; naked hindfeet; $2n = 52$; circum-Saharan distribution.

Distribution Endemic to Africa. Sahel Savanna BZ. Distribution disjunct. Described from Sudan (Thomas & Hinton 1923a), and now known to occur also in Mauritania (as *mauritaniae*), Niger and Mali (Tranier & Julien-Laferrière 1990, Dobigny *et al.* 2002b).

Habitat Sandy to sandy-clay soils with *Cenchrus biflorus*; fallow land and millet fields in Mali and Niger (L. Granjon, G. Dobigny & A. Nomao unpubl.).

Abundance No information. Apparently difficult to catch in live-traps, so may be more abundant than suspected.

Remarks One ♀ with four embryos caught in Niger (Kollo) in Jun (G. Dobigny and A. Nomao unpubl.).

Conservation IUCN Category: Data Deficient.

***Gerbillus nanus* DWARF GERBIL (BALUCHISTAN GERBIL)**

Fr. Gerbille naine; Ger. Zwerg Rennmaus

Gerbillus nanus Blanford, 1875. Ann. Mag. Nat. Hist., ser. 4, 16: 312. Gedrosia, Pakistan.

Taxonomy Lay (1983) recorded that *G. nanus* shared a number of features with *G. amoenus* (similar karyotype, naked hindfeet and accessory tympanum) and that the two species are closely related. Given their distribution, they may even prove to be conspecific; if so, *G. amoenus* would be a junior synonym of *G. nanus*. Following Petter (1961),

Rosevear (1969) and Kowalski & Rzebik-Kowalska (1991), the form *garamantis* (found by Matthey [1954] to have $2n = 54$) is considered to be synonym of *G. nanus*. Synonyms: *arabium*, *garamantis*, *hilda*, *indus*, *lixa*, *mimulus*, *quadrimaculatus*, *setonbrownnei*. Subspecies: none. Chromosome number: $2n = 52$, aFN = 58–62 (Volobouev *et al.* 1995).

Description Very small gerbil. Dorsal pelage of variable colour, from sandy to relatively dark tawny-grey; hairs grey at base, sandy to tawny at tip. Flanks paler. Ventral pelage pure white, well delineated from flanks. Head with supraorbital and postauricular white patches. Cheeks similar in colour to flanks. Fore- and hindfeet white; hindfeet small, naked or nearly so. Tail very long (ca. 140–150% of HB), with a marked pencil of pale and dark grey hairs. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

G. henleyi. Smaller on average; chromosome number: $2n = 52$, aFN = 58–62; circum-Saharan distribution.

G. nancillus. Smaller on average with a relatively smaller tail; chromosome number: $2n = 56$; northern Sahelian distribution from Mali to Sudan.

G. campestris. Larger; chromosome number: $2n = 56$ –58; all North Africa south to massifs of N Mali and Niger.

G. nigeriae. Larger on average; soles of hindfoot hairy; chromosome number: $2n = 62$ –74; northern Sahelian distribution from Mali to Chad.

G. gerbillus. Larger on average; soles of hindfoot hairy; chromosome number: $2n = 42/43$; distributed in all desert to semi-desert habitats of North Africa.

Distribution Sahara Arid and Sahel Savanna BZs. Widespread but only in western half of these BZs. Recorded from Mauritania to Tunisia south of the Atlas Mts, and south to N Mali, Niger and Chad (Lay 1983, Granjon *et al.* 1997a, Dobigny *et al.* 2002b, Granjon & Dobigny 2003 and unpubl.). Also present in the Arabian Peninsula and the Middle East to NW India.

Habitat Desert and semi-desert. Mostly found in parts of the desert with relatively deep soil and abundant vegetation, such as

wadis, oases, sebkhas edges and sandy-clay plains or basins (Petter 1961, Kowalski & Rzebik-Kowalska 1991, Granjon *et al.* 1997). In the N Sahel Savanna BZ, also common in millet fields, fallow lands, gardens and in the immediate vicinity of human dwellings (Dobigny *et al.* 2001a, b, Granjon & Dobigny 2003 and unpubl.).

Abundance Common in suitable habitats. In coastal Mauritania, capture rates of 4–6.5 individuals/100 trap-nights recorded in favourable habitats in Mar 1995 (Granjon *et al.* 1997a). It is the most numerous of gerbillids in the sandy bottom of wadis, and in oases in Algeria (Kowalski & Rzebik-Kowalska 1991). In a Saharan habitat of Morocco, 43 individuals were found on a 1 ha trapping grid (Zaïme & Pascal 1989).

Adaptations Terrestrial and nocturnal. In Algeria, uses the burrows of *Psammomys obesus* and *Meriones libycus*, as well as withdrawal cracks in dry clay soils (Petter 1961). A study of oxygen consumption and body temperature showed the species is well adapted to extreme arid areas, with a thermoneutral zone at $33 \pm 1^\circ\text{C}$ and an oxygen consumption at thermoneutrality of 50.6% of predicted value (Haim 1984).

Foraging and Food Granivorous and herbivorous. The diet is predominantly folivorous (mainly leaves of *Euphorbia calyptrata*) in the winter and spring (Feb–May), and predominantly granivorous (seeds of *Atriplex halimus* and *Salsola vermiculata*) in the summer months (Jun–Aug) (Sahara, Morocco; Zaïme & Gautier 1989).

Social and Reproductive Behaviour Found to be capable of very large movements (hundreds of metres each night) between the burrow and foraging areas in Algeria (Petter 1961). Trapping data in coastal Mauritania, showed that these gerbils display larger movements than coexisting *G. gerbillus*, *G. tarabuli* and *G. nigeriae*. Mean recapture distance 16.9 m (max 135 m) over a 4-day period (Cosson *et al.* 1997). Likewise, in Morocco, they display larger movements than coexisting *G. campestris* and *Meriones shawi*, where their mean recapture distance was 19.1 m (Zaïme & Pascal 1988).

Reproduction and Population Structure Embryo number: 2, 5 ($n = 2$; Arabia; Harrison & Bates 1991).

Predators, Parasites and Diseases Heavily preyed upon by Barn Owls *Tyto alba* in Israel (Pokines & Kerbis Peterhans 1997) as well as in Mauritania where it represented 45% of prey (Granjon *et al.* 2002b).

Conservation IUCN Category: Least Concern.

Laurent Granjon

Gerbillus nigeriae NIGERIAN GERBIL

Fr. Gerbille du Nigeriae; Ger. Nigerianische Rennmaus

Gerbillus nigeriae Thomas and Hinton, 1920. Novit. Zool., 27: 317. Farniso near Kano, Nigeria.

Taxonomy Considered to be a synonym of *G. agag* (Petter 1975a, Kock 1978b), then as a distinct species (Tranier 1975, Lay 1983). Synonyms: none. Chromosome number: $2n = 60-74$; polymorphic due to multiple Robertsonian translocations and heterochromatin variations (Tranier 1975, Volobouev *et al.* 1988, Dobigny *et al.* 2002b).

Description Small gerbil. Dorsal pelage sandy to pale ochre-orange; hairs grey at base, with sandy to ochre-orange at terminal end. Ventral pelage pure white, usually well delineated from the flanks. Head with white preorbital, postorbital and postauricular patches. Fore- and hindfeet white; soles of hindfoot covered with hairs of variable length. Long powerful tail (ca. 145% of HB) with pencil of dark hairs. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

G. pyramidum. Almost always larger; chromosome number: $2n = 38$; Mali to Egypt and Sudan.

G. tarabuli. On average slightly larger; chromosome number: $2n = 40$; only found west of Libya.

G. gerbillus. Similar size; soles of hindfoot more hairy; chromosome number: $2n = 42/43$; distributed throughout Sahara.

Distribution Endemic to Africa. Sahel Savanna BZ. Recorded from Mauritania, Mali, Burkina, Niger and Chad. Presence in these countries confirmed by chromosomal analysis (Granjon & Dobigny 2003).

Habitat Sandy areas (e.g. sand dunes, sandy veneers) and associated cultivated and fallow lands.

Abundance Large variations of abundance (0–ca. 150 ind/ha) recorded in natural habitats ('Oursi' dune, N Burkina; Sicard 1987) as well as in cultivated habitats ('Kolo' farm, Niger; Nomao & Gautun 2002). Annual cycles of abundance are biphasic (at 'Kolo') or monophasic (at 'Oursi').

Adaptations Terrestrial and nocturnal. In N Burkina, structure of burrows varies during different periods of the year: simple and superficial when individuals are dispersing; more complex, deep and filled with seeds during pre-aestivation and aestivation periods; and intermediate in characters during the breeding season (B. Sicard

Gerbillus nigeriae

pers. obs.). Efficient water conservation is indicated by extremely low values of body water turnover (ca. 12% of total body water per day) during aestivation (Sicard 1992). Dispersion occurs from Oct to mid-Jan when animals browse large areas in response to a decrease in water-rich resources. Pre-aestivation occurs from mid-Jan to Feb when animals collect and store seeds in the burrow. Aestivation occurs from Mar to May (during the dry-hot season; Sicard & Fuminier 1996; Sicard & Papillon 1996). Aestivation was not observed in Niger (Nomao & Gautun 2002).

Foraging and Food In N Burkina, diet is water-rich (seeds, arthropods and green vegetation) during the wet season and becomes water-poor (seeds only) during the dry hot season (Sicard 1992).

Social and Reproductive Behaviour Solitary and territorial. Home-ranges of ♂♂ overlap those of ♀♀ during the breeding period. Both home-range size and home-range shifts are minimal during aestivation, and are lower during the breeding season than during dispersion: home-range varies from $982 \pm 53 \text{ m}^2$ to $1581 \pm 101 \text{ m}^2$; home-range shift varies from $18 \pm 2 \text{ m}$ to $68 \pm 5 \text{ m}$. During pre-

aestivation, home-range size reaches a maximum ($2106 \pm 161 \text{ m}^2$) whereas home-range shift decreases near to zero (Sicard 1992).

Reproduction and Population Structure In N Burkina, maturation of the gonads occurs during aestivation and before the wet season begins (Apr–Jun). Mating and births are recorded during the wet season (Jun–Sep). Oestrus cycles occur throughout the year, but are shorter (5.1 ± 0.2 days, $n = 41$) between Jun and Sep than during the rest of the year (6.5 ± 0.2 days, $n = 27$) (Kyelem 1993). Male gonadotrophic activity and testis maturation start during aestivation (before the wet season) and stop after the wet season; e.g. plasma testosterone level is higher Apr–Sep ($1.57 \pm 0.15 \text{ ng/ml}$; $n = 37$) than during the rest of the year ($0.69 \pm 0.08 \text{ ng/ml}$; $n = 31$). Mean number of placental scars: 5.9 (range 3–7, $n = 21$). Litter-size: 3.4 (2–6, $n = 12$) (Sicard & Fuminier 1996).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Gerbillus occiduus OCCIDENTAL GERBIL

Fr. Gerbille occidentale; Ger. Westliche Rennmaus

Gerbillus occiduus Lay, 1975. Fieldiana Zool. 65: 94. Aoreora, Morocco.

Taxonomy Synonyms: none. Chromosome number: $2n = 40$ (all metacentric chromosomes), FN = 76 (Lay 1975).

Description Small gerbil. Dorsal pelage intermediate between cinnamon and buffy-brown; hairs grey at base, with buffy-brown terminal band. Ventral pelage pure white. Colour of dorsal and ventral pelage clearly delineated. Head with prominent postauricular and supraorbital white patches, and narrow but distinct dark eye-

ring. Ear slightly pigmented on distal edge. Soles of hindfoot hairy. Tail long (ca. 115% of HB), with a very small terminal dark brown pencil. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. tarabuli. Larger; chromosome number: $2n = 40$; desert to semi-desert regions of North Africa, eastwards to Libya and Chad.

G. gerbillus. Similar size; chromosome number: $2n = 42/43$; desert to semi-desert habitats of North Africa.

G. hoogstraali. Similar size; ear on average larger; chromosome number: $2n = 72$; known only from the Souss Plain (between High Atlas and Anti Atlas Mts).

G. hesperinus. Similar size; hindfoot probably smaller; chromosome number: $2n = 58$; known only from near Essaouira on the coast of Morocco north of the Middle Atlas Mts.

Cranial and pelage characters also distinguish these species (see respective profiles, and Lay 1975). *Gerbillus hoogstraali*, *G. hesperinus* and *G. occiduus* are reported to have allopatric ranges (Lay 1975).

Distribution Endemic to Africa. Sahara Arid BZ. Known only from Morocco – from the type locality, 80 km WSW of Goulimine, Morocco, and further south on the coast in the vicinity of Tarfaya (Aulagnier & Thévenot 1986).

Habitat Type locality is an area of sparsely vegetated sand dunes (Lay 1975).

Abundance No information.

Gerbillus occiduus

Remarks Litter-size: 3.45 (1–5, $n = 11$ litters from two pairs). Six of 16 progeny of one ♀ were partial albinos (Lay 1975).

Conservation IUCN Category: Data Deficient. Only known from the type locality, so may be threatened because of small populations numbers and limited geographic distribution.

Gerbillus percivali PERCIVAL'S GERBIL

Fr. Gerbille de Percival; Ger. Percivals Rennmaus

Gerbillus percivali (Dollman, 1914). Ann. Mag. Nat. Hist., ser. 8, 14: 488. Voi, Kenya.

Taxonomy Originally described in the genus *Dipodillus*. Regarded as a valid species by Lay (1983), although included in *G. pusillus* by Petter (1975a). Occurs sympatrically with *G. pusillus* in Kenya. It is also sympatric with *G. harwoodi* in the southern part of its range, and resembles *G. harwoodi* very closely. The three taxa – *G. percivali*, *G. pusillus* and *G. harwoodi* – may form a closely related species complex, or even be a single species. Referred to as a valid species by Musser & Carleton (1993) but later (2005) as a synonym of *G. pusillus*. Synonyms: none. Chromosome number: not known.

Description Very small dark gerbil with a long tail. Dorsal pelage dark shiny rusty-brown; dorsal hairs medium grey at base, rusty-brown terminally. Dorsal pelage dense. Ventral pelage pure

white, clearly delineated from colour of dorsal pelage. Limbs and feet white. Tail long (ca. 145% of HB), brown above with small brown and black bristles, paler below; longer black hairs form thin pencil on terminal third of tail. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. harwoodi. Similar in size and colour; tail relatively shorter (ca. 126% of HB); recorded from highlands of Kenya only.

G. pusillus. Similar in size and colour; tail relatively longer (ca. 160% of HB); hairs long and soft; drier habitats of C and S Kenya.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Known only from near Voi, SE Kenya.

Habitat 'Dry sandy plains' and 'trapped in long grass under thorn scrub' (collector's field note, at Maktou [BHNM]).

Abundance Rare; known only from a few specimens.

Remarks One ♀ contained three half-grown embryos in Aug.

Conservation IUCN Category: Data Deficient. Probably vulnerable because of small geographic range and apparent rarity.

Gerbillus perpallidus **PALE GERBIL**

Fr. Gerbille pâle; Ger. Helle Rennmaus

Gerbillus perpallidus Setzer, 1958. J. Egypt. Publ. Health Assoc. 33: 221. Bir Victoria, Egypt.

Taxonomy The taxonomy of this species is confused. Specimens now considered to represent this species were originally labelled as *G. tarabuli*, *G. andersoni* or *G. pyramidum*. May be closely related to *G. pyramidum*. Synonyms: none. Chromosome number: $2n = 40$, $FN = 76$ (Lay *et al.* 1975).

Description Small very pale gerbil with long soft pelage. Dorsal pelage pale sandy-orange to pinkish-cinnamon, without any darkening on the mid-dorsal line; dorsal hairs pale grey tipped with sandy-orange. Conspicuous white rump patch. Flanks pale sandy-white. Ventral pelage pure white. Crown of head and nose similar to back. Supraorbital, postorbital and postauricular white patches. Limbs and feet white. Sole of hindfoot hairy. Tail long (ca. 128% of HB), sandy above, white below, ending in small pencil of white hairs. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. pyramidum. Larger on average (HB: 109–135 mm) and heavier (WT: ca. 53 g); dorsal pelage orange-brown, darker on mid-line; chromosome number: $2n = 38$.

G. gerbillus. Smaller on average (HB: 77–104 mm) and lighter (WT: ca. 20 g); dorsal pelage orange; $2n = 42$ for ♀♀, chromosome number: $2n = 43$ for ♂♂.

G. andersoni. Slightly smaller on average (HB: 90–115 mm); dorsal pelage sandy-orange; chromosome number: $2n = 40$.

Distribution Endemic to Africa. Sahara Arid BZ. Recorded only from N Egypt, west of the Nile R.

Habitat Occurs in many habitats with very pale sand, either sandy wadis, coastal dunes or soft sand sheets. Near Wadi el Natroun, constructs burrows in the mud-sand beaches close to the lake where *Typha* rushes are growing (Osborn & Helmy 1980). Also occurs on barren slopes covered with ephemeral *Mesembryanthemum*.

Abundance Restricted, but not uncommon in suitable habitats.

Remarks Nocturnal, terrestrial. The very pale pelage, considerably paler than that of *G. pyramidum*, is very similar in colour to that of the pale sand where these gerbils live. Embryo number: 5 ($n = 1$; Apr). Three species of fleas have been collected on individuals and in nests (Hoogstraal & Traub 1965a).

Gerbillus perpallidus

Conservation IUCN Category: Least Concern.

***Gerbillus pulvinatus* CUSHIONED GERBIL (RHOD'S GERBIL)**

Fr. Gerbille d'Éthiopie; Ger. Polster-Rennmaus

Gerbillus pulvinatus Rhoads, 1896. Proc. Acad. Nat. Sci. Philadelphia, p. 537. Rusia, L. Rudolf (= L. Turkana), Ethiopia.

Taxonomy Recognized as a valid species by Lay (1983) and by Musser & Carleton (1993, 2005). Petter (1975) and Yalden *et al.* (1996) included *bilensis* (known only from type locality: Bilen, Ethiopia) as a synonym although Lay (1983) recognized *bilensis* as a valid species. Yalden *et al.* (1976) included *pulvinatus* within *G. pyramidum*. Synonyms: *bilensis*. Subspecies: none. Chromosome number: $2n = 62$, $FN = 84$ (Hubert 1978c).

Description Small gerbil. Dorsal pelage sandy-brown, slightly darker on mid-dorsal line; dorsal hairs dark grey at base, sandy-brown at terminal end. Flanks paler, hairs white with pale sandy-brown tips. Ventral pelage pure white. Colour of ventral pelage merges with colour of flanks. Crown of head and nose similar to back; supraorbital and postorbital white patches. Postauricular white patch inconspicuous. Chin, throat, limbs and feet white. Soles of hindfeet partly hairy; toes with fringe of fine bristle-like hairs. Tail long (ca. 140% of HB), sandy-brown above, white below; darker longer hairs form narrow pencil towards tip. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. dunni. Similar HB and T; longer HF; $2n = 74$; mostly allopatric except in Djibouti.

G. pusillus. Smaller HB and T; shorter HF; $2n = 34$; mostly allopatric except near L. Turkana, Kenya.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. The form '*pulvinatus*' (including *bilensis* and *dunni*) is only known from Ethiopia and Djibouti but is likely to occur also in N Kenya and the drier regions of Somalia (Yalden *et al.* 1996).

Habitat In the Omo Valley, Ethiopia, these gerbils live in dry grassland savanna, sparsely covered with trees, and prefer sandy soils (Hubert 1978c). In Djibouti, recorded amongst sparse vegetation, and in areas of volcanic rock with bushes and trees (Pearch *et al.* 2001).

Abundance Few specimens are known. Probably rare and with a very local distribution.

Remarks Other species parapatric with these gerbils in the Omo Valley are *Taterillus harringtoni* (now a synonym of *T. emini*), *Acomys*

*Gerbillus pulvinatus*

wilsoni, *Arvicanthis somalicus* (now *A. neumanni*), *Gerbillus pusillus* and *Xerus rutilus* (Hubert 1978c).

Conservation IUCN Category: Least Concern.

***Gerbillus pusillus* LEAST GERBIL**

Fr. Petite gerbille de Peters; Ger. Winzige Rennmaus

Gerbillus pusillus Peters, 1878. Monatsber. K. Preuss. Akad. Wiss. Berlin 1879: 201 (publ. 1878). Ndi and Kitui, Kenya.

Taxonomy Lay (1983), Petter (1975) and Musser & Carleton (1993, 2005) regard *G. pusillus* as a valid species. However, Petter (1975) suggested that *percivali* (here regarded as valid species) and *ruberrimus* may be synonymous with *G. pusillus*. (See also *G. percivali*.) Synonyms: *diminutus*, *ruberrimus*. Subspecies: none. Chromosome number: $2n = 34$ (Somalia; Capanna & Merani 1981).

Description Very small gerbil. Pelage long and soft. Dorsal pelage bright dark cinnamon to dark rusty-brown, lightly washed with black. Dorsal hairs medium grey at base, rusty-brown terminally, sometimes with black tip. Flanks paler. Ventral pelage pure white. Colour of ventral pelage clearly delineated from colour of flanks. Crown of head and nose dark rusty-brown; inconspicuous postorbital white patch. Cheek, chin, throat, limbs and feet white. Soles of hindfeet naked. Tail long (ca. 160% of HB), rusty-brown or ginger above, paler below; longer russet-brown and black hairs form conspicuous pencil on terminal third of tail.

Geographic Variation None recorded.

Similar Species

G. harwoodi. HB slightly larger (mean 75 mm); T shorter (mean 95 mm) and relatively shorter (ca 126%); C and SE Kenya, NE Tanzania.

G. percivali. HB slightly larger (mean 75 mm), T similar length, but relatively shorter (ca. 145% of HB); HF slightly shorter (mean 19.5 mm); SE Kenya only.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from scattered localities in Tanzania, Kenya, Ethiopia, Somalia and S Sudan.

Habitat Recorded in steppe habitats of coastal Somalia (Capanna & Merani 1981). In S Sudan, found in short grass on sandy soils (Dieterlen & Nikolaus 1985).

Abundance No information. Probably rare or uncommon; populations localized.

Remarks Subadults and juveniles in Jul (Somalia) and Aug (N Kenya). Remains found in owl pellets of Barn Owls *Tyto alba* in N Tanzania (SMF).

*Gerbillus pusillus*

Conservation IUCN Category: Least Concern.

***Gerbillus pyramidum* GREATER EGYPTIAN GERBIL**

Fr. Grande Gerbille d’Egypte; Ger. Grosse Ägyptische Rennmaus

Gerbillus pyramidum Geoffroy, 1803. Cat. Mamm. Mus. Natl Hist. Nat., Paris, p. 202. Giza Prov., Egypt.

Taxonomy The form *dongolanus* (known only from the type locality of Dongola, Sudan), here listed as a synonym, is recognized as a valid species by Musser & Carleton (1993, 2005). Setzer

& Ranck (1971) described *tibesti* from Chad as a subspecies of *G. pyramidum*; now placed as a synonym of *G. tarabuli* (Musser & Carleton 2005). Synonyms: *dongolanus*, *elbaensis*, *gedeedus*. Subspecies: none.

Chromosome number: $2n = 38$, all metacentric chromosomes, which excludes many forms from North Africa, West Africa and the Middle East that formerly have been referred to this species (Lay 1983, Granjon *et al.* 1999).

Description Small to medium-sized gerbil. Dorsal pelage medium/dark orange to brownish; hairs of variable length, grey at base, orange or brown at tip. Often darker along mid-dorsal region of back. Ventral pelage pure white. White rump patch of variable size, if present. Preorbital, postorbital and postauricular white marks, sometimes inconspicuous or absent. Fore- and hindfeet white; soles of hindfeet hairy. Tail long (125–145% of HB; cf. Osborn & Helmy 1980), with a more or less marked pencil of dark hairs. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

- G. nigeriae*. Usually smaller; soles of hindfeet hairy; chromosome number: $2n = 62\text{--}74$; northern Sahelian distribution from Mali to Chad.
- G. gerbillus*. Smaller; soles of hindfeet hairy; chromosome number: $2n = 42/43$; distributed in all desert to semi-desert habitats of North Africa.
- G. tarabuli*. Usually smaller; soles of hindfeet hairy; chromosome number: $2n = 40$; desert to semi-desert regions of North Africa, eastwards to Libya and Chad.

Distribution Endemic to Africa. Sahara Arid and Sahel Savanna BZs. Widespread in the desert areas of Sudan and Egypt, especially along the Nile Delta and Valley, and in oases (Happold 1967c, Osborn & Helmy 1980, Tawil & Niethammer 1989). Also recorded from Chad, Niger, N Mali and possibly Mauritania (Dobigny *et al.* 2001a, b, 2002b; Granjon & Dobigny 2003).

Habitat In Egypt, found in a variety of sandy habitats such as palm groves, surroundings of cultivations, barren sand and gravel areas, coastal plains and dunes; often found in grassy areas with *Panicum turgidum*, or under *Acacia radiana* or *Tamarix* sp. trees (Osborn & Helmy 1980). In N Mali, Niger and Chad, lives in similar situations, as well as in storehouses and gardens (Dobigny *et al.* 2001a, Granjon & Dobigny 2003).

Abundance Few quantitative data. The commonest gerbil in the deserts of N Sudan (Happold 1967c); up to 14 individuals seen during 1-hour nocturnal drive censuses, but less abundant than coexisting *Jaculus jaculus* (Happold 1968).

Adaptations Terrestrial and nocturnal. Burrows are similar to those of *Gerbillus gerbillus* (Osborn & Helmy 1980) and to those of *Gerbillus tarabuli* excavated by Petter (1961) in Algeria. In Sudan, burrows are often on sandy mounds or ridges around trees or bushes (Happold 1967c). Moulting observed at most times of the year in wild individuals, and occurring between 40 and 120 days of age in captivity (Happold 1968). Vocalizations include squeaking and chattering noises in handled newborn young and high-pitched squeaks in frightened adults (Happold 1968).

Foraging and Food In Sudan, stores seeds and grasses during the wet season (Jun–Aug), which are eaten when food becomes scarce (Happold 1967c). In captivity, feeds on grass, sunflower seed, millet, soft maize and cucumber (Happold 1968).

Social and Reproductive Behaviour Tends to be colonial. Mating behaviour observed in captivity: copulation lasted for 1–3 seconds, and was repeated a number of times (Happold 1968).

Reproduction and Population Structure In N Sudan, reproduction recorded during the wet season and the following cool dry season (Jun–Feb). Young and subadults (WT: 40 g) in population during Jul–Mar. Gestation: ca. 22 days. Litter-size in captivity: usually 3 (2–5). At birth, young hairless and blind; WT: 2 g. Fine covering of hair by Day 8–10. Ears open Day 16–18. Eyes open Day 19–20. First eat solid food Day 22. Weaned by Day 25–30. Adult HB ca. Day 80–90. Adult weight Day 110–120. Longevity up to two years in captivity (Happold 1968).

Predators, Parasites and Diseases No data on predation. In Sudan, ectoparasites include ticks, fleas and lice (in Happold 1968). In Egypt, fleas found in burrows and on individuals include *Synosternus cleopatrae* (commonest species), *Synosternus pallidus*, *Xenopsylla cheopis*, *Stenoponia acmaea* and *Pulex irritans* (Hoogstraal & Traub 1965a).

Conservation IUCN Category: Least Concern.

Gerbillus rosalia ROSALIND'S GERBIL (ROSALINDA GERBIL)

Fr. Gerbille de Rosalinde; Ger. Rosalindes Rennmaus

Gerbillus rosalia St Leger, 1929. Ann. Mag. Nat. Hist., ser. 10, 4: 295. Abu Zabad, 145 km SW El Obeid, Kordofan, Sudan.

Taxonomy The status of *rosalia* is uncertain because it is known only from the type locality and some nearby localities. Petter (1975a) suggested that *rosalia* may be a subspecies of *G. agag* (also known only from Sudan), although Setzer (1956) and Lay (1983) retain it as a valid species pending revision. In the original description, St Leger (1929) commented that *G. rosalia* was totally different from its 'near neighbours', *G. agag* and *G. pyramidum*. Synonyms: none. Chromosome number: not known.

Description Small dark gerbil. Dorsal pelage rich rusty-orange, darker on rump and on mid-dorsal line. Dorsal hairs grey at base with rusty-orange at terminal end; hairs on rump often with black tip. Flanks similar; hairs white at base with orange tips. Ventral pelage pure white. Colour of ventral pelage clearly delineated from colour of flanks. Crown of head and nose rusty-orange. Inconspicuous white postorbital patch. Cheeks, chin, throat, limbs and feet white. Soles of feet hairy. Tail long (ca. 120% of HB), covered with dense short hairs, orange-brown above, paler below; longer dark hairs at terminal end form narrow pencil. Nipples: not known.

Geographic Variation None recorded.

Similar Species Appears to be the only known species of *Gerbillus* in its area of distribution.

Distribution Endemic to Africa. Sudan Savanna BZ. Known from the region of Abu Zabad, SW of El Obeid, and a few other localities in C Sudan west of the White Nile (F. Dieterlen unpubl.; SMNS).

Habitat Grassy plains of Kordofan (St Leger 1929).

Abundance Known only from a few specimens.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Gerbillus rupicola **ROCK GERBIL**

Fr. Gerbille des rochers; Ger. Felsen-Rennmaus

Gerbillus rupicola Granjon, Aniskin, Volobouev and Sicard, 2002. J. Zool. Lond. 256: 183. Emnal'here, Mali.

Taxonomy Allocated to the genus *Dipodillus* by Musser & Carleton (2005). Synonyms: none. Chromosome number: $2n = 52$, $aFN = 68$.

Description Small gerbil. Dorsal pelage tawny-rufous; hairs grey at base. Ventral pelage white. Ventral colour well delineated from colour of flanks. Head with preorbital, supraorbital and postauricular white patches. Fore- and hindfeet white; soles of hindfoot naked. Tail very long (ca. 140% of HB), terminated by a marked pencil of dark hairs. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. campestris. Very similar externally; chromosome number: $2n = 56/58$; widespread. (See illustrations in Granjon *et al.* 2002b).

Distribution Endemic to Africa. Sahel Savanna BZ. As of 2003, known only from four individuals caught in two localities, 35 km apart.

Habitat Apparently associated with rocky habitats: the three specimens of the type series were caught on a rocky inselberg, the fourth one in fallen rocks at the foot of a cliff (J.-F. Cosson and E. Quesseveur pers. comm.).

Abundance No information.

Remarks Terrestrial and nocturnal. Apparently adapted to climb in rocky environments as does *Acomys* sp. with which it coexists (Granjon *et al.* 2002b).

Conservation IUCN Category: Data Deficient.

Gerbillus simoni **SIMON'S GERBIL**

Fr. Gerbille de Simon; Ger. Kleine Kurzschnanz-Rennmaus

Gerbillus simoni Lataste, 1881. Le Naturaliste 3: 499. Oued Magra, Algeria.

Taxonomy This species, known as *Dipodillus simoni* by some authors (Petter 1975a, Osborn & Helmy 1980, Musser & Carleton 2005), differs from all other gerbils by having a combination of unique characters – naked soles, tail similar in length to head and body, lack of pencil on tail, and special characters of the molar teeth (Petter 1959b, Schlitter & Setzer 1972; Cockrum *et al.* 1976). *Gerbillus simoni* has been described as 'a distinctive species' (Musser & Carleton

2005). Synonyms: *kaiseri*, *zakariai*. The status of *zakariai* is uncertain: considered as a synonym of *G. simoni* by Musser & Carleton (1993), but elevated to a species (*Dipodillus zakariai*) by Musser & Carleton (2005); *zakariai* is an insular taxon recorded only from the Kerkennah Is. (opposite the coastal city of Sfax, Tunisia) and related to *G. simoni* on the mainland. Subspecies: none. Chromosome number: $2n = 60$, $FN = 68, 69$ (Wassif *et al.* 1969, in Lay *et al.* 1975).

Description Very small gerbil with long soft fur and short tail; considered to be 'mouse-like'. Dorsal pelage pale brown to orange-brown; dorsal hairs dark or medium grey at base, with orange-brown subterminal band and black or orange tip. Flanks paler than back. Ventral pelage pure white. Colour of ventral pelage merges into colour of flanks. Crown of head and nose similar to back. Inconspicuous white supraorbital patch; conspicuous postorbital patch. Long vibrissae, some white, some black. Chin, throat, limbs and feet white. Soles of hindfeet naked. Tail relatively short (ca. 105% of HB, cf. other gerbils), covered with small brownish-orange bristles, upper and lower surfaces similar without pencil at terminal end; tail often thick (due to deposits of fat), especially at basal end. Nipples: not known.

Geographic Variation From west to east: increase in tail length, decrease in greatest width of skull and reduced inflation of auditory bullae (data from Algeria to Egypt: Osborn & Helmy 1980). There is also considerable variation in colour.

Similar Species No other species of gerbil has the unique characters listed above. Relative tail length of other species of *Gerbillus* is at least 120% of HB. Other species in the family Gerbillidae with short tails are larger and heavier (e.g. *Meriones* spp.: HB: 114–153 mm, WT: 54–112 g; *Pachyuromys* spp. HB: 93–121 mm, WT: 22–44 g; *Psammomys obesus* HB: 151–187 mm, WT: 116–205 g; data from Osborn & Helmy 1980).

Distribution Endemic to Africa. Mediterranean Coastal BZ and Sahara Arid BZ. Recorded from coastal regions from Morocco to Egypt (west of the Nile Delta). In Algeria, occurs in steppe habitats on the northern edge of the Hauts Plateaux but not in the coastal regions. A record in N Morocco needs verification.

Habitat Occurs in many habitats, especially where soils are loam or clay; e.g. 'Rich steppe country' and arable fields in Algeria; sparsely vegetated littoral desert and fallow fields in Tunisia; grassy valleys with lots of vegetation in Libya; and salt marshes, barley fields and vegetated slopes in Egypt.

Abundance 'Rather common' in vegetated salt marshes near the sea on the Egyptian coast (Hoogstraal 1963). In Libya, distribution is patchy; has not been found in many habitats that appear to be suitable (Ranck 1968).

Adaptations Nocturnal, terrestrial. Lives in burrows during daytime. Fat is stored in the tail during times of food abundance (in a similar manner to *Pachyuromys*); hence size of tail varies seasonally.

Foraging and Food No information.

Social and Reproductive Behaviour In Egypt, parapatric in salt marshes with *Gerbillus henleyi*, *G. amoenus*, *G. campestris* and two species

Gerbillus simoni

of jerboas, and in vegetated littoral desert with *G. andersoni*, *G. gerbillus*, three species of jerboas and *Meriones shawi* (Osborn & Helmy 1980).

Reproduction and Population Structure Embryo number: 4 (Tunisia, Oct; Harrison 1967) and 8 (Morocco, May; Schlitter & Setzer 1972). In captivity, gestation is 20 days and litter-size is 4–6; females enter oestrus 18–20 days after parturition (Lataste 1881 in Cockrum *et al.* 1976).

Predators. Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Gerbillus somalicus SOMALIAN GERBIL

Fr. Gerbille de Somalie; Ger. Somalische Rennmaus

Gerbillus somalicus (Thomas, 1910). Ann. Mag. Nat. Hist., ser. 8, 5: 197. Upper Sheikh, Somalia.

Taxonomy Originally described in the genus *Dipodillus*. Petter (1975a) placed *somalicus* as a subspecies of *G. campestris*, but Lay (1983) recognized it as a valid species pending revision. In the original description, Thomas (1910b) placed *somalicus* as a species of *Dipodillus*, and suggested that it was allied to *G. stigmonyx*. Probably part of the *campestris* species complex. Musser & Carleton (2005) refer to this species as *Dipodillus somalicus*. Synonyms: none. Chromosome number: not known.

Description Small long-haired gerbil with a long tail. Pelage long and soft. Dorsal pelage dark sandy-brown or orange-brown; dorsal hairs medium grey at base, orange-brown at terminal end, often with black tip. Flanks paler and brighter. Ventral pelage pure white. Colour of ventral pelage merges into colour of flanks. Head, nose and cheeks similar to back. Postauricular white patch. Chin, throat, limbs and feet white. Soles of hindfeet naked. Tail long (ca. 135% of HB), sandy-orange covered with short sandy-orange and black bristles above, paler below; long blackish-brown hairs form well-developed pencil on terminal third of tail. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. atticola. Larger in all dimensions; known from Barras (1050 m) and from coastal locations in Somalia.

G. brockmani. Very similar, but on average smaller body measurements, and smaller M^1 – M^3 ; recorded only from type locality (Barao).

Distribution Endemic to Africa. Somalia–Masai Bushland BZ; recorded only from the highland area of N Somalia.

Habitat No information.

Abundance Known only from a few specimens; probably rare.

Remarks The long soft pelage is probably an adaptation to cool nights during ‘winter’ in the highlands (1200–1400 m).

Conservation IUCN Category: Data Deficient.

Gerbillus stigmonyx KHARTOUM GERBIL

Fr. Gerbille de Khartoum; Ger. Khartum-Rennmaus

Gerbillus stigmonyx (Heuglin, 1877). Reise in Nordost-Afrika 2: 78. Khartoum, Sudan.

Taxonomy Originally described in the genus *Dipodillus*. Petter (1975a) listed *G. stigmonyx* (and *luteolus*) as synonyms of *G. campestris*, but Lay (1983) retained *G. stigmonyx* as a valid species pending revision. *Gerbillus stigmonyx*, *G. watersi* and *G. bottai* may form a closely

related species complex, and even belong to the same species (F. Dieterlen in litt.); see *G. bottai*. Musser & Carleton (2005) refer to this species as *Dipodillus stigmonyx*. Synonyms: none. Chromosome number: not known.

Description Small gerbil with long tail. Dorsal pelage sandy-orange, darker along the mid-dorsal line. Dorsal hairs medium grey at base, sandy-orange at terminal end, often with black tip. Flanks paler; hairs white at base, orange terminally, without black tips. Ventral pelage pure white. Colour of ventral pelage clearly delineated from colour of flanks. Crown of head and nose similar to back; longitudinal stripe of blackish hairs on nose. Postorbital and postauricular white patches. Cheeks, chin, throat, limbs and feet white. Soles of hindfeet naked. Tail long (ca. 115% of HB), sandy-orange above and below, longer darker hairs form pencil on terminal third or quarter of tail. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. watersi. Similar, with overlap in most measurements; HB on average slightly smaller (mean 81.5 mm); tail relatively longer (ca. 135% of HB); distribution mostly further north.

G. bottai. Similar, with overlap in most measurements; auditory bullae usually smaller (mean 8.7 mm); known only from a small region between the White Nile and Blue Nile rivers, south of Khartoum.

G. pyramidum. Larger in all body and skull dimensions; perhaps parapatric in C Sudan.

Distribution Endemic to Africa. Sahel Savanna BZ. Known only from a small region along the White Nile from Khartoum to El Kowa, Sudan.

Habitat No information.

Abundance Rare. Known only from a few specimens from four localities.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Gerbillus tarabuli TARABUL'S GERBIL (LIBYAN GERBIL)

Fr. Gerbille de Tarabul; Ger. Tarabuls Rennmaus

Gerbillus tarabuli Thomas, 1902. Proc. Zool. Soc. Lond. 1902: 5. Sebha, Libya.

Taxonomy Considered a valid species, distinct from *G. pyramidum*. Synonyms: *hamadensis*, *riggenbachi*, *tibesti*. Subspecies: none. Chromosome number: 2n = 40, aFN = 74 (Lay 1983, Granjon *et al.* 1999).

Description Small gerbil. Dorsal pelage sandy to light orange-brown; hairs grey at base on the back, white at base on flanks. Ventral pelage whitish to pure white, more or less well delineated from colour of flanks. Head with supraorbital and postauricular white patches. Fore- and hindfeet white; soles of hindfoot covered with

hairs of variable length. Tail very long (ca. 145% of HB), terminated by a marked pencil of usually dark hairs. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

G. nigeriae. Smaller on average; chromosome number: 2n = 62–74; northern Sahel Savanna BZ from Mali to Chad.

G. gerbillus. Smaller on average; chromosome number: 2n = 42/43; all desert to semi-desert habitats of North Africa.

G. pyramidum. Larger on average, with longer and more robust hindfoot; chromosome number: $2n = 38$; Nile Valley, and southern Sahara from Chad to Mali.

Distribution Endemic to Africa. Sahara Arid and Sahel Savanna BZs. Widespread in desert to semi-desert regions of North Africa, from Mauritania and Morocco to Libya, south to N Senegal, Mali, Niger and Chad (Granjon *et al.* 1999, Granjon & Dobigny 2003 and unpubl. data). Presence in N Senegal interpreted as a possible southwards extension of range following desertification (Duplantier *et al.* 1991).

Habitat Psammophile (sand-loving), but catholic in habitat choice, provided there is sand in the substrate (Petter 1961). In Mauritania, found in fixed dunes and sandy-clay plains (Klein *et al.* 1975, Granjon *et al.* 1997b), and associated with *Capparis-Panicum* vegetation in the Azzefal region (Klein *et al.* 1975). In Mali and Niger, occurs frequently in sand dunes where *Acacia* sp. or *Prosopis* sp. are present (L. Granjon & G. Dobigny unpubl.).

Abundance In coastal Mauritania, densities are 0.2–2 individuals/ha during the course of a year (Klein *et al.* 1975).

Capture rates of 3 to 5.3 individuals/100 trap-nights recorded in favourable habitats in March 1995 (Granjon *et al.* 1997b).

Adaptations Terrestrial and nocturnal. Burrow shallow (15–25 cm depth) but rather complex, and the entrances are plugged with sand during the day (Petter 1961). Homing behaviour was observed in nine (out of 13) individuals released 1000 m away from their burrows, and in two (out of 5) individuals released 2000 m away (Mermod 1970).

Foraging and Food No information.

Social and Reproductive Behaviour Less mobile than coexisting *G. nanus* and *G. gerbillus* in March 1995 in coastal Mauritania. Mean recapture distance 7.5 m (max 30 m) over a 4-day period (Cosson *et al.* 1997).

Reproduction and Population Structure In coastal Mauritania, main period of reproduction spans the whole of the wet season (Jul–Sep), from the end of hot dry season (Apr) to the following cool dry season (Nov); no reproductive activity observed in Jan–Feb. Embryo number: 3–6 (Klein *et al.* 1975).

Predators, Parasites and Diseases Occasionally preyed upon by Barn Owls *Tyto alba* in Mauritania (10 out of 210 prey items recorded; Granjon *et al.* 2002b).

Conservation IUCN Category: Least Concern.

Laurent Granjon

Gerbillus watersi WATERS'S GERBIL

Fr. Gerbille de Waters; Ger. Waters Rennmaus

Gerbillus watersi de Winton, 1901. Novit. Zool. 8: 399. Shendi, Sudan.

Taxonomy Setzer (1956), Petter (1975a) and Lay (1983) recognize *G. watersi* as a valid species. (Petter [1975a] – in error – also places *watersi* as a subspecies of *G. nanus*.) *Gerbillus watersi*, *G. bottai* and *G. stigmonyx* may form a closely related species complex, and may even belong to the same species (F. Dieterlen, in litt.);

(see species profile *G. bottai*). Musser & Carleton (2005) include *juliani* as a synonym, but Musser & Carleton (1993) and Lay (1983) retained *G. juliani* as a full species pending revision. Synonyms: none. Chromosome number: not known.

Description Small or very small pale gerbil with long tail. Dorsal pelage pale orange or sandy-orange, slightly darker along mid-dorsal line. Dorsal hairs grey at base, sandy-orange at terminal end, some with black tips. Flanks paler, hairs white at base with orange tips. Ventral pelage pure white. Colour of ventral pelage clearly delineated from colour of flanks. Crown of head and nose similar to back, darker on nose. Supraorbital and postauricular patches. Cheeks, chin, throat, limbs and feet white. Soles of hindfeet naked. Tail long (ca. 135% of HB), pale orange-brown above, well covered with short orange-brown hairs, white below; terminal half with longer dark hairs forming narrow pencil. See also Happold (1967c). Nipples: $2 + 2 = 8$ (specimen label, BMNH).

Geographic Variation None recorded.

Similar Species

G. pyramidum. Larger (HB: 110–110 mm, HF: 24–30 mm, WT: 39–51 g; Happold 1968): soles of hindfeet hairy; common.

G. stigmonyx: similar in size; very difficult to distinguish.

G. bottai. Similar in size; soles of hindfeet hairy or slightly hairy; very difficult to distinguish.

Distribution Endemic to Africa. Sahara Arid BZ/Sahel Savanna BZ. Recorded in NE Sudan, along the Nile Valley and on the Red Sea coast. Records of this species from Djibouti (Pearch *et al.* 2001) may represent *G. juliani*.

Habitat Near Khartoum, these gerbils live in sandy habitats with scattered trees and bushes.

Abundance Uncommon; found only in scattered localities. Much less common than *G. pyramidum*, which occurs in the same habitats.

Remarks Nocturnal, terrestrial. Lives in burrows during the daytime.

Conservation IUCN Category: Least Concern.

GENUS *Meriones*

Jirds

Meriones Illiger, 1811. Prodr. Syst. Mamm. Avium, p. 82. Type species: *Mus tamariscinus* Pallas, 1773.

The genus *Meriones* contains 16 species (Musser & Carleton 1993), which are widely distributed in North Africa, the Middle East, the Indian sub-continent, central Asia and China. Three or four species (see below) occur in Africa; all inhabit arid and semi-arid habitats of North Africa.

Species in the genus are large heavily built rat-like gerbils (commonly known as jirds). Dorsal pelage is sandy coloured, and the slender hairy tail is moderately long (usually ca. 75–100% of HB) with a black terminal pencil. Hindfeet slightly hairy. Skull is robust with well-developed supraorbital ridges and large inflated auditory bullae (Figure 51). Upper incisor teeth have a single

longitudinal groove. The cheekteeth are prismatic (successive rows are joined) and the laminae do not have cusps (at any stage of wear); they are similar in structure to those of *Sekeetamys* and (to a lesser extent) those of *Psammomys*. Dental formula: $I \frac{1}{1}, C \frac{0}{0}, P \frac{0}{0}, M \frac{3}{3} = 16$.

Species in the genus live in arid and semi-arid conditions, in a wide range of habitats including wadis, coastal areas, open plains and plateaux. They are nocturnal and diurnal (depending on the time of year). They feed on a wide variety of plants and seeds (but not saltbushes), have efficient water conservation and produce small quantities of concentrated urine (cf. *Psammomys*).

ABOVE: *Meriones crassus*.RIGHT: Figure 51. Skull and mandible of *Meriones libycus* (BMNH 8.7.12.17).**Table 26. Species in the genus *Meriones*. Arranged in alphabetical order.**

| Species | Length of tympanic bulla mean (range) (mm) | Suprameatus triangle | Tail | Claws | Inflation of mastoid bulla | Inflation of lip of auditory meatus | Accessory tympanum | Chromosome number |
|-------------------|--|--|-------------------------------------|-------|---|---|--------------------|-------------------|
| <i>M. crassus</i> | 15.5
(12.9–16.6) | Wide open; joins tympanic bulla | Conspicuous pencil at end of tail | Pale | Large; extends well posterior to paraoccipital process | Very conspicuous, touching zygomatic arch | Absent | 2n = 60, FN = 72 |
| <i>M. libycus</i> | 14.6
(13.2–15.7) | Closed; does not join to bulla | Conspicuous pencil at end of tail | Black | Moderate; extends slightly posterior to paraoccipital process | Conspicuous, touching or almost touching zygomatic arch | Present | 2n = 44, FN = 74 |
| <i>M. shawi</i> | 13.3
(12.4–14.2) | Partially open; narrow opening to tympanic bulla | Inconspicuous pencil at end of tail | Pale | Slight; does not extend posterior to paraoccipital process | Moderate, never touching zygomatic arch | Absent | 2n = 44, FN = 78 |

Table 27. Skull characters in the genera *Meriones*, *Psammomys*, *Sekeetamys* and *Pachyuromys*.

| Character | <i>Meriones</i> | <i>Psammomys</i> | <i>Sekeetamys</i> | <i>Pachyuromys</i> |
|------------------------------------|---|---|--|--|
| Supraorbital ridges | Well-developed | Well-developed | Well-developed | Slightly developed |
| Auditory bullae | Moderately inflated | Moderately inflated | Moderately inflated | Greatly inflated; posterior end well posterior to foramen magnum |
| Groove in each upper incisor tooth | Slight | None | Large | Slight |
| Form of cheekteeth | Prismatic | Slightly prismatic | Slightly prismatic | Prismatic |
| Anterior palatine foramina | Broad | Narrow | Narrow | Broad |
| Posterior palatine foramina | Mid M ¹ to mid M ² ; wide | Last lamina of M ¹ to first lamina of M ² ; very small and narrow | Mid M ¹ to posterior end of M ² ; wide | First lamina of M ¹ to mid M ² ; wide |
| Temporal and occipital ridges | None | Present | None | None |

RIGHT: Figure 52. Bulla region of three species of *Meriones* to show variation in opening of the suprameatus triangle to the mastoid, and position of meatus lip to the posterior edge of the zygomatic arch. (a) *M. crassus* (suprameatus triangle widely open, meatus lip touches zygomatic arch). (b) *M. libycus* (suprameatus triangle closed, meatus lip touches zygomatic arch). (c) *M. shawi* (suprameatus triangle slightly open, meatus lip does not touch zygomatic arch). 1 = suprameatal triangle, 2 = mastoid, 3 = meatus lip.

The number of African species in the genus is uncertain, and there is no recent review of the genus. Musser & Carleton (1993) recognize three species in Africa – *M. crassus*, *M. libycus* and *M. shawi*. The taxon *grandis*, formerly a subspecies of *M. shawi*, was raised to a full species by Musser & Carleton (2005), but is retained here as a subspecies of *M. shawi*. An additional species, *M. sacramenti*, occurs in NE Sinai (Egypt) and eastwards to Israel (Musser & Carleton 2005); it does not occur west of the Suez Canal and therefore is not considered as an African species (see Introduction: The Continent of Africa). For further information on this species, see Osborn & Helmy (1980) and Harrison & Bates (1991).

The three species of *Meriones* can be distinguished by numerous characters including head and body size, skull size, length of auditory bulla (Table 26), and the characteristics of the suprameatus triangle and meatus lip (Table 27, Figure 52). Other jirds (*Pachyuromys*, *Sekeetomys*) and sand rats (*Psammomys*) are superficially similar to *Meriones* but may be distinguished by several characteristics of the skull (Table 27).

E. Fichet-Calvet

Meriones crassus SUNDEVALL'S JIRD (SILKY JIRD)

Fr. Mérieone de Sundevall (Mérieone du désert); Ger. Sundevall Rennratte

Meriones crassus Sundevall, 1842. K. Svenska Vet. Akad., ser. 3, p. 233. Fount of Moses (Ain Musa), Sinai, Egypt.

Taxonomy Synonyms: *asyutensis*, *charon*, *ismahelis*, *longifrons*, *pallidus*, *pelerinus*, *perpallidus*, *swinhoi*, *tripolius*. Subspecies: none. Chromosome number: $2n = 60$, $FN = 70-74$ (Matthey 1957).

Description Medium-size jird. Pelage moderately long and soft. Dorsal pelage tawny or pale ochre; hairs grey at base, ochre or tawny at tip; grey of hair bases often shows on surface of pelage. Flanks paler. Ventral pelage greyish-white; hairs pale, grey at base, white at tip. Ears with small pale hairs, not pigmented. Conspicuous postauricular patch. Fore- and hindfeet white; soles partly hairy. Claws white. Tail long (ca. 100% of HB), well covered with hairs, grey at base, with small well-developed black terminal pencil. Skull: auditory bullae inflated (ca. 35–40% of GLS); narrow groove on each upper incisor; suprameatus triangle widely open, meatus lip touches zygomatic arch (Figure 52). Nipples: $2 + 2 = 8$.

Geographic Variation None recorded in Africa.

Similar Species (see also Figure 52)

M. libycus. Darker colour; smaller postauricular patch; black claws.

M. shawi. Similar colour; smaller postauricular patch; long line of clear colour on flanks.

Meriones crassus

Distribution Sahara Arid BZ (and occasionally Sahel Savanna BZ). Recorded from Mauritania and Morocco to Egypt (Petter 1961, Saint Girons & Petter 1965, Ranck 1968, Bernard 1969, Osborn & Helmy 1980, Aulagnier & Thévenot 1986, Kowalski & Rzebik-Kowalska 1991). Isolated records in Niger (Dobigny *et al.* 2002b), Mali (Heim de Balsac 1968) and N Sudan (Setzer 1956). Distribution is mostly south of the distribution of other *Meriones* spp. Extraliminally recorded from Israel to Afghanistan.

Habitat Arid habitats where vegetation is sparse. In Egypt, occurs in wadis with sparse cover of trees (mostly *Acacia* sp.), near date palms and rushes (but not in the Nile Delta), and in Algeria found in hamadas where few plants were growing. Also recorded in agricultural regions of S Tunisia (Bernard 1969). In the Negev Desert (Israel), animals move to new resource-rich habitats when previous habitats do not provide adequate food (Krasnov *et al.* 1996).

Abundance Common in suitable habitats. Densities range from 0.1/ha (Mar–Apr, Beni Abbes, Algeria; Petter 1961) to 11/ha (Koffler 1972).

Adaptations Nocturnal and terrestrial. Jirds are able to survive long periods of dry conditions feeding only on seeds and dry vegetation, but they require green vegetation for reproduction. Studies on water metabolism show a water influx that is higher in winter than in summer because of changes in diet (Degen *et al.* 1997). They excavate large complex burrow systems with many entrances in compact soil; a burrow may be used and altered by many generations of animals (Petter 1961).

Foraging and Food Granivorous and herbivorous. In Egypt, principal foods are fruits and seeds of *Colocynthis vulgaris*, *Anabasis articulata* and *Zilla* sp. (Osborn & Helmy 1980). In Israel, preferred green plants are *Atriplex halimus* and *Moricandia nitens* (Kam *et al.* 1997).

Social and Reproductive Behaviour Trapping results show that the maximum range length (RL, = distance between most distant captures of an individual) is large. In Algeria, mean RL for ♀♀ is 400 m and maximum is 960 m; for ♂♂, mean RL is 1500 m and maximum is 1870 m (Daly & Daly 1975a). Sometimes jirds may

move over even greater distances; for example, one ♂ returned to his burrow after being moved 6 km away (Petter 1961, 1968). Individuals are not socially tolerant, perhaps because they live in very arid habitats where resources are usually scarce (Daly & Daly 1975a). However, field and laboratory observations suggest that these jirds are sociable, but less so than *M. libycus*.

Reproduction and Population Structure In Egypt, ♀♀ are reproductively active in winter and early spring (Nov–Jun), and in Israel in Jan–Sep. Gestation: 18–22 days. Litter-size: 3.3 (1–5, n = 10). Young weaned: Day 17–23. Longevity: >18 months. Young form the highest percentage (50%) of the population in summer in Israel (Krasnov *et al.* 1996).

Predators, Parasites and Diseases Remains found in pellets of Eagle-owls *Bubo bubo* (0.1–1% occurrence) in S Morocco and Algeria (M. Thévenot pers. comm.). Recorded as a reservoir of the protozoan that causes zoonotic cutaneous leishmaniasis in humans in Egypt and Israel (Schlein *et al.* 1984) (see also *Psammomys obesus*).

Conservation IUCN Category: Least Concern.

Unlikely to be threatened because of large populations numbers and wide distribution.

Meriones libycus LIBYAN JIRD

Fr. Mérieux à queue rougeâtre (Mérieux de Libye); Ger. Libysche Rennratte

Meriones libycus Lichtenstein, 1823. Verz. Doublet. Zool. Mus. Univ. Berlin, p. 5. Alexandria, Egypt.

Taxonomy Many forms (ca. 28) are considered as synonyms (Musser & Carleton 1993, 2005). Major synonyms (in Africa): *caudatus*, *gaetulus*, *guyonii*, *mariae*, *melanurus*, *renaultii*, *schousboeii*. Subspecies: none. Chromosome number: 2n = 44, FN = 74 (Nadler & Lay 1967).

Description Medium-sized jird. Dorsal pelage pale tawny-grey; hairs grey at base, tawny-grey at tip. Thin orange line on flank separates dorsal colour from ventral colour. Ventral pelage white; hairs pale grey at base, white on terminal half. Ears not pigmented, with sparse

whitish-fawn hairs. Small white postauricular patch. Fore- and hindfeet white, soles partly hairy. Claws black. Tail long (ca. 100% of HB), reddish at base, with conspicuous black terminal tuft (much larger than in *M. crassus*). Skull: auditory bullae inflated (33–39% of GLS); narrow groove on each upper incisor; suprameatus triangle slightly open, meatus lip does not touch zygomatic arch (Figure 52). Nipples: 2 + 2 = 8.

Geographic Variation None recorded in Africa.

Similar Species (see also Figure 52)

M. crassus. Paler colour, larger postauricular patch; white claws.

M. shawi. Paler colour, darker ears on the edges; white claws.

Distribution Sahara Arid BZ. Widely distributed from Morocco to Egypt. In Morocco, occurs on the Atlantic coast south to Agadir and south to Atlas Mts (Aulagnier & Thévenot 1986). In Algeria, recorded on southern edge of Atlas and Aures Mts, and in Hoggar and Tassili (Kowalski & Rzebik-Kowalska 1991). Present in S Tunisia (Bernard 1969). In Libya, occurs in the coastal desert and throughout the Fezzan (Ranck 1968, Vesmanis 1985), and in N Egypt confined to coastal regions west of the Nile Valley (Osborn & Helmy 1980). Isolated record in Mauritania. Extraliminally recorded from Israel to Afghanistan.

Habitat In Algeria, found in many habitats on clay or sandy substrates including sandy mounds, wadi borders, plateaux (= hamadas) with perennial vegetation and halophytic steppes (Petter 1961, Daly & Daly 1975a, Zaim & Pascal 1989). Libyan Jirds require more vegetation in their habitat than do Sundevall's Jirds (Daly & Daly 1975a). Commonly occurs in large burrows under jujube bushes (*Zizyphus lotus*).

Abundance Populations fluctuate seasonally, between high numbers in spring and low numbers in summer (Zaim & Gautier 1993). In June, jirds comprised 24% (16/67) of small mammals inhabiting halophytic steppe in Morocco (Zaim & Pascal 1989). In Algeria, Petter noted 1 ind/20 ha in hamada near Beni Abbes.

Adaptations Diurnal and nocturnal. Digs shallow burrows with numerous openings, which are not plugged with sand or earth (Osborn & Helmy 1980). Activity patterns vary seasonally; in Jan, Libyan Jirds are often seen from sunrise to 08:30h, and in the afternoon from 16:00h to sunset. In Mar, diurnal activity is rarer than in winter (Daly & Daly 1975a, Agren 1979). Capable of surviving long periods of drought by feeding on stored seeds. Efficient water conservation: metabolic water is obtained from food, and water loss is reduced to a minimum by production of concentrated urine. Urine osmotic pressure (2640 mOsmol/L) is similar to that of *P. obesus* (2775 mOsmol/L) whereas water turnover is lower (Bradshaw *et al.* 1976, Ben Chaouacha-Chekir *et al.* 1983). Compared to Shaw's Jirds, thyroid function in Libyan jirds is reduced with a low iodine intake (Ben Chaouacha-Chekir 1996).

Foraging and Food Granivorous and herbivorous; diet is mainly seeds and grasses (no details available). Eats many different plants and seeds but prefers cereal and fruit seeds. Also feeds on succulent plants such as *Colocynthis vulgaris* (Chenopodiaceae) and *Zizyphus lotus*. Seeds are stored in special chambers in burrows (Petter 1961, Bernard 1969).

Social and Reproductive Behaviour Trapping data show that the maximum range length (RL, = distance between most distant captures of an individual) is large although not as large as for *M. crassus*. Mean RL for ♀♀ is 111 m (Nov–Dec) to 140 m (Jan–Feb) and maximum is 2280 m (n = 16); for ♂, mean RL is 159 m (Nov–Dec) to 1420 m (Jan–Feb), and maximum is 2420 m (n = 13). Home-ranges of ♀♀ sometimes (but rarely) overlap; home-ranges

Meriones libycus

of ♂♂ overlap with those of several ♀♀. Females may remain in the same home-range for many months. Numerous agonistic interactions between ♀♀ suggest a high degree of territoriality. Home-ranges are marked by secretions from mid-ventral glands and during sand-bathing (Agren 1979). Libyan Jirds produce many vocalizations for communication in sexual, agonistic and mother–pup interactions (Daly & Daly 1975a). Alarm signals include vocalization, foot-thumping (Daly & Daly 1975a) and holding the tail upright (so the black tuft is very obvious) like a flag (Harrison & Bates 1991).

Reproduction and Population Structure Breeding occurs only in winter, with pregnancies from Nov to Feb. Gestation: ca. 25 days (or up to 35 days if mother is lactating). Litter-size: 3 (2–4, n = 4) (Egypt; Osborn & Helmy 1980). Maturity: 3 months. Juveniles present in Mar–Apr in Beni Abbes (Algeria; Daly & Daly 1975a).

Predators, Parasites and Diseases Many species of raptors (e.g. *Tyto alba*, *Bubo bubo*, *Asio otus*, *Strix aluco*) prey on Libyan Jirds. Remains have been found in pellets of Eagle-owls in Morocco and in Algeria (10–57% occurrence, M. Thévenot pers. comm.). Honey Badgers *Mellivora capensis* prey on jirds in Morocco (M. Cuzin pers. comm.). Recorded as a reservoir of the protozoan that causes zoonotic cutaneous leishmaniasis in humans in Tunisia, in Libya and in Iran (see also *Psammomys obesus*). Endoparasitic nematodes recorded in Tunisia.

Conservation IUCN Category: Least Concern.

Meriones shawi SHAW'S JIRD

Fr. Mérieone de Shaw; Ger. Grosse Wüstenrennmaus (Shaws Rennratte)

Meriones shawi (Duvernoy, 1842). Mem. Soc. d'Hist. Nat. Strasbourg 3: 22. Oran, Algeria.

Taxonomy Originally described in the genus *Gerbillus* by Duvernoy in 1842. Many forms (ca. 11) described as subspecies are now considered as synonyms (Musser & Carlton 1993, 2005). The relationship between *M. shawi* and *M. libycus* is uncertain (Musser & Carlton 1993). The form *grandis* may be synonymous with *shawi*, or it may be a separate species as suggested by Pavlinov (2000) on the basis of craniometric variation (see also Musser & Carleton [2005] who consider *M. grandis* to be distinct from *M. shawi*). However, fertile hybrids have been obtained by cross-breeding *M. shawi* and *M. grandis*, suggesting that these taxa are conspecific (F. Petter & J.-A. Rioux unpubl.). Synonyms: *albipes*, *auratus*, *auziensis*, *azizi*, *crassibulla*, *grandis*, *isis*, *laticeps*, *longiceps*, *richardii*, *savii*, *sellysii*, *trouessarti*. Subspecies: three. Chromosome number: 2n = 44, FN = 78.

Description Medium-sized or large brown jird. Dorsal pelage ochre to pale tawny; hairs medium grey on basal half, ochre or pale tawny on terminal half; guard hairs black. Pelage colour varies geographically (see below). Slightly paler on flanks. Ventral colour pure white clearly delineated from colour of dorsal pelage by thin pale orange line. Head similar to dorsal pelage. Throat slightly yellow. Ears darkly pigmented, with scattered short tawny hairs. Conspicuous postauricular patch. Fore- and hindfeet white. Soles of

hindfeet partly hairy. Claws white. Tail long (ca. 95% of HB), well covered with sandy-brown hairs; upper surface with some black hairs and well-developed black pencil on terminal third. Skull: auditory bullae inflated (32–34% of GLS); narrow groove on each upper incisor; suprameatus triangle slightly open, meatus lip does not touch zygomatic arch (Figure 52). Considerable variation in colour and size between subspecies (see below). Nipples: 2 + 2 = 8.

Geographic Variation

M. s. shawi: Morocco to Egypt on the Mediterranean coast, except on the Tangier peninsula. Intermediate in size, colour and weight (70–120 g) compared with *grandis* and *trouessarti* (see Description above).

M. s. grandis: Morocco to NW Tunisia (overlapping with *M. s. shawi*?). Large (see below) with dark pelage (Saint Girons & Petter 1965).

M. s. trouessarti: Morocco to Tunisia between the Atlas Mts and the Sahara Desert, including the Chat Jeered. Small, pale and less heavy (see below); the most desert-adapted of all jirds.

Similar Species (see also Figure 52)

M. libycus. Darker colour, larger black terminal tuft on tail.

Distribution Endemic to Africa. Mediterranean Coastal BZ and northern parts of Sahara Arid BZ. Recorded from Morocco (where it occurs locally in mountains up to 2800 m [M. Cuzin pers. comm.]), Algeria, Tunisia, Libya and Egypt. Southern limit defined by oases south to High Atlas (29° N) and Aures Mts.

Habitat Widespread in plains and mountains, except for rocky habitats. Present in cereal crops, orchards and halophytic steppes, often in sympatry with *M. libycus* and various species of gerbils (Zaime & Pascal 1989). In Tunisia, particularly common in mounds colonized by jujube bushes (*Zizyphus lotus*) or along the hedgerows planted with prickly pear trees (*Opuntia* sp.) under which rodents build their burrows. Lives in sandy and clayey soils.

Abundance Populations fluctuate according to seasons. High densities occur in spring (40–100 ind/ha) and low densities in late summer and autumn (10–20 ind/ha). On occasions, population numbers may attain >200 ind/ha causing damage to cereal and food crops, and becoming major pests in agricultural fields (Bernard 1969, Zaime & Gautier 1988).

Adaptations Nocturnal and partly diurnal. The most hydrophilic jird with a higher water turnover and a lower urine osmotic pressure

Meriones shawi

(2040 mOsmol/L) than *M. libycus*. Also requires a higher iodine intake than *M. libycus* to maintain thyroid function (Ben Chaouacha-Chekir 1996).

Foraging and Food Herbivorous and opportunistic, eating many different plants and seeds. Diet varies according to season and habitat. In Morocco, preferred plants are species of Gramineae (*Sorghum halepense* and *Stipa retorta*), Papilionaceae (*Medicago hispida*) and Compositae (*Calendula aegyptica*). Also eats *Salsola vermiculata* (Chenopodiaceae) in spring and autumn, and arthropods in Jul (Zaime & Gautier 1989). Seeds are stored in special caches in the burrows.

Social and Reproductive Behaviour Colonial. Range length (distance between most distant captures of an individual) varies according to season and sex. Range length in spring (May–Jun) is 40–50 m, and 10–20 m in autumn and winter (Sep–Feb). Range length of males (ca. 70 m) is larger than for females (ca. 30 m), especially in uncultivated areas where food availability is low (Zaime & Gautier 1988). Communication between individuals is by foot-drumming and vocalizations (Bridelance 1989).

Reproduction and Population Structure Pregnancies recorded during wet season in Morocco (Nov–May; Zaime & Gautier 1988) and during dry season in Tunisia (Mar–Sep; Bernard 1969). Gestation: 21 days. Litter-size: 5.0 (3–8, with a maximum [mean 6.2] in Mar). Weight at birth: 3.5–6 g.

Predators, Parasites and Diseases Predators include foxes (*Vulpes vulpes*) and owls (*Tyto alba*, *Asio otus*, *Strix aluco*, *Bubo bubo*). Remains found in pellets of eagle-owls, comprised 0.5–3.5% of prey in Morocco (M. Thévenot pers. comm.) and 29% in N Algeria (Boukhamza *et al.* 1994). Reservoir of protozoan *Leishmania major*, which causes zoonotic cutaneous leishmaniasis (WHO 1990) (see also *Psammomys obesus*). Endoparasites in Tunisia include nematodes (Bernard 1987).

Conservation IUCN Category: Least Concern.

Shaw's Jirds are considered as pests in cultivated areas. Control measures may be necessary when population numbers are high.

GENUS *Microdillus*

Peel's Pygmy Gerbil

Microdillus Thomas, 1910. Ann. Mag. Nat. Hist., ser. 8, 5: 197. Type species: *Gerbillus peeli* de Winton, 1898.

Small gerbil-like rodents, often considered as a subgenus of *Gerbillus* but now recognized as a full genus (Petter 1975a, Musser & Carleton 1993, 2005). The genus has many gerbil-like features, but is characterized by small size, short tail and short square skull, which is abnormally bowed with a strong convex cranial profile. Unlike

Gerbillus, the upper third molar has three or four cusps (Petter 1977a). There is only one species, *Microdillus peeli*.

D. C. D. Happold

Microdillus peeli PEEL'S PYGMY GERBIL (SOMALI PYGMY GERBIL)

Fr. Gerbille pygmée de Somalie; Ger. Peels Koboldrennmaus

Microdillus peeli (de Winton, 1898). Ann. Mag. Nat. Hist., ser. 7, 1: 250. Eyk, Somalia (see Roche & Petter [1968] for map).Figure 53. Skull and mandible of *Microdillus peeli* (BMNH 8.4.9.9).*Microdillus peeli*

Taxonomy Originally described in the genus *Gerbillus* (see genus profile). Synonyms: none. Chromosome number: not known.

Description Very small gerbil with long pelage and short tail. Dorsal pelage dull orange-brown; dorsal hairs grey at base, with orange-brown tips. Pelage long and shaggy, so that grey bases of hairs may show on surface of pelage. Flanks paler; hairs whitish-grey or white at base. Ventral pelage pure white. Crown of head similar to back. Large eyes. Nose, lower cheeks, chin and throat white. Conspicuous supraorbital and postauricular white patches. Limbs and feet white. Soles of feet naked. Tail short (ca. 80% of HB), rather thick, slightly scaly, covered with brown or blackish bristles; without terminal pencil. Skull short and square; upper incisors opisthodont; zygomatic arch curves deeply downwards to form a large orbit; zygomatic plate small with almost vertical anterior face; auditory bullae (tympanic bullae and mastoids) large (Figure 53). Nipples: not known.

Geographic Variation None recorded.

Similar Species In all other species of gerbils of similar size (except *Desmodillus braueri*) the tail is longer than HB (Table 22).

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Known only from three localities in N and C Somalia. Not recorded from similar habitats in Ethiopia.

Habitat In C Somalia, found in sandy habitats. Other individuals recorded from hilly country (1500 m) in N Somalia.

Abundance Probably rare; there are few records and populations are scattered.

Remarks The tail appears to be used for fat storage in the same way as in *Pachyuromys duprasi* and *Gerbillus simoni*. The long shaggy pelage is probably an adaptation to the cool nights in winter (as in *G. somalicus*). Most specimens were 'caught on track at night'.

Conservation IUCN Category: Least Concern. However, limited geographic range and probable rarity may be cause for concern.

GENUS *Pachyuromys*

Fat-tailed Jird

Pachyuromys Lataste, 1880. Le Naturaliste, 2 (40): 313. Type species: *Pachyuromys duprasi* Lataste, 1880.

A monotypic genus widespread in semi-arid regions of North Africa. The genus is characterized by hairy soles on the hindfeet, relatively short thickened tail without pencil and often club-shaped at terminal end, faint groove on each upper incisor, prismatic molars (but to a lesser extent than in *Psammomys*, *Meriones* and *Sekeetomys*), very

inflated auditory bullae and wide posterior palatal foramina from mid M¹ to mid M² (see also Table 27). Further details are given in the species profile. The single species is *Pachyuromys duprasi*.

D. C. D. Happold

Pachyuromys duprasi FAT-TAILED JIRD

Fr. Gerbille à queue grosse; Ger. Fettschwanzmaus

Pachyuromys duprasi Lataste, 1880. Le Naturaliste, 2 (40): 313. Laghouat, Algeria.

Taxonomy Synonyms: *faroulti*, *natronensis*. Subspecies: none. Chromosome number: 2n = 54 (Qumsiyeh & Schlitter 1991).

Description Small pale-coloured rodent with thick short naked tail. Pelage long, fine and soft with a rather shaggy appearance. Dorsal pelage beige, sandy or pale orange; hairs dark grey at base, beige or sandy subterminal band, sometimes with black tip. Dorsal hairs may lie irregularly so black tips form small lines across the body. Ventral hairs pure white. Head similar in colour to dorsal pelage. Eyes large, dark. Ears comparatively small, with sparse longish hairs; ears often partially obscured by pelage of head and neck. Muzzle, lips, chin and throat white. Fore- and hindlimbs small. Forefoot with four digits, each with small claw. Hindfeet with five digits, each with small claw. Feet and digits well covered with long white hairs. Tail short (ca. 54% of HB), thick and club-shaped, naked and without scales; terminal pencil absent; size of tail varies seasonally (see below). Skull with

single faint groove on each upper incisor, braincase broad, auditory bullae very inflated (ca. 47% of GLS) and extending posteriorly to occiput (see also genus profile) (Figure 54). Nipples: not known.

Geographic Variation None recorded.

Pachyuromys duprasi.

Figure 54. Skull and mandible of *Pachyuromys duprasi* (BMNH 4.11.3.118).

*Pachyuromys duprasi*

Similar Species

Meriones spp. Larger HB (mean >130 mm); tail long (mean >135 mm, at least 95% of HB) with black terminal pencil; upper incisor teeth each with distinct longitudinal groove; auditory bulla smaller (mean 14.6–15.3 mm, ca. 32–40% of GLS).

Psammomys spp. Larger HB (mean 122 mm or larger); tail moderately long (mean ca. 115 mm, ca. 75% of HB) with black terminal pencil; upper incisor teeth without longitudinal groove; auditory bulla smaller (mean 13.3 mm, ca. 32–39% of GLS).

Distribution Endemic to Africa. Sahara Arid BZ. Recorded from Mauritania, Morocco, Algeria, Tunisia, Libya and Egypt. Distribution is widespread but very localized in semi-arid areas south of the Atlas Mts in Morocco and Algeria, and south of the coastal plain in Libya and Egypt. In Algeria extends southwards to ca. 25°N (as evidenced by remains in owl pellets). One isolated record in N Mali (Heim de Balsac 1968).

Habitat Hamadas with coarse pebbles and large boulders where vegetation is sparse, and along the edges of shallow dry water-courses that bisect the hamadas (Libya: Ranck 1968; Algeria: Daly & Daly 1979). Vegetated 'sand sheets' among sparse vegetation, and rocky deserts (Egypt: Osborn & Helmy 1980).

Abundance Generally rarely encountered. Few specimens are obtained even where other species of rodents are common (Daly & Daly 1979). These jirds were more abundant than usual at Beni-Abbès, Algeria, when there were large numbers of crickets (Petter 1961) (see also below).

Adaptations Nocturnal and terrestrial. Movement is by walking and running, and not by bounding as in many other gerbils (Petter 1961). Fat-tailed Jirds construct large complex burrows, often on slopes, where the sand is dry and has been compacted by ephemeral

rainstorms. Burrows are extensive, with numerous entrances (up to 12), which descend almost vertically into the burrow. Burrows are mostly shallow (5–10 cm) and rarely deeper than ca. 30 cm (max depth ca. 100 cm), and contain a nest. Burrows may be used for storage of food (Petter 1961). Fat-tailed Jirds become active at dusk, and may forage considerable distances (up to 2 km) from their burrows (Mermod 1970). One of the unique features of this species is its short fat tail, which is used to store fat; the tail alters in size according to season and to the amount of stored fat. In captivity, they are capable of entering 'torpor' for several days when Tb is 32–35 °C (Petter 1961). The auditory bullae are greatly inflated and, as in many species of gerbils and jerboas, provide for very sensitive perception of sounds.

Foraging and Food Omnivorous; mostly herbivorous. Detailed information on diet not available. In Algeria, burrows contained fragments of fruits (*Colocynthis vulgaris* and *Hyoscyamus niger*) (Petter 1961), and in Egypt, Fat-tailed Jirds have been observed to feed on *Anabasis articulata* and *A. monosperma* (Osborn & Helmy 1980). In captivity, they feed on grains, chopped meat, cheese, lettuce and lucerne; the addition of food containing meat to the diet stimulated reproduction (Petter 1961). The suggestion that snails may be eaten (Setzer 1957) needs confirmation.

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Gestation: ca. 21 days. Litter-size (in captivity): usually 3–5 (also 7 [n = 1], 9 [n = 1]). Births in captivity (Giza, Egypt) in Apr, May, Jul, Oct and Nov (Flower 1932). No data for wild populations, but likely to be opportunistic. Ears open Day 5–8, hair begins to grow Day 7–9; incisors erupt Day 11–15; eyes open Day 20–21; adult weight and body size ca. Week 10 (Petter 1961).

Predators, Parasites and Diseases Remains are common in owl pellets (Kowalski & Rzebiak-Kowalska 1991). One species of flea, *Xenopsylla nubica*, recorded in Algeria (Beaucornu & Kowalski 1985); seven species of fleas recorded on animals and in nests within burrows in Egypt: *Ctenocephalides felis*, *Synosternus cleopatrae*, *Xenopsylla conformis*, *X. ramesis*, *Stenopoma tripectinata*, *Nosopsyllus henleyi*, *Hopkinsipsylla oculata* (Hoogstraal & Traub 1965a). These fleas are also found on many other species of desert gerbils.

Conservation IUCN Category: Least Concern.

Although not common, the species has a widespread distribution and is unlikely to be threatened.

GENUS *Psammomys*

Sand Rats

Psammomys Cretzschmar, 1828. In: Rüppell, Atlas Reise Nordl. Afr., Zool. Säugeth., p. 56. Type species: *Psammomys obesus* Cretzschmar, 1828.

Psammomys obesus.

Figure 55. Skull and mandible of *Psammomys obesus* (BMNH 3.12.8.50).

The genus contains two species that live in semi-arid regions of N Africa, mostly north of the Sahara Desert. Habitats include salty lowlands, wadis and coastal deserts where saltbushes are prevalent.

Species in the genus are large heavily built rat-like gerbils. Dorsal pelage is sandy coloured, and the thick hairy tail is comparatively short (less than ca. 75% of HB) with a black terminal pencil. Hindfeet are broad and slightly hairy. The skull is robust, with well-developed supraorbital, temporal and occipital crests, large inflated auditory bullae (Figure 52), and narrow slit-like anterior and posterior palatal foramina. Upper incisors do not have a longitudinal groove (cf. *Meriones*); cheekteeth are similar in structure to those of *Meriones*. Cheekteeth do not have cusps (at any stage of wear) and the laminae are prismatic (as in *Meriones* and *Sekeetamys*) (Figure 55, see also Table 27).

Species in the genus are adapted for living in arid conditions. Their unique characters are diurnal activity and the production of large quantities of very concentrated urine. These characters are quite different to those of other arid-living small rodents and are associated with their ability to feed primarily on succulent saltbushes, rich in salt and water.

The genus *Psammomys* is placed in the subfamily Rhombomyini, which also includes the genera *Sekeetamys*, *Meriones* (and three other non-African genera [Pavlinov *et al.* 1990]). The number of species

in the genus is uncertain. Here, following Musser & Carleton (2005), two species are recognized – the larger *P. obesus* and smaller *P. vexillaris*. Several forms are considered now as synonyms of *P. obesus*, and *P. vexillaris* is also considered as a synonym of *P. obesus* by some authorities.

The two species of *Psammomys* are distinguished by body size, pelage colour and distribution.

E. Fichet-Calvet

Psammomys obesus FAT SAND RAT

Fr. Rat des sables obèse; Ger. Fette Sandratte

Psammomys obesus Cretzschmar, 1828. In: Rüppell, Atlas Reise Nordl. Afr., Zool. Säugeth., p. 58, pl. 22. Alexandria, Egypt.

Taxonomy Many forms have been described as species of *Psammomys*, including *algiricus* in Algeria, *tripolitanus* and *vexillaris* in Libya, *nicolli* and *obesus* in Egypt and *terraesantæ* in Palestine. All, except *vexillaris*, are now regarded as synonyms of *obesus* (Musser & Carleton 1993, 2005). The Fat Sand Rat is one of the best studied and most interesting of North African small rodents. Synonyms: *algiricus*, *dianae*, *elegans*, *nicolli*, *roudairi*, *terraesantæ*, *tripolitanus*. Subspecies: none. Chromosome number: $2n = 48$, $FN = 74-78$ (Qumsiyeh & Schlitter 1991).

Description Large heavily built sand rat with long pelage. Dorsal pelage ochre to tawny with long dark brown guard hairs; hairs dark grey at base, with orange or brown terminal band and black tip; width of bands varies geographically. Flanks and ventral pelage pale ochre. Massive head with large crown; vibrissae very long, pale or brown. Eyes large. Ears small and round, hairy, grey to ochre, set low on side of head. Small white postauricular patch. Fore- and hindlimbs short with buffy hairs on inner surface. Soles of hindfeet partly hairy; claws dark. Tail of moderate length (ca. 70% of HB), very hairy, ochre or brown with black terminal pencil. Skull: well-developed supraorbital ridges; auditory bullae inflated (ca. 32% of GLS); upper incisors smooth, without groove. Males tend to be larger than ♀♀. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

Psammomys vexillaris. On average smaller; pelage paler; ear smaller; E Algeria to W Libya only.

Meriones spp. Smaller (except for *M. shawi grandis*); dorsal pelage similar, but with white ventral pelage; ear on average larger; sympatric throughout most of geographic range.

Distribution Sahara Arid BZ. Widespread but disjunct distribution in salty lowlands, wadis and coastal deserts in Mauritania, Morocco, Algeria, Libya and Egypt where annual rainfall is 250–300 mm; also in southern part of the Haute Plateaux and Haggier Mts of Algeria. Outlier population on Red Sea coast of Sudan. Southern limit in the Sahara depends on the location of suitable habitats such as salt steppes near an oasis or a chott (= ancient lake). Extraliminally recorded from Syria, Jordan, Israel and parts of Arabian Peninsula.

Habitat Preferred habitats are succulent halophytic steppes (called *daya* in Egypt, and *sebkhet* in Tunisia) where the soil is moist, muddy and salty (salinity 9–30 g/L) (Petter 1961, Fichet-Calvet *et al.* 2000). The main plants in these habitats are saltbushes (*Arthrocnemum*, *Atriplex*, *Halocnemum*, *Salsola* and *Sueda*; family Chenopodiaceae), which are essential for the survival of these sand rats.

Abundance Generally common; populations fluctuate seasonally. Abundance in Tunisia ranged from 5 individuals/100 m of trap line

*Psammomys obesus*

(summer and early autumn) to 25/100 m (spring). In Morocco, densities (in Jul) of 42/ha have been recorded (Zaïme & Pascal 1988). Abundance also varies spatially in relation to flooding (in salt steppes). Multi-annual fluctuations have been recorded, but the causes are as yet unknown (Fichet-Calvet *et al.* 1999b, 2000).

Adaptations Fat Sand Rats live in an ecological niche utilized by no other species of rodent. They feed on the succulent leaves of saltbushes, which provide large amounts of water but are low in energy. The leaves of saltbushes contain salt (up to 12% by dry weight) as well as large quantities of water (up to 82%; Petter 1952). The kidneys are large and very efficient compared with those of other rodents, and are capable of producing a highly concentrated urine (salt concentration 2859 mmol/L, which is about four times as concentrated as seawater). Despite the high concentration of the urine, large quantities of urine have to be excreted each day (up to 25 ml/day) because of the high intake of water. This method of maintaining a positive water balance (and keeping cool in the desert during the daytime) is quite different to any other desert animal: it is a 'large water intake with large water loss' method, the large water loss being necessary because of the salty diet. This unusual method enables sand rats to exploit food that is inedible to other species, and to be diurnal when the ambient temperature is high (Ben Chaouacha-Chekir *et al.* 1983, Kam & Degen 1989).

Fat Sand Rats are diurnal and nocturnal. Activity above ground is usually 09:00h to 17:00h in winter, but confined to early morning and late afternoon in summer (Petter 1961, Ilan & Yom-Tov 1990). During the cooler months of the year, they bask in the sun.

Extensive complex burrows are excavated under bushes. Burrows are mostly less than 0.5 m deep but several metres in length, and have many entrances (usually 5–15 in Tunisia). A typical colony of Fat Sand Rats has a burrow under nearly every bush, with a maze of trails connecting burrows and food plants (Osborn & Helmy 1980). An actively used burrow can be recognized by fragments of saltbushes, faeces and urine marks at the entrance (Fichet-Calvet *et al.* 1999b). A chamber within the burrow may be used for faeces (Petter 1961). Burrows in salt marshes are abandoned in winter if flooded by water. An animal may use several burrows depending on climate and food resources, and lactating ♀♀ sometimes carry their offspring from one nest burrow to another.

Foraging and Food Herbivorous. Leaves and twigs of many species of saltbushes are the principal food. Fat Sand Rats forage 10–30 m around their burrows. They climb into low saltbushes and cut little branches, which they carry back to the main entrance of their burrows. The succulent leaves and twigs are eaten at the burrow entrance, where piles of discarded pieces are dropped onto the sand. Fragments of many species of plants are found in and near burrows: in Egypt, one burrow contained nine species of saltbush and another contained five species (Wassif 1953). Although food gathering does not take long, chewing and ingesting may take up to 4 h/day. Preferred plants vary depending on the locality, and include *Salsola vermiculata* (76.6% of the diet) in Morocco (Zaïme & Gautier 1989), *Suaeda mollis*, *Traganum nudatum* and *Salsola foetida* in Algeria (Daly & Daly 1973), *Suaeda fruticosa*, *Arthrocnemum glaucum* and *Salsola tetragona* in Tunisia (Fichet-Calvet *et al.* 2000) and *Suaeda monoïca*, *A. glaucum* and *Anabasis articulata* in Egypt (Wassif & Soliman 1979). Fat Sand Rats need to eat large quantities of food each day in order to provide adequate water for their metabolism (see above). Occupied burrows are positively correlated with the presence of green and vigorous Chenopod bushes (Daly & Daly 1974, Zaïme & Pascal 1989).

Social and Reproductive Behaviour Although Fat Sand Rats live in colonies, individuals tend to be solitary. Females have smaller range lengths (mean RL = 76 m) than ♂♂ (mean RL = 190 m). Only a small part of the range is used at a time: on a weekly basis, ♀♀ have a mean RL of 12 m and then move to an adjacent part of the range. Males have a mean weekly RL of 68 m; the range of a ♂ overlaps that of several ♀♀ so each ♀ is visited sequentially. Fat Sand Rats have to move (or ‘drift’) from one part of the range to another as they ‘eat out’ one patch of saltbushes and move on to another. Range lengths of juveniles when they are dispersing are larger than those of adults (e.g. juvenile ♂♂, mean 233 m; juvenile ♀♀, mean 208 m) (Daly & Daly 1975b).

Adult ♂♂ tend to be aggressive to juvenile ♂♂, chasing them from their home-range (Daly & Daly 1975b). Fat Sand Rats make sonic and ultrasonic squeals, associated sometimes with foot-drumming, when a conspecific is nearby. Predator warning squeals are brief, and produced close to the burrow (Bridelance 1989). Faeces and urine are used for marking the home-range (Fichet-Calvet *et al.* 1999b).

Reproduction and Population Structure Pregnancies occur during the cooler dry months of the year (Sep–Apr) with peaks of births in Oct and Feb (Tunisia: Fichet-Calvet *et al.* 1999a; Egypt:

Osborn & Helmy 1980). In years of low rainfall and low food availability, reproduction is restricted to Jan–Apr. Gestation: 24 days. Litter-size: 4.8 (2–8, n = 34; Fichet-Calvet *et al.* 1999a). Mean litter-size shows seasonal variation: 3.6 (n = 26) in Sep, and 6.0 (n = 18) in Jan–Mar. Weight at birth: 6–7 g. Weaned: Day 15. Adult size: Day 120. Sexual maturity: 3–6 months according to the season of birth. Longevity: 14–18 months (in field), 6 years (in captivity) (M. Kam unpubl.). Interval between litters: 35–44 days.

In Tunisia, age structure of population varies seasonally. In Sep (beginning of reproductive season), population is composed entirely of adult animals; these live and reproduce until the following Mar. Proportion of young increases from Oct to Mar (to max of 72% juveniles). In Mar, breeding population consists of two cohorts: a few old multiparous adults and some young primiparous young adults (born earlier in the season). Most of multiparous adults die at the end of breeding season (Daly & Daly 1975b, Amirat *et al.* 1977, Fichet-Calvet *et al.* 1999a).

Predators, Parasites and Diseases Predators include foxes (*Vulpes vulpes*), dogs, snakes (*Malpolon monspessulanus*) and raptors (*Buteo rufinus*, *Tyto alba*, *Bubo bubo*, *Strix aluco* and *Athene noctua*). Remains of Sand Rats have been found in pellets of Eurasian Eagle-owls *Bubo bubo* or Desert Eagle-owls *B. ascalaphus* (0.6–6% occurrence) in Morocco and Algeria (M. Thévenot pers. comm.). Occurrence in owl pellets is sometimes high (50%, S. Aulagnier pers. comm.). Fat Sand Rats are principal reservoir of a protozoa, *Leishmania major*, causing zoonotic cutaneous leishmaniasis in humans (WHO 1990). During the sylvatic plague cycle, the parasite circulates between the sand rats and sandflies living in the burrows. Bites of sandflies to humans cause cutaneous lesions. Population explosions of Fat Sand Rats increase the risk of transmission of this disease (70,000 cases in Tunisia from 1982 to 2000). Other parasites recorded from Sand Rats include bacteria (*Bartonella* spp., *Borrelia* spp.), Protozoa (*Babesia* spp.) and nematode and cestode worms. It is an important laboratory animal for studying disease such as diabetes.

Conservation IUCN Category: Least Concern.

Fat Sand Rats are common and widespread and not threatened. Control measures may be necessary when population numbers are high.

***Psammomys vexillaris* PALE SAND RAT (LESSER SAND RAT)**

Fr. Rat des sables pâle; Ger. Dünne Sandratte

Psammomys vexillaris Thomas, 1925. Ann. Mag. Nat. Hist., ser. 9, 16: 198. Bondjem, Libya.

Taxonomy Although *vexillaris* is sometimes considered synonymous with *obesus*, Ranck (1968) and Cockrum *et al.* (1977) consider, on the basis of skull morphology and chromosome numbers, that *vexillaris* is a valid species. Kowalski & Rzebik-Kowalska (1991) placed *vexillaris* as a synonym of *P. obesus* and therefore did not recognize this species in Algeria. Musser & Carleton (2005) recognize *P. vexillaris* pending revision of geographic variation in *P. obesus*. Synonyms: *edusa*. Subspecies: none. Chromosome number: 2n = 46, FN = 78.

Description Medium-sized gerbil, similar in form to *P. obesus* but smaller and paler. Dorsal pelage gold. Flanks and ventral pelage cream (or white). Ears small, hairy; postauricular patch absent. Fore- and hindlimbs short with white hairs on the inner surfaces. Soles of feet partly haired, claws dark. Tail long (ca. 86% of HB), hairy with a terminal pencil. Skull comparable to *P. obesus* but smaller; auditory bullae inflated (ca. 39% of GLS); upper incisors smooth, without groove. Nipples: not known.

Psammomys vexillaris

Geographic Variation None recorded.

Similar Species

Psammomys obesus. Usually larger, ventral pelage pale ochre; hindlimb buffy on inner surface; Mauritania and Morocco to Egypt and Sinai.

Meriones spp. Larger; dorsal pelage darker but with white ventral pelage; ear larger; sympatric throughout most of geographic range.

Distribution Endemic to Africa. Mediterranean Coastal and Sahara Arid BZs close to the Mediterranean Sea in E Algeria to W Libya. Recorded near Biskra, E Algeria (Thomas 1925); near Tozeur, Tunisia (Cockrum *et al.* 1977); and near Tripoli, Libya (Thomas 1925, Ranck 1968). Distribution of *P. vexillaris* is totally within the distribution of *P. obesus*.

Habitat Poorly known: alluvial soils on roadsides and hillocks (Ranck 1968). Inhabits sandier substrates than *P. obesus* (Cockrum *et al.* 1977).

Abundance Probably rare; known only from a few specimens.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

GENUS *Sekeetamys*

Bushy-tailed Jird

Sekeetamys Ellerman, 1947. Proc. Zool. Soc. Lond. 117: 271. Type species: *Gerbillus calurus* Thomas, 1892.

A monotypic genus distributed mainly in the Middle East with its western boundary in Egypt. The single species in the genus (*S. calurus*) occurs only in rocky habitats in semi-arid and arid environments. See species profile for further details.

Sekeetamys calurus.

The status of the genus is uncertain. Although the type for the genus was described as a *Gerbillus*, it was placed in a new genus, *Sekeetamys*, by Ellerman (1940). Other authorities have considered *calurus* as a species of *Gerbillus*, *Dipodillus* or *Meriones*. The genus is phylogenetically close to *Meriones* (Pavlinov *et al.* 1990) and also to *Microdillus* and *Gerbillus* (Tong 1989). The genus shows extensive chromosomal rearrangements, more so than in related genera, as well as special morphological features; on cytogenetic and allele evidence, it is closely related to *Psammomys* and *Meriones*, and less closely to *Desmodillus* (Qumsiyeh & Chesser 1988).

The distinguishing characters of the genus are the long very hairy tail, long narrow hindfeet, naked soles, large auditory bullae and narrow interorbital constriction. The teeth are intermediate between *Gerbillus* and *Meriones*. The single species is *Sekeetamys calurus*. See also Table 27.

Christiane Denys

Sekeetamys calurus BUSHY-TAILED JIRD

Fr. Gerbille à queue touffue; Ger. Bilchrennmaus

Sekeetamys calurus (Thomas, 1892). Ann. Mag. Nat. Hist., ser. 6, 9: 76. Tor, Sinai, Egypt.

Taxonomy Originally described in genus *Gerbillus*. Darker individuals from the Eastern Desert of Egypt described as a separate species, *S. mackrami* (Setzer 1961), are now recognized as a subspecies (Osborn & Helmy 1980). Synonyms: *mackrami*. Subspecies: two. Chromosome number: $2n = 38$, $aFN = 70$ (Qumsiyeh & Chesser 1988).

Description Medium-sized rodent with long bushy black tail, with white at tip. Pelage long (ca. 18–20 mm), soft, fine and dense. Dorsal pelage pale brownish-yellow to sandy-buff, speckled with black; hairs grey at base, with yellowish subterminal band and black tip. Flanks paler, with yellow or orange line from wrist to ankle. Ventral pelage pure white. Head similar in colour to back. Eyes large, dark. Ears large, darkly pigmented, rounded at tip, with sparse short hairs. Very long coarse vibrissae (up to 60 mm), mostly black, some white. Hindfeet long and narrow; upper surface with dense white hairs; soles naked. Tail very long (ca. 120% of HB), bushy throughout its length, densely covered with long black hairs, white at tip; tail is unlike that of any other species of gerbil. Skull: auditory bullae inflated, supraorbital and cranial ridges conspicuous, zygomatic arches compressed, rostrum long and narrow, interorbital constriction narrow, upper incisors opisthodont each with single longitudinal groove, molar teeth prismatic (Figure 56, see also Table 27). Nipples: $2 + 2 = 8$.

Figure 56. Skull and mandible of *Sekeetamys calurus* (BMNH 12.11.19.1).

Geographic Variation

S. c. calurus: Sinai Peninsula, Egypt. Paler dorsal pelage, sometimes with broad dark mid-dorsal stripe.

S. c. mackrami: Eastern Desert (between Nile R. and Red Sea coast), Egypt. Darker dorsal pelage with narrow dark mid-dorsal stripe.

Similar Species

Eliomys melanurus. Black bushy tail without white tip, black eye-ring and black stripe from back of eye to base of ear, auditory bullae only slightly inflated; mesic and semi-arid habitats.

Meriones spp. Sparsely haired pale tail with black pencil at tip, auditory bullae inflated but larger than in *Sekeetamys*; semi-arid and arid habitats.

Distribution Sahara Arid BZ. Recorded from Egypt (Eastern Desert and Sinai) and extreme NE Sudan. Extraliminally recorded from S Israel, Jordan and Saudi Arabia.

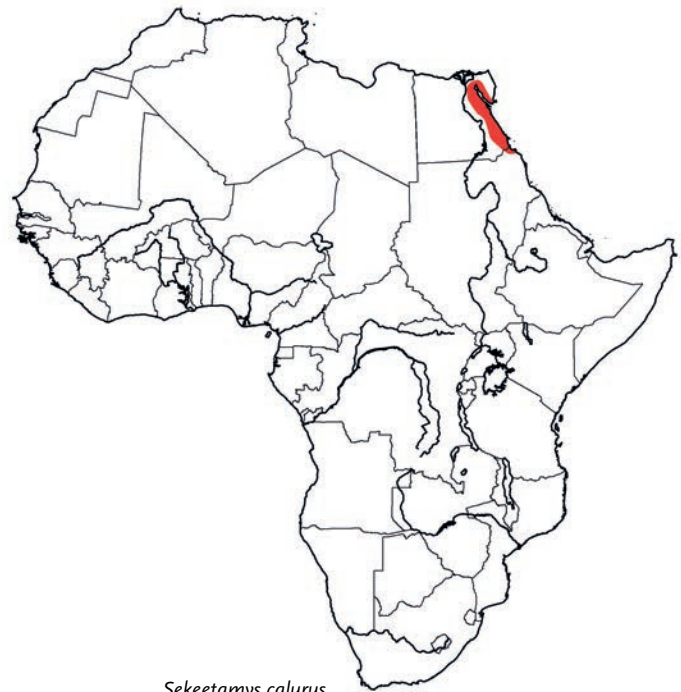

Habitat Rocky areas, sandstone cliffs, crevices in granite and amongst boulders in arid regions; also mountain regions in Sinai. Not recorded from sandy areas.

Abundance Uncertain; recorded as moderately abundant in Israel (Zahavi & Wahrman 1957). In Negev Highlands, Israel, density is 0.8–3.0 ind/ha; populations tend to be stable throughout the year (Shenbrot *et al.* 1999a).

Adaptations Nocturnal. Very agile; climbs rapidly on boulders and rock faces. During day rests in crevices of rocks and under boulders; does not dig burrows. At night, active for about 10.5 hours (Degan *et al.* 1986). During locomotion, the tail is held upright and curved forward in a squirrel-like fashion, and at times locomotion is bipedal. In Egypt, coexists with other rock-adapted species including *Eliomys quercinus*, *Acomys cahirinus*, *A. russatus* and *Gerbillus dasyurus* (Osborn & Helmy 1980).

Metabolic rate (as measured by oxygen consumption) is 31% (Degan *et al.* 1986) to 44% (Haim & Borut 1986) below predicted level at the thermoneutral zone ($T_a = 34\text{--}36^\circ\text{C}$) and variable depending on environmental conditions and temperature in different habitats. Food consumption is low (when compared with non-arid species of similar size). The dense pelage provides insulation against cold when active at night, yet thermal conductance is higher than expected (in spite of the dense pelage) enabling dissipation of body heat when T_a is high. Studies on water relations indicate that water flux was 99% of that predicted, and that *S. calurus* does not show any special adaptations for water conservation. The combination of a high proportion of insects in the diet, low food intake, relatively low metabolic rate and nocturnal activity (even though T_a is cold at night during some seasons) enables survival in an arid environment where resources are scarce (Degan *et al.* 1986, Haim & Borut 1986); this strategy for survival is quite different to that of granivorous desert rodents, which eat a low-water diet and exhibit many water-conservation abilities.

Foraging and Food Omnivorous. Detailed analysis of diet not available. Individuals trapped in crevices that contained parts of seeds and seed capsules, as well as bits of succulent plants. Insects

Sekeetamys calurus

probably supply 87% of food in wild-living individuals (Degan *et al.* 1986), although stomach contents of specimens (from Saudi Arabia) contained only green plant material (Nader 1974). Captive individuals ate cockroaches and crickets (Osborn & Helmy 1980).

Social and Reproductive Behaviour Mobility in ♂♂ greater than ♀♀. In ♂♂, mean distance between captures was 57 m (max 332 m); in ♀♀ 20 m (max 72 m). Adult ♂♂ have larger home-ranges (ca. 10–23 ha) than adult ♀♀ (0.7–0.8 ha) (Shenbrot *et al.* 1999a).

Reproduction and Population Structure Flower (1932) reported litters from captive animals every month of the year in Egypt except Sep. Litter-size (in captivity): 2.8 ($n = 47$ litters; max 6/litter [$n = 2$]). In the wild, period of reproduction appears to be limited and variable, and dependent on local conditions; longevity is probably high and reproductive success is low in natural conditions (Shenbrot *et al.* 1999a). Sex ratio of individuals captured in the Eastern Desert was 13 ♂♂ : 11 ♀♀ (Osborn & Helmy 1980).

Predators, Parasites and Diseases Preyed on by Eurasian Eagle-owls *Bubo bubo* at Gebel Migif, Egypt; remains of ten individuals found in pellets ($n = 45$ small mammals) (Goodman 1986). Four species of fleas recorded – *Xenopsylla nubica*, *X. dipodilli*, *X. conformus* and *Nesopsylla theodori* – from individuals near St Catharine's Monastery, Sinai, Egypt (Hoogstraal & Traub 1965a). Some of these species of fleas are also recorded from *Meriones crassus*.

Conservation IUCN Category: Least Concern.

GENUS *Taterillus*

Taterils (Gerbils)

Taterillus Thomas, 1910. Ann. Mag. Nat. Hist., ser. 8, 6: 222. Type species: *Gerbillus emini* Thomas, 1892.

Taterillus emini.

The genus *Taterillus* is endemic to Africa and contains eight species (Table 28). It has a widespread distribution, and occurs in the Sahel, Sudan and Guinea Savanna BZs from Mauritania to Somalia, from the Tilemsi Valley in N Mali to SW Nigeria, and from C Sudan to C Kenya. Typical habitats range from sandy dunes, thorny scrubs and woodland savannas, as well as fields, gardens and even human dwellings. Three species have fairly wide distributions (*T. gracilis* in West Africa, *T. congicus* in central Africa and *T. emini* in East Africa); the others mostly have very restricted distributions.

Species in the genus are small to medium-sized gerbils. Dorsal pelage is pale yellow to reddish-brown; ventral pelage, hands and feet are white. The head is characterized by a pointed muzzle, large eyes and elongated ears. The tail is longer than head and body, with soft hairs on its whole length, and a long terminal pencil of darker hairs. The hindfeet are long, naked and the soles are dark. The genus differs from *Gerbilliscus* (formerly *Tatera*) by overall smaller size, a more gracile appearance, elongated anterior palatal foramina, which end well forward of M¹, and longer slit-like posterior palatal foramina. It differs from *Gerbillus* by overall larger size, larger ears and longer and naked soles on the hindfeet; the skull is more robust with longer posterior palatal foramina and laminated molars without longitudinal crests connecting tooth cusps (Figure 57).

These gerbils are nocturnal and terrestrial. They dig burrows of various depth and complexity, and feed on seeds, stems, leaves and insects. They are often quite common, and sometimes subject to local

Figure 57. Skull and mandible of *Taterillus gracilis* (HC 1079).

population explosions that make them potential pests in agricultural fields. Cycles of abundance, as well as some eco-ethological and physiological attributes, are known for *T. gracilis* and *T. pygargus* in Senegal and for *T. petteri* in Burkina.

The taxonomy of the genus depends heavily on chromosomal information, as most species are very similar morphologically. Chromosome numbers are species-specific and vary from $2n = 14/15$ in *T. tranieri* to $2n = 54$ in *T. congicus*. One current problem concerns the characterization of *T. harringtoni* relative to *T. emini*: a karyotype of $2n = 44$ chromosomes has been attributed to both, and further studies are needed to clearly diagnose these two species; here, *harringtoni* is considered as a synonym of *T. emini*. Further cytotaxonomic investigations will undoubtedly lead to the discovery of new biological species, as suggested by the very complex chromosomal evolution of this group.

The genus can be divided in two distinct lineages as some species are characterized by a strong chromosomal synapomorphy, i.e. a double autosome–gonosome translocation. The males of one lineage (*T. arenarius*, *T. gracilis*, *T. petteri*, *T. pygargus*, *T. tranieri*) are

Table 28. Species in the genus *Taterillus*. Arranged in alphabetical order.

| Species | Chromosome number | Dorsal pelage | Notes |
|---------------------|------------------------------|---------------------------------|--|
| <i>T. arenarius</i> | 2n = 30 (♂ ♂), 2n = 31 (♀ ♀) | Pale sandy-yellow | Mauritania (Mali, Niger) |
| <i>T. congicus</i> | 2n = 54 | Chocolate-brown – reddish-brown | Central African Republic, Chad (Cameroon, Sudan, Uganda) |
| <i>T. emini</i> | 2n = 44 | Reddish-brown – orange | Sudan and Sahel BZs of eastern Africa, Somalia–Masai BZ |
| <i>T. gracilis</i> | 2n = 36 (♀ ♀), 2n = 37 (♂ ♂) | Reddish-yellow | Sudan and Sahel BZs of western Africa; widespread |
| <i>T. lacustris</i> | 2n = 28 (♀ ♀), 2n = 29 (♂ ♂) | Tawny | Area around L. Chad |
| <i>T. petteri</i> | 2n = 18 (♀ ♀), 2n = 19 (♂ ♂) | Pale orange – cinnamon | Sudan Savanna BZ (Burkina, Mali, Niger) |
| <i>T. pygargus</i> | 2n = 22 (♀ ♀), 2n = 23 (♂ ♂) | Yellow, reddish-brown | Sudan Savanna BZ (Senegal, Niger) |
| <i>T. tranieri</i> | 2n = 14 (♀ ♀), 2n = 15 (♂ ♂) | Buffy-brown | Sahel Savanna BZ (Mali) |

characterized by a set of three (X,Y1,Y2) sex chromosomes, whereas the males of the other lineage (*T. congicus*, *T. emini/harringtoni*, *T. lacustris*) are characterized by the classical XY sex chromosomes. (Females retain the usual XX sex chromosomes.) Again, the only non-ambiguous character to distinguish between species in the genus is the karyotype. Multivariate analyses of morphometric data have

been said to be of help, a result that was refuted by recent studies on karyotyped specimens.

The eight species are distinguished primarily on chromosome number but also on size and distribution (see also Table 28).

Laurent Granjon & Gauthier Dobigny

Taterillus arenarius SAND TATERIL (ROBBINS’S TATERIL)

Fr. Tâtérille des sables; Ger. Sahel-Rennmäuschen

Taterillus arenarius Robbins, 1974. Proc. Biol. Soc. Wash., 87: 399. Tiguent, Trarza Region, Mauritania.

Taxonomy Chromosome number distinguishes this species from its sibling species *T. gracilis*, *T. petteri*, *T. pygargus* and *T. tranieri* (Matthey 1969, Petter 1970, Volobouev & Granjon 1996, Dobigny *et al.* 2003). Synonyms: none. Chromosome number: 2n = 30 (♀ ♀), 2n = 31 (♂ ♂).

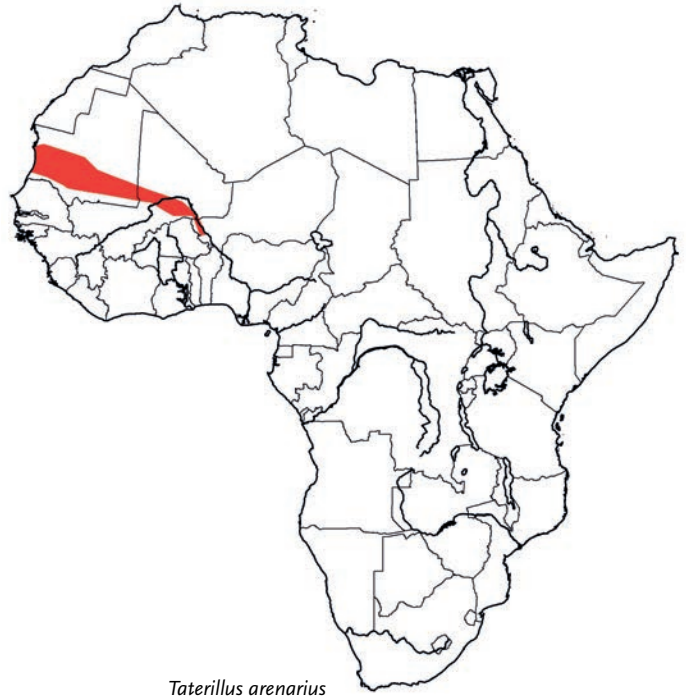

Description Medium-sized gerbil. Dorsal pelage pale sandy-yellow; hairs grey at base. Ventral pelage white, clearly delineated from dorsal pelage on flanks. Cheeks white, with white supraorbital and postorbital patches. Muzzle pointed, often with dark markings on upper part of nasal region. Large elongated ears. Large eyes. Fore- and hindfeet white. Hindfeet relatively long; soles dark and naked or nearly so; three median toes of similar length, Digit 1 short; rather long claws. Tail long (ca. 130–140% of HB) covered by short hairs, long terminal pencil of dark blackish-brown hairs. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

- T. gracilis*. Similar in morphology and size; chromosome number: 2n = 36/37; widely distributed in West Africa.
- T. petteri*. Similar in morphology and size; chromosome number: 2n = 18/19; Mali, Niger and Burkina mostly south of Niger R.
- T. pygargus*. Similar in morphology and size; chromosome number: 2n = 22/23; Senegal and Niger.
- T. tranieri*. Similar in morphology and size; chromosome number: 2n = 14/15; only in S Mauritania and W Mali.

Distribution Endemic to Africa. Sahel Savanna BZ. Presence confirmed (by chromosome number) only in Mauritania (Matthey 1969, Petter 1970, Volobouev & Granjon 1996). Recorded eastwards to Mali and Niger by Robbins (1974) on the basis of morphological

characters, but not yet confirmed by karyology (L. Granjon unpubl., Dobigny *et al.* 2002a).

Habitat Sandy-clay plains and inland dunes (Granjon *et al.* 1997b). Trapped in dry areas where average annual rainfall does not exceed 400 mm.

Abundance Densities probably low (Granjon *et al.* 1997b).

Remarks Found in pellets of Barn Owls *Tyto alba*; <3% of prey (Granjon *et al.* 2002b).

Conservation IUCN Category: Least Concern.

Taterillus congicus CONGO TATERIL

Fr. Tâtérille du Congo; Ger. Kongo-Rennmäuschen

Taterillus congicus Thomas, 1915. Ann. Mag. Nat. Hist., ser. 8, 16: 147. Poko, Upper Uele, DR Congo.

Taxonomy Synonyms: *clivus*. Subspecies: none. Chromosome number: 2n = 54 (Matthey & Petter 1970, Genest & Petter 1973, Tranier *et al.* 1973, G. Dobigny & L. Granjon unpubl.). Serum proteins also characterize this species (Tranier *et al.* 1973).

Description Medium-sized gerbil. Dorsal pelage chocolate- or reddish-brown to yellow; hairs grey at base. Ventral pelage white. Cheeks white; white supraorbital, postorbital and postauricular patches, more or less marked. Muzzle pointed. Ears large and elongated. Eyes large. Fore- and hindfeet white. Hindfeet long and narrow; soles dark and naked with narrow transverse band of white hairs behind the digits in some individuals; three median digits of hindfeet of similar length, Digit 1 shorter; rather long claws. Tail long (ca. 130–140% of HB), covered by short hairs, long terminal pencil of dark hairs. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

T. emini. Similar in morphology; chromosome number: 2n = 44; distributed from Somalia to Central African Republic.

T. lacustris. Similar in morphology; chromosome number: 2n = 29; restricted to L. Chad region.

Distribution Endemic to Africa. Widespread in parts of Sudan Savanna and Guinea Savanna BZs and parts of Northern Rainforest–Savanna Mosaic. Presence confirmed (by karyology) in Central African Republic and Chad (Matthey & Petter 1970, Genest & Petter 1973, Tranier *et al.* 1973, G. Dobigny & L. Granjon unpubl.) and N DR Congo (type locality). Presence suspected in Cameroon, Uganda and Sudan (Robbins 1977).

Habitat Thorn bush savannas in Sudan Savanna BZ, wooded savannas in Guinea Savanna BZ, and savanna islands in secondary rainforest habitats (Genest & Petter 1973). In SE Chad, found on sandy and sandy-clay soils with dense herbaceous cover and *Combretum* trees (C. Denys unpubl.).

Abundance Uncertain although locally common. Less common where syntopic with *Gerbilliscus* (= *Tatera*) spp. (ratio 1 *Taterillus* : 5 *Gerbilliscus*) in *Terminalia* savanna of S Central African Republic (Genest & Petter 1973).

Remarks Terrestrial and nocturnal. Digs burrows. Embryo number: 3 and 4 (n = 2); only 2 (of 30) ♀♀ were pregnant in Feb (Zakouma N. P., Chad; C. Denys unpubl.).

Conservation IUCN Category: Least Concern.

Taterillus emini **EMIN'S TATERIL**

Fr. Tâtérille d'Emin; Ger. Emins Rennmäuschen

Taterillus emini (Thomas, 1892). Ann. Mag. Nat. Hist., ser. 6, 9: 78. Wadelai, Uganda.

Taxonomy Originally described in the genus *Gerbillus*. The relationship between this species and *harringtoni* is uncertain. A karyotype of $2n = 44$ chromosomes has been associated with *T. emini* (Matthey 1969, Robbins 1973), but also with *harringtoni* (Robbins 1977). The difference between these two species is mainly one of size (skull, bullae, incisors), a character that has proved to be of little help in species allocation. Here, *harringtoni* is considered as a junior synonym of *T. emini*. Synonyms (of *emini*): *anthonyi*, *butleri*, *gygas*; (of *harringtoni*): *illustris*, *kadugliensis*, *lorenzi*, *lowei*, *melanops*, *meneghetti*, *nubilus*, *osgoodi*, *perluteus*, *rufus*, *tenebricus*, *zammerani*. Subspecies: none. Chromosome number: $2n = 44$.

Description Medium-sized gerbil. Dorsal pelage reddish-brown to orange; hairs grey at base, with reddish-brown to orange tip. Ventral pelage white. Cheeks white, with white eye-ring and usually a white postauricular patch. Muzzle pointed. Ears large and elongated. Eyes large. Fore- and hindfeet white. Hindfeet long and narrow; soles darkly pigmented, naked except for a narrow transverse band of white hairs behind the digits in some individuals; three median digits of hindfeet of similar length, Digit 1 shorter, rather long claws. Tail long (140–150% of HB), with short hairs and long terminal pencil of slightly darker hairs. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

T. congicus. Chromosome number: $2n = 54$; Central African Republic, S Chad and N DR Congo.

T. lacustris. Chromosome number: $2n = 29$; restricted to L. Chad region.

Distribution Endemic to Africa. Eastern parts of Sahel Savanna, Sudan Savanna and Guinea Savanna BZs, and Somalia–Masai Bushland BZ. Recorded from Somalia and Central African Republic (Genest & Petter 1973), Ethiopia (Matthey 1969) and Kenya (Robbins 1973). Karyotyped specimens recorded in Somalia to Central African Republic. Suspected to occur in Tanzania, N Uganda, NE DR Congo, Sudan and Chad (Robbins 1977), but no chromosomal data to confirm presence in these countries.

Habitat Uncertain. Collections from Somalia, Ethiopia and Central African Republic suggest an association with savanna habitats liable to flooding (Genest & Petter 1973).

Abundance No reliable information. Apparently much less abundant than *T. congicus* in Central African Republic (Genest & Petter 1973).

Remarks Probably terrestrial and nocturnal, as in other species of the genus; accurate information lacking.

Conservation IUCN Category: Least Concern.

Fr. Tâtérille gracile; Ger. Schlankes Rennmäuschen

Taterillus gracilis (Thomas, 1892). Ann. Mag. Nat. Hist., ser. 6, 9: 77. Gambia.

Taxonomy Originally described in the genus *Gerbillus*. Chromosome number (reviewed in Volobouev & Granjon 1996, Dobigny *et al.* 2003) and blood proteins (Tranier *et al.* 1973, Baron *et al.* 1974) distinguish this species from its sibling species *T. pygargus*, *T. arenarius* and *T. petteri*. Robertsonian polymorphism suspected (individuals with $2n = 36-39$, Matthey & Jotterand 1972, Dobigny *et al.* 2002a). Synonyms: *angelus*, *nigeriae*. Subspecies: none. Chromosome number: $2n = 36$ (♀ ♀), $2n = 37$ (♂ ♂).

Description Small- to medium-sized gerbil. Dorsal pelage yellow to reddish-brown; hairs grey at base with golden-yellow to orange-brown tip. Ventral pelage white, clearly delineated from dorsal pelage on flanks. Cheeks white; white supraorbital and postorbital patches. Muzzle pointed, often with dark blackish-brown markings on upper part of nasal region. Large elongated ears; large eyes. Fore- and hindfeet white. Hindfeet relatively long, soles dark and naked or nearly so; three median digits of similar length; Digit 1 short; rather long claws. Tail long (ca. 130–140% of HB), covered by short hairs, long terminal pencil of dark blackish-brown hairs. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

T. arenarius. Similar in morphology and size; chromosome number: $2n = 30/31$; Mauritania only.

T. petteri. Similar in morphology and size; chromosome number: $2n = 18/19$; Mali, Niger and Burkina mostly south of Niger R.

T. pygargus. Similar in morphology and size; chromosome number: $2n = 22/23$; Senegal and Niger.

T. tranieri. Similar in morphology and size; chromosome number: $2n = 14/15$; only in S Mauritania and W Mali. Soil characteristics may help distinguish between sympatric *T. gracilis* and *T. pygargus* (Hubert *et al.* 1977).

Distribution Endemic to Africa. Widely distributed in Sahel Savanna and Sudan Savanna BZs. Presence confirmed (by karyology) in Senegal (N of Gambia R.), Burkina, Mali, SW Niger, N Côte d'Ivoire, N Ghana, N Benin and SW Nigeria (Matthey & Petter 1970, Matthey & Jotterand 1972, Robbins 1974, Robbins & Van der Straeten 1996, Capanna, Dobigny, Granjon, Sicard and Tranier unpubl.). Also present in the Gambia (type-locality) and Togo (Robbins & Van der Straeten 1996).

Habitat Woodland savanna and thorny scrub where average annual rainfall is over 400 mm. Found on soils relatively rich in clay,

Taterillus gracilis

which retain water, and often associated with plants of Combretaceae (Hubert 1977, Hubert *et al.* 1977, Sicard *et al.* 1988). Frequently common in fields and gardens.

Abundance Often common when environmental conditions are favourable, and potentially subject to local large fluctuations in population numbers. In Bandia, Senegal (Nov 1975 to Mar 1981), average density 5.1/ha, varying between 0.4/ha during drought and 44/ha during optimal conditions (Hubert 1982). In Nigeria, widespread but localized, and considerably less common than *Gerbillurus kempi* in most savanna habitats (Happold 1975b, 1987).

Adaptations Terrestrial and nocturnal. Digs rather vertical and deep (55 cm) burrows without ramifications (Hubert *et al.* 1977). During favourable conditions (wet season and beginning of dry season), stores body fat and has high water turnover (up to 210 ml/kg/day). During the hot dry season, utilizes body fat and has low water turnover (down to 110 ml/kg/day; Hubert & Demarne 1981, Sicard *et al.* 1988, Sicard & Papillon 1996).

Foraging and Food Omnivorous. Feeds primarily on seeds, stems and leaves, but also eats insects, especially in the dry season.

Consumes millet when available (Senegal; Hubert *et al.* 1981b, Moro & Hubert 1983).

Social and Reproductive Behaviour Short-term movements of 20–40 m, within home-ranges of 700 m² (♀ ♀) to 750 m² (♂ ♂). Home-ranges of ♂ ♂ and ♀ ♀ often overlap, while home-ranges of ♂ ♂ rarely overlap. Movements increase during the reproductive season (Senegal; Hubert 1977).

Reproduction and Population Structure In Senegal, reproductive season quite long, usually starting during the wet season and extending more or less into the dry season, depending on resource availability and population densities. Breeding ♀ ♀ recorded during 3–4 months of the year when environmental conditions are poor (e.g. 1976/1977) and up to 10 months when environmental conditions are good (e.g. 1978/1979; Hubert 1982, Moro & Hubert 1983). Gestation: ca. 30 days. Embryo number (natural conditions): 1–8. Litter-size (in captivity): 3–5 (Hubert & Adam 1975, Hubert 1982). Sexual maturity: 12 weeks. Longevity up to two years in the wild, up to four years in captivity (Hubert 1982). Mortality rate may reach 30% per month (Hubert 1977). Mortality rate is higher for cohorts born during the dry season than for cohorts born during the wet season (Hubert 1982).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Probably not threatened due to widespread distribution, commonness and ability to live in cultivated areas.

Taterillus lacustris LAKE CHAD TATERIL

Fr. Tâtérille du Lac Chad; Ger. Tschadsee-Rennmäuschen

Taterillus lacustris (Thomas and Wroughton, 1907). Ann. Mag. Nat. Hist., ser. 7, 19: 370. L. Chad (Kaddai), Nigeria.

Taxonomy Originally described in the genus *Tatera*. Rosevear (1969) placed *lacustris* as a synonym of *T. gracilis*. Retained as a valid species by Petter (1975a), Robbins (1977) and Musser & Carleton (1993, 2005). Synonyms: none. Chromosome number: 2n = 28 (♀ ♀), 2n = 29 (♂ ♂) (Tranier *et al.* 1973, J.-M. Duplantier & K. Bâ unpubl.).

Description Small gerbil. Dorsal pelage tawny; hairs grey at base with orange to tawny-brown tip. Ventral pelage white, clearly delineated from dorsal pelage on flanks. Cheeks white; white supraorbital and postorbital patches. Muzzle pointed, often with dark blackish-brown markings on upper part of nasal region. Ears large and elongated. Eyes large. Fore- and hindfeet white. Hindfeet relatively long, soles dark and naked or nearly so; three median digits of similar length, Digit 1 short; rather long claws. Tail long (ca. 130–140% of HB), covered by short hairs, long terminal pencil of slightly darker brown hairs. Nipples: 2 + 2 = 8 (most probably).

Geographic Variation None recorded.

Similar Species

T. emini. Chromosome number: 2n = 44; on average slightly smaller; widely distributed to the east of L. Chad.

T. congicus. Chromosome number: 2n = 54; on average slightly larger in some measurements; distributed in S Chad, Central African Republic and N DR Congo.

Taterillus lacustris

Two other chromosomal forms, with chromosome number 2n = 22/23 and 2n = 24/25, have been described from the northern edge of L. Chad and undoubtedly correspond to new species (Dobigny *et al.* 2002a, Granjon & Dobigny 2003).

Distribution Endemic to Africa. Sahel Savanna and Sudan Savanna BZs near to L. Chad. Only known from NE Nigeria, and from N Cameroon just south of L. Chad.

Habitat Bushes, fallow lands and edges of fields in N Cameroon (J.-M. Duplantier & K. Bâ unpubl.).

Abundance No information.

Remarks Probably terrestrial and nocturnal. Some specimens in Nigeria were caught on the shores of L. Chad, which suggests that they may prefer a mesic habitat, or at least access to permanent water (Happold 1987).

Conservation IUCN Category: Least Concern.

The gradual drying of L. Chad during the latter years of the twentieth century may be a threat, especially if this species requires damp mesic conditions.

Taterillus petteri PETTER'S TATERIL

Fr. Tâtérille de Petter; Ger. Petters Rennmäuschen

Taterillus petteri Gautun, Tranier and Sicard, 1985. Mammalia, 52: 188. Near Oursi Pond (14° 38' N–0° 26' W), Burkina. 330 m.

Taxonomy Belongs to a group of sibling species (*T. pygargus*, *T. arenarius* and *T. gracilis*) distinguishable by their karyotypes (Sicard *et al.* 1988, Volobouev & Granjon 1996). Synonyms: none. Chromosome number: 2n = 18 (♀ ♀), 2n = 19 (♂ ♂).

Description Small to medium-sized gerbil. Dorsal pelage pale orange to cinnamon; hairs grey at base. Ventral pelage white, clearly delineated from dorsal pelage on flanks. Lower part of cheeks white; white postauricular, supraorbital and postorbital patches. Large elongated ears; large eyes. Fore- and hindfeet white; hindfeet long with dark soles. Tail long (ca. 125% of HB), covered with short hairs, long terminal pencil of dark hairs. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

T. arenarius. Similar in morphology and size; chromosome number: 2n = 30/31; Mauritania only.

T. gracilis. Similar in morphology and size; chromosome number: 2n = 36/37; widely distributed in West Africa.

T. pygargus. Similar in morphology and size; chromosome number: 2n = 22/23; Senegal and Niger.

T. tranieri. Similar in morphology and size; chromosome number: 2n = 14/15; S Mauritania and W Mali.

Distribution Endemic to Africa. Sahel Savanna BZ. Presence confirmed by karyotype data only in Burkina, Niger and Mali, mostly on the right side of Niger R. (Sicard *et al.* 1988, B. Sicard unpubl.).

Habitat Sahel savanna where annual rainfall is 300–500 mm. Occupies sandy veneers, sandy cultivated lands and more rarely sand dunes.

Taterillus petteri

Abundance In N Burkina, more abundant on sandy veneers (0–50 ind/ha) than on sand dunes (0–20 ind/ha); seems not to be subject to local population explosions (Sicard 1987).

Adaptations Terrestrial and nocturnal. In N Burkina, burrows are simple and superficial during the dispersion period (dry cool season; Oct–Jan), more complex, deep and filled with seeds during the pre-aestivation and aestivation periods (cool to hot dry seasons; Jan–May), and intermediate in their characteristics during the

breeding period (wet season; Jun–Sep) (B. Sicard unpubl.). Body water turnover reaches maximal values during breeding period (30–48% of total body water/day), decreases during the dispersion period (ca. 25%) and is extremely low during aestivation (ca. 9%) (Sicard 1992). Due to particular physiological mechanisms, triggering of aestivation occurs prior to the dry and hot season (Sicard & Fuminier 1994), and triggering of reproduction occurs prior to the wet season (Sicard & Fuminier 1996).

Foraging and Food Diet is water-rich (seeds, arthropods and green vegetation) during the wet season and water-poor (seeds) during the dry hot season (Sicard 1987, 1992).

Social and Reproductive Behaviour In N Burkina, solitary and territorial; territories of ♂♂ overlap those of ♀♀ during the breeding season. Home-range varies seasonally: during the dispersion period it is $1875 \pm 168 \text{ m}^2$, increases to $2324 \pm 196 \text{ m}^2$ during the pre-aestivation period, decreases to a minimum during aestivation, and then increases again to $1234 \pm 196 \text{ m}^2$ during the breeding period. Several individuals have been observed to excavate burrows together (B. Sicard unpubl.).

Reproduction and Population Structure In N Burkina, ♀♀ have oestrous cycles throughout the year. Births occur in Jun–Sep. Embryonic scars: 5.4 (3–6), $n = 17$. Litter-size in Burkina: 3 (2–6, $n = 12$; Sicard & Fuminier 1996). One observation in Mali

indicates a litter-size of seven (B. Sicard & L. Granjon unpubl.). In males, endocrine testicular activity (plasma testosterone level) is higher between Apr and Sep ($1.71 \pm 0.22 \text{ ng/ml}$; $n = 15$) than during the rest of the year ($0.46 \pm 0.2 \text{ ng/ml}$; $n = 11$) (B. Sicard & M. Kyelem unpubl.).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Taterillus pygargus SENEGAL TATERIL (CUVIER'S TATERIL)

Fr. Tâtérille de Cuvier; Ger. Senegal-Rennmäuschen

Taterillus pygargus (F. Cuvier, 1838). Trans. Zool. Soc. Lond. 2: 142. Saint Louis (?), Senegal.

Taxonomy Chromosome number (review in Volobouev & Granjon 1996, Dobigny *et al.* 2003) and blood proteins (Baron *et al.* 1974) distinguish this species from its sibling species *T. arenarius*, *T. gracilis*, *T. petteri* and *T. tranieri*. Synonyms: none. Chromosome number: $2n = 22$ (♀♀), $2n = 23$ (♂♂).

Description Small gerbil. Dorsal pelage yellow to reddish-brown; hairs grey at base with golden-yellow to orange tip. Ventral pelage white, clearly delineated from dorsal pelage on flanks. Cheeks white; white supraorbital and postorbital patches. Muzzle pointed, often with dark blackish-brown markings on upper part of nasal region. Large elongated ears. Large eyes. Fore- and hindfeet white. Hindfeet relatively long, soles dark and naked or nearly so, three median digits of similar length, Digit 1 short, rather long claws. Tail long (ca. 130–140% of HB), covered by short hairs, long terminal pencil of dark blackish-brown hairs. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

T. arenarius. Similar in morphology and size; chromosome number: $2n = 30/31$; Mauritania only.

T. gracilis. Similar in morphology and size; chromosome number: $2n = 36/37$; widely distributed in West Africa. Presence on different soil types (see species profiles) may help distinguish between sympatric *T. gracilis* and *T. pygargus* (Hubert *et al.* 1977).
T. petteri. Similar in morphology and size; chromosome number: $2n = 18/19$; Mali, Niger and Burkina mostly south of Niger R.
T. tranieri. Similar in morphology and size; chromosome number: $2n = 14/15$; S Mauritania and W Mali.

Distribution Endemic to Africa. Sahel Savanna and Sudan Savanna BZs of West Africa. Presence confirmed (by karyology) only in Senegal (Matthey & Jotterand 1972) and Niger (Dobigny *et al.* 2002); said to occur in Mauritania by Robbins (1974) on the basis of morphological characters.

Habitat Bush savanna and thorny scrub where average annual rainfall is ca. 300–800 mm. Inhabits recent sand dunes and soils poor in clay content that drain easily. Found in habitats where *Gutierrezia* sp. and *Acacia albida* are common, as well as habitats dominated by plants of family Poaceae (Hubert *et al.* 1977, Poulet 1982). Also present in cultivated areas.

Abundance Often common when environmental conditions are favourable, and potentially subject to local population explosions. In

Taterillus pygargus

the Sahel Savanna BZ of Senegal (1970–1976), densities varied from 0/ha after the drought of 1972 to 180/ha after the good wet season of 1975 (Poulet 1978). Much more abundant than *T. gracilis* in N Senegal, and becoming less common further south (Poulet 1982).

Adaptations Terrestrial and nocturnal. Digs burrows in sandy soils at periods when soil is not too hard during a short period between the end of the rains and the beginning of the dry season. Burrows have several entrances and ramifications, are usually less than 35 cm deep, but may be deeper during the dry season to reach moister conditions (Hubert *et al.* 1977, Poulet 1982).

Foraging and Food Granivorous and insectivorous (Poulet 1982).

Social and Reproductive Behaviour Home-ranges of ♀♀ do not overlap, but home-ranges of ♂♂ may overlap with those of several other individuals, principally ♀♀. Home-range: 400–

700 m² for ♀♀; up to 1500 m² for ♂♂ corresponding to larger movements of ♂♂, especially during the breeding season. High rate of dispersal for juveniles, followed by settlement (as adults) as the reproductive season approaches. Individuals change burrows at end of the reproductive season, usually within established home-ranges (Fete Ole, Senegal, 1969–72; Poulet 1972a).

Reproduction and Population Structure In Senegal, the length of the reproductive season is variable: it starts in the second half of the wet season (usually Sep) and lasts for 2–8 months, depending on the amount of rainfall (Poulet 1978, 1982). Gestation: 26 days. Embryo number: generally 3–7 (in natural conditions; Poulet 1982). Litter-size (in captivity): 4–6. Weaning: Day 20–21. Sex ratio: 1 : 1 (Hubert & Adam 1975). Sexual maturity: Week 12 (♂♂), Week 8 (♀♀). Monthly mean mortality rate may reach 22% (Poulet 1972b).

Predators, Parasites and Diseases Reptiles (especially *Psammophis sibilans*, owls (especially *Tyto alba* and *Otus leucotis*) and carnivores (especially *Felis libyca*, *Vulpes pallida*, *Canis aureus* and *Genetta genetta*) are known predators (Poulet 1982).

Conservation IUCN Category: Least Concern.

Taterillus tranieri TRANIER'S TATERIL

Fr. Tâtérille de Tranier; Ger. Traniens Rennmäuschen

Taterillus tranieri Dobigny, Granjon, Aniskin, Bâ and Volobouev, 2003. Mammal. Biol. 68: 301. Dilly, Mali.

Taxonomy Chromosome number distinguishes this species from its sibling species *T. arenarius*, *T. gracilis*, *T. petteri* and *T. pygargus* (Volobouev & Granjon 1996, Dobigny *et al.* 2003). Only known from the type series (n = 4). Synonyms: none. Chromosome number: 2n = 14 (♀♀), 2n = 15 (♂♂).

Description Medium-sized gerbil. Dorsal pelage buffy-brown, with a slight greyish (specimens from Mali) to reddish-brown (specimens from Mauritania) tinge; hairs grey at base. Ventral pelage white. Cheeks white; white supraorbital and postorbital patches,

more or less marked. Muzzle pointed. Ears large and elongated. Eyes large. Fore- and hindfeet white. Hindfeet long, with soles dark and naked; three median digits of similar length, Digit 1 short; rather long claws. Tail long (at least 125% of HB), covered by short hairs; long terminal pencil of darker hairs. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species Four species are similar in morphology and size: *T. arenarius*. Chromosome number: 2n = 30/31; Mauritania only.

T. gracilis. Chromosome number: $2n = 36/37$; widely distributed in West Africa.

T. petteri. Chromosome number: $2n = 18/19$; Mali, Niger and Burkina mostly south of Niger R.

T. pygargus. Chromosome number: $2n = 22/23$; Senegal and Niger.

Distribution Endemic to Africa. Sahel Savanna BZ. Only known from W Mali (Dilly, $15^{\circ}01'N$, $7^{\circ}40'W$) and S Mauritania (Chalkha, $16^{\circ}40'N$, $9^{\circ}18'W$).

Habitat Sandy-clay soil in a millet field surrounded by degraded savanna (Mali), and amongst thorny bushes in fallow land densely covered by grasses (Mauritania) (Dobigny *et al.* 2003).

Abundance No information.

Remarks Syntopic with *Gerbillus nigeriae* and *G. nancillus* (Dobigny *et al.* 2003) in Mali.

Conservation IUCN Category: Least Concern.

Gauthier Dobigny & Laurent Granjon

Subfamily LEIMACOMYINAE – Büttner's Forest Mouse

Leimacomyinae Musser & Carleton, 2005. *In*: Mammal Species of the World, 3rd edn, p. 1246.

The subfamily is based on a single genus and species, *Leimacomys buettneri*, documented only from the 'high-forest belt' in Togo (Rosevear 1969; see also species profile). It has been unrecorded since the first two specimens were collected in 1890 and is believed extinct by some (see review in Grubb *et al.* 1998). Nothing is known of its habitat or habits, although it is thought to be insectivorous and presumably terrestrial (see species profile). The species may also occur in Ghana, since the type locality is close to the Ghana–Togo border (Grubb *et al.* 1998). Focused surveys of long duration, which emphasize techniques for collecting small insectivores, should be conducted in the forests of Togo and nearby Ghana to assess the status of this unique rodent.

Leimacomys is small, with small, densely haired pinnae and an extremely short naked tail. The wide and moderately long rostrum, slight supraorbital ridges and broad braincase contribute to the robustness of the skull (Rosevear 1969). The zygomatic arches are similarly stoutly constructed, with a broad zygomatic plate and pronounced dorsal notch. Other skull characters include: anterior palatal foramina narrow and long, extending posteriorly to the lingual root of first molars; bony palate wide and projecting well

behind third molars to form a prominent shelf; mesopterygoid fossa correspondingly short and wide; slender upper incisors pro-odont, with the anterior face possessing a shallow groove; and lower incisors very slender. The molars retain the primitive number of roots, and their occlusal surfaces are configured as simple laminae. The middle lamina on M^1 and anterior lamina on M^2 are composed of three cusps and appear chevron-shaped; cusps t1 and t7, longitudinal enamel crests and posterior cingulum are absent from upper molars; upper third molars are moderately reduced compared with second molars (Misonne 1966, Dieterlen 1976c, Denys 1993, Denys *et al.* 1995) (Figure 58).

Following Matschie (1893), most systematists have regarded *Leimacomys* as an atypical member of Dendromurinae (G. M. Allen 1939, Rosevear 1969, Carleton & Musser 1984). Among dendromurines, its molar topography exhibits strongest similarity to *Steatomys* (Misonne 1966, Dieterlen 1976c). In another interpretation, Ellerman (1941) tentatively associated the genus with Murinae, an opinion followed by Simpson (1945). As emphasized by Denys (1993), little of the external and cranial morphology of *Leimacomys*, except for the molar patterns, suggests affinity with dendromurines

Figure 58. Skull and mandible of *Leimacomys buettneri* (after Misonne 1966 and Rosevear 1969).

proper. Instead, the conformation of the body and skull of *Leimacomys* resembles murine or deomyine rodents, and its cranial configuration is strikingly similar to the deomyine *Lophuromys*. Unlike murine and most deomyine rodents, however, the upper molars of *Leimacomys* lack a t1 cusp, a character common to those murid groups. Cladistic analysis, primarily using dental traits, has underscored the isolation of *Leimacomys* from dendromurines in the strict sense, and instead associated the genus in a lineage that also contains Gerbillinae and

Mystromyinae (Denys *et al.* 1995).

In view of its morphological and phylogenetic separation from dendromurines proper, Musser & Carleton (2005) placed *Leimacomys* in its own subfamily and provisionally consider it to be a cladistically primitive member of Muridae.

Guy G. Musser & Michael D. Carleton

GENUS *Leimacomys* Büttner's Forest Mouse

Leimacomys Matschie, 1893. Sber. Ges. Naturf. Freunde Berlin, p. 107. Type species: *Leimacomys buettneri* Matschie, 1893.

Leimacomys buettneri.

A monotypic genus known only from Togo in West Africa. This genus has had an interesting and controversial history (see details above). Musser & Carleton (2005) considered that *Leimacomys* is sufficiently different from the Dendromurinae to warrant placement in its own subfamily, Leimacomyinae, within the Muridae. *Leimacomys* could be the last existing element of a muroid lineage, isolated for a long time and endemic to the West African forest region. Rosevear (1969) provides a good discussion of the genus. Characteristics of the genus are given in the subfamily and species profiles. The single species in the genus is *Leimacomys buettneri*.

Fritz Dieterlen

Leimacomys buettneri BÜTTNER'S FOREST MOUSE (BÜTTNER'S TOGO MOUSE)

Fr. Souris sylvestre de Büttner; Ger. Büttners Togomaus

Leimacomys buettneri Matschie, 1893. Sber. Ges. Naturf. Freunde Berlin, p. 109. Bismarckburg, Togo (= near Yege, Togo). 710 m.

Taxonomy Only two specimens from the type locality are known, both collected in 1890 (see Rosevear 1969 and Dieterlen 1976c for comment). Both are preserved in alcohol: one is a flat skin and the other is a complete individual from which the skull and stomach have been extracted. Of the skulls, only one is extant and – due to mismatching – is composed of the mandible of one of the specimens (an old adult) and the cranium of the other (a young adult). From this, it is known that both specimens were adults. Dental characteristics suggest relationships to the Dendromurinae and not to the Murinae

(Misonne 1966). Because the species does not fit exactly into either of these subfamilies, Musser & Carleton (2005) place it by itself in a new subfamily, Leimacomyinae. Synonyms: none. Chromosome number: not known.

Description Small mouse with very short tail and pro-odont incisors. Dorsal pelage golden-brown; hairs grey at base, pale brown distally, with black tip; hairs up to 9.5 mm long. Paler on the flanks. Ventral pelage grey-brown. Ears with short hairs on outer and inner

sides. Forefeet with five digits; very long claws, except rudimentary Digit 1 of forefoot has a nail. The claws are relatively long, e.g. 2.1 mm on Digit 3 of forefoot, and 2.5 mm ($>10\%$ of HF) on Digit 3 of hindfoot; claws of hindfeet $>10\%$ of hindfoot. Tail short (ca. 30% of HB), mostly naked except for a few short bristles, tapering towards tip. Skull: incisors pro-odont, forming semicircle on cutting edge, single faint groove on anterior face of each incisor; interorbital constriction very conspicuous; slight supraorbital ridges; palate extends well posterior to the posterior end of cheekteeth (more so than in other murid rodents); M^1 and M^2 with lamina-like transverse rows; $t1$ on M^1 absent (Figure 58). The skull is similar in form to that of *Lophuromys* (due to convergence), although detailed structure suggests affinities to the Dendromurinae. (Description based on original description and on Rosevear 1969.)

Geographic Variation None recorded.

Similar Species

Steatomys spp. Similarly very short tail (ca. 50% of HB); four digits on forefoot; incisor teeth orthodont/opisthodont; zygomatic plate very small; zygomatic arches flared; palate short, not extending far behind the cheekteeth; tendency to become fat at certain times of year; widespread geographic distribution.

Distribution Endemic to Africa. Northern Rainforest–Savanna Mosaic. Recorded only from the type locality in Togo (see also below).

Habitat The type locality was described as in the ‘high forest belt’ (Rosevear 1969). However, the only known locality for this species is $08^{\circ}11'N$, $00^{\circ}41'E$, which is in the Rainforest–Savanna Mosaic where patches of riverine and relict forest alternate with grassland and woodland savanna. Rosevear also mentions that the generic name comes from the Greek *Lima* (garden or meadow) and *mys* (mouse), which suggests that the habitat may be dense grasslands close to riverine forest where the soil is moist and suitable for digging (see Remarks) – a habitat similar to that of *Lophuromys* spp.

Abundance Known only by the two type specimens.

Remarks Virtually nothing is known about this species. However, the morphology of the feet suggest that it is terrestrial and burrowing, and the very short tail suggests that it is not a climbing mouse like *Dendromus* spp. The single stomach was full of termites (Dieterlen 1976c). These limited observations suggest that it is an insectivore that probably gathers its prey by scratching in the soil and litter with its long claws – in much the same way as do *Lophuromys* spp.

Leimacomys buettneri

Conservation IUCN Category: Data Deficient.

Likely to be ‘Critically Endangered’ because of very limited range. No individuals of this species have been encountered since the type specimens were obtained more than 100 years ago. Two extensive surveys in Togo during the 1960s failed to find any evidence of this species, and none has been found in recent years. On this evidence, Schlitter (1989) considers it may be extinct.

Measurements

Leimacomys buettneri

*Formerly *Myomys*.

The Murinae forms the largest assemblage of species within either Muridae or the larger Muroidea and exhibits the most expansive geographic range. Totalling about 124 extant genera and 543 living species, the subfamily is indigenous to Eurasia, the Middle East, Arabian Peninsula, Indomalayan region, Japan, Ryukyu Islands, Philippine Islands, the numerous archipelagos stretching from the Sunda Shelf to the New Guinea and Australian region, and Africa (Musser & Carleton 2005). The subfamily is represented in Africa by 31 genera and 145 species. African endemics (27 genera, 139 species) comprise about 20% of all murine taxa. Most species of *Arvicanthis* and *Myomyscus* are also restricted to Africa, but a single species of each (*A. niloticus* and *M. yemeni*) is also found on the Arabian Peninsula. Of the 39 species of *Mus*, 17 (44%) are African endemics; some researchers view these sub-Saharan endemics, currently arranged as the subgenus *Nannomys*, as a separate evolutionary radiation that should be recognized as a genus. *Mus spretus* (subgenus *Mus*), native to the western Mediterranean region of south-western Europe, also occurs in the Maghreb of North Africa where, judged by late Pleistocene samples, it may have originated (Dobson 1998, 2000). Two genera, *Apodemus* and *Nesokia*, have large geographic

ranges outside of Africa and only marginal distributions on the continent. *Apodemus sylvaticus*, one of the 20 Palearctic species of *Apodemus*, reaches the Mediterranean fringe of North Africa (Kock & Felten 1980), which may represent an accidental introduction by humans followed by subsequent spread throughout Mediterranean coastal habitats (Dobson 1998, 2000, Michaux *et al.* 2002). *Nesokia indica*, indigenous to western Asia, the Middle East and the Arabian Peninsula, also occurs in north-eastern Egypt, and Pleistocene fossils from Egypt and northern Sudan point to a formerly broader African distribution (Osborn & Helmy 1980).

Three non-native murines – *Mus musculus*, *Rattus norvegicus* and *R. rattus* – have invaded parts of the continent, but have not been able to invade natural communities. They are mostly restricted to humanized environments such as cities, towns, villages and food stores. Although their initial evolution and original distribution are rooted in Eurasia, they are now found in many parts of the world and are members of a small cluster of murines (four genera and 14 species, possibly including *Apodemus sylvaticus*; see above) that have expanded their distributions far from their natural ranges through intentional or accidental processes associated with human migration and settlement (Musser & Carleton 2005). Also, the Indomalayan *Bandicota bengalensis* was introduced to Patta Island, Kenya, but whether a population became established is unknown (Corbet & Hill 1992). No other subfamily of Muroidea, or even Rodentia, has such a relatively large contingent of species whose present geographic distributions have been mediated by anthropogenic activities.

Living native African murines range in body size from small (e.g. most species of *Mus*) to large (e.g. some species of *Arvicanthis* and *Aethomys*). No endemic very large-bodied or giant murines are present. Variation in body form reflects terrestrial (e.g. *Arvicanthis*), scansorial (e.g. *Hylomyscus*), arboreal (e.g. *Thallomys*) and limnetic (e.g. *Colomys*) adaptations. Although some species may excavate burrows or shallow places to nest, none exhibits the morphological and physiological adaptations associated with muroids that are extremely fossorial (e.g. *Tachyoryctes* and *Spalax* in Spalacidae). Most African murines are nocturnal, some are diurnal; and they fill a variety of trophic niches, from omnivorous, herbivorous and granivorous to insectivorous and carnivorous. The bulk of endemic murine species occurs in the sub-Saharan biotic zones, inhabiting deserts, grasslands, savannas, rainforests and afro-montane forests. Only three genera of typically sub-Saharan murine rodents are represented in Africa north of the Sahara: *Lemniscomys barbarus* (a Maghreb endemic), *Mastomys erythroleucus* (primarily sub-Saharan with an isolated population in west-central Morocco) and *Arvicanthis niloticus* (also primarily sub-Saharan with populations in Egypt and Sudan; Musser & Carleton 2005).

The Murinae is characterized by a cohesive suite of morphological traits (Carleton & Musser 1984), but derived molar conditions form the cardinal basis for defining the subfamily. Two neomorphic cusps, the anterostyle (t1) and enterostyle (t4), are present on the lingual border of the upper first molar and form two chevron-shaped, transverse lamina; both upper and lower molars lack longitudinal enamel crests between lamina; and cusps on the lower molars are positioned opposite one another (Flynn *et al.* 1985, Jacobs *et al.* 1989,

Freudenthal & Martin Suárez 1999). Other derived cranial features include their modified carotid circulatory pattern (sphenofrontal foramen and squamosal-alisphenoid groove absent; stapedia foramen present) and a reduced tegmen tympani that does not contact the posterior squamosal (Bugge 1970, Carleton & Musser 1984 and unpubl.). The monophyly of Murinae is additionally supported by phylogenetic analyses of mitochondrial and nuclear genes (e.g. Verneau *et al.* 1997, 1998, Michaux *et al.* 2001, Debry 2003, Jansa & Weksler 2004), although the number of genera sampled to date is relatively few and in some studies includes only *Mus* and *Rattus*. Such studies identify Gerbillinae and Deomyinae as the closest relatives of Murinae (Martin *et al.* 2000, Michaux *et al.* 2001, Adkins *et al.* 2003, Jansa & Weksler 2004). The three subfamilies may have diverged from an ancestral muroid stock about 20.8–17.9 mya (early Miocene), an estimate derived from molecular-clock assumptions (Michaux *et al.* 2001). By late Miocene, but not earlier, representatives of each subfamily are recorded from African sediments (Jaeger 1977b, Mein *et al.* 1993, Geraads 2001, Winkler 2001).

While recognition of Murinae as a natural group is strongly supported, uncertainty over relationships among endemic African murines has produced two viewpoints to explain their diversity. Employing microcomplement fixation of albumin, Watts & Baverstock (1995a) identified an African murine clade separate from New Guinean, Australasian and South-East Asian evolutionary lineages, and suggested that living African murines represent ‘a period of rapid radiation from a single ancestor, beginning 8–10 mya and still continuing’. Mitochondrial and nuclear gene sequences have disclosed a large African murine clade (*Aethomys*, *Arvicanthis*, *Dasymys*, *Desmomyss*, *Grammomys*, *Hybomys*, *Lemniscomys*, *Mylomys*, *Pelomys* and *Rhabdomys*) that partly accords with the phylogenetic grouping identified by Watts and Baverstock (Ducroz *et al.* 2001). The alternate view, that living African

murines represent a paraphyletic assemblage, draws support from DNA/DNA hybridization (Chevret 1994) and from other gene-sequence analyses (Lecompte 2003, Jansa & Weksler 2004). In addition to an *Arvicanthis* clade (containing the same genera as given by Ducroz *et al.* 2001), Lecompte identified *Praomys* (*Colomys*, *Heimyscus*, *Hylomyscus*, *Mastomys*, *Myomyscus*, *Praomys*, *Stenocephalemys*, and *Zelotomys*), *Mus* (species in *Nannomys*) and *Malacomys* (containing only species of *Malacomys*) lineages, all three distantly isolated from the *Arvicanthis* clade and from each other.

The meagre number of Miocene taxa recovered from African sediments offer no resolution to whether the derivation of modern African murines is from a single ancestral group or from several ancestral groups, or to their origin as a result of one or more immigrations. Southern Asia is vaguely mentioned as the source area, with arrivals in Africa occurring in middle to late Miocene–Pliocene (Jacobs 1985, Winkler 1994, 2002). Late Miocene is the earliest documentation for *Progonomys* and *Paraethomys* in North Africa (Jaeger 1977b, Mein *et al.* 1993) and for *Karnimata* and *Saidomys* in Kenya (Winkler 2001). Murines from earlier Miocene strata are known only from northern Pakistan, including the middle Miocene *Antemus*, generally considered the earliest murine (Jacobs & Downs 1994, Freudenthal & Martin Suarez 1999). Fossils of living endemic African murines first appear in the Pliocene (Denys 1999, Winkler 2002). Although now largely confined to Africa, *Mastomys* and *Arvicanthis* are each extraliminally represented by a single species, now extinct, that lived in Israel during the Pleistocene (Tchernov 1968, 1996), and by an extinct Pliocene species on the Mediterranean island of Rhodes (De Bruijn *et al.* 1996).

The subfamily is currently represented in Africa by 31 genera.

Guy G. Musser & Michael D. Carleton

GENUS *Aethomys*

Veld Rats

Aethomys Thomas, 1915. Ann. Mag. Nat. Hist., ser. 8, 16: 477. Type species: *Epimys hindei* Thomas, 1902.

The genus *Aethomys* currently includes 11 species (Table 29), of which ten are endemic to East, central and southern Africa, and one species is endemic to West Africa (Musser & Carleton 1993, Chimimba 1998, Chimimba *et al.* 1999). An additional proposed species (*A.*

Aethomys kaiseri.

halleri) (see Denys & Tranier 1992) requires assessment. Species in the genus occur in a variety of savanna woodland and grassland habitats, preferring those that include shrubs or thick grass, hollow tree trunks and logs, creviced rocky areas, and/or termitaria. Some species may occur commensally with humans in agricultural areas. Although some are widely distributed (e.g. *A. chrysophilus*), others are restricted (e.g. *A. stannarius*, *A. silindensis*).

Veld Rats are generalized medium- to large-sized murid rodents. Species in the genus vary in body size, body proportions and pelage colour. The genus is most similar to *Rattus*, from which it differs in having molars that are clearly cuspidate and anterior palatal foramina that extend posteriorly to between the molars (Figure 59). Although generally considered ‘long-tailed’, tail length varies among species (ca. 70–150% of head and body length). Pelage is short, sleek or rough, and the dorsal pelage is often ‘sunburnt’ (hence the Greek-derived generic name: *eithos* = sunburnt; *mys* = mouse) in various shades of brown, grey, red and yellow. The hairs of the ventral pelage may be completely white, or grey at base with a white tip. Limbs are equal in size, the feet usually white above. Forefoot has four digits

Table 29. Species in the genus *Aethomys*. Arranged in order of increasing mean head and body length.
(n. d. = no data.)

| Species | HB mean (mm) | T mean (mm) [% of HB] | Dorsal pelage | GLS mean (mm) | Chromosome number | Width M' | Nipples | Notes |
|------------------------|------------------------|-----------------------------------|------------------------------------|---------------|-------------------|----------|------------|---|
| <i>A. granti</i> | 111 | 117 [97–113%] | Dull yellowish-brown to dark brown | 30.0 | 2n = 32 | n. d. | 3 + 2 = 10 | South Africa |

| <i>A. bocagei</i> | 165 (♂ ♂)
143 (♀ ♀) | 189 (♂ ♂),
160 (♀ ♀)
[115%] | Pale brown | 40.9 | 2n = 50 | n. d. | 0 + 2 = 4 | W and C Angola, SW DR Congo |
| <i>A. silindensis</i> | 173 | 177 [92–114%] | Buffy-brown, black tips | 40.4 | n. d. | 2.2–2.3 | n. d. | E Zimbabwe |

(Digit 1 absent); hindfeet have five digits (Digits 1 and 5 are very small and do not reach to base of Digits 3, 4 and 5). The tail may appear naked, but has a sparse to moderate covering of short hairs. Females have four to six nipples.

Members of the genus are nocturnal and terrestrial, but some may be slightly arboreal. All species with known food habits are omnivorous, mostly feeding on grass, foliage, fruits and seeds, and occasionally on invertebrates. Nests are constructed from accumulations of grass, twigs and debris. Social behaviour is highly variable. Wild populations of some species may be composed of widely spaced, territorial pairs (e.g. *A. chrysophilus*), but others may include small groups nesting communally (e.g. *A. nyikae*). In some cases, confinement to limited habitat patches may give an erroneous impression of communal social behaviour. Population sizes are variable, especially in unpredictable environments. At high densities, some species may facilitate transmission of human diseases, as well as causing extensive damage to crops and stored grain.

Breeding patterns vary geographically, with some species breeding throughout the year, sometimes with summer peaks, while others show no evidence of breeding during colder, drier months (Skinner & Smithers 1990). Gestation: 21–31 days. Litter-size: 2–4. Females may have a postpartum oestrus. Nipple-clinging by young occurs in all species studied.

Although fossil remains are limited, records include *A. lavocati* and *A. deheinzeli* from the Pliocene and Pleistocene of East Africa, and *A. modernis* and *A. adamanticola* from Pliocene–late Pleistocene of South

Figure 59. Skull and mandible of *Aethomys chrysophilus* (HC 2809).

Africa and the Pleistocene of Namibia (Wesselman 1984, Black & Krishtalka 1986, Denys 1990c). It is speculated that *A. adamanticola* may represent an advanced stage of an early Miocene lineage closely related to the genus *Dasymys*, but not ancestral to it. There is no indication of a close relationship between the East African and southern African fossil species, precluding speculation on the origin and time of divergence of the genus (Denys 1990c).

The taxonomic placement of *Aethomys* relative to other murid genera has a complex nomenclatural history as reflected by some currently recognized species within the genus that originally were ascribed to *Gerbillus*, *Praomys*, *Mus* and *Epimys* (De Graaff 1981). Particularly problematic is the relationship with *Rattus*. Thomas (1915a, b) for example, variously considered *Aethomys* as a subgenus of *Rattus* or as a full genus. Support for generic status is based on dental and karyological characters (Ellerman *et al.* 1953, Matthey 1964, Davis 1975b). Similarly, little is known about evolutionary relationships among the 11 currently recognized species of *Aethomys* (Musser & Carleton 1993, Chimimba 1998, Chimimba *et al.* 1999). No study has considered all these species simultaneously; previously postulated relationships were based largely on comparisons that were biogeographically restricted and involved only a few species (e.g. Musser & Carleton 1993). Other relationships have been inferred from previous taxonomic treatments (e.g. Ellerman 1941, Swynnerton & Hayman 1950, Rosevear 1969, Davis 1975b, Delany 1975, Ansell 1978, Hutterer & Joger 1982, Crawford-Cabral 1998, 1999).

The genus may be subdivided into two subgenera: *Micaelamys* (*A. granti* and *A. namaquensis*) and *Aethomys* (the remaining nine species). These subgenera exhibit distinct modes of karyotypic change and differences in gross sperm and bacular morphology (Visser & Robinson 1986, 1987). Other distinguishing characters include a more robust skull form with more prominent cranial sutures in members of the subgenus *Aethomys*, a well-developed anterior median cusp on the first upper molar in members of the subgenus *Micaelamys*, and differences in general body and cranial size. However, immunological (Watts & Baverstock 1995b) and molecular data (Ducroz *et al.* 2001, Castiglia *et al.* 2003, Russo 2003), as well as cladistic analyses of qualitative cranial data (Chimimba 2005) strongly suggest that the genus is paraphyletic and hence the taxonomic elevation of the currently recognized subgenera to full generic rank. This paraphyly and the differences outlined above led Skinner & Chimimba (2005) to recognize *Aethomys* and *Micaelamys* as two distinct genera.

The species of *Aethomys* are distinguished by differences in general body size, pelage colouration and texture, tail length relative to head and body length, molar cusp pattern and number of molar roots. Other distinguishing characters include haemoglobin protein electromorphs, DNA sequences, sperm and bacular morphology, chromosome number and number of nipples.

Aethomys bocagei BOCAGE'S VELD RAT (BOCAGE'S AETHOMYS)

Fr. Rat des rochers de Bocage; Ger. Bocages Veld-Ratte

Aethomys bocagei (Thomas, 1904). Ann. Mag. Nat. Hist., ser. 7, 13: 416. Pungo Andongo, Angola.

Taxonomy Originally described as *Mus bocagei* but subsequently re-assigned to *Aethomys*. Regarded as a valid species by Hill & Carter (1941), Davis (1975b), Musser & Carleton (1993) and Crawford-Cabral (1998, 1999). Synonyms: none. Chromosome number: $2n = 50$ (Matthey 1963a).

Description Large rodent. Dorsal pelage generally pale brown, resulting from a mixture of blackish and clay hairs. Flanks grey. Ventral pelage white; hairs slate-grey at base, with white tip. Ears medium-sized, brown. Fore- and hindfeet with pure white upper surface. Tail very long (ca. 115% of HB), uniformly brown, coarsely scaled, naked with sparse fine hairs. Males usually larger than ♀♀. Nipples: $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species

- A. silindensis*. Similar in cranial, dental and external characters; molars moderately broad (M^1 : 2.2–2.3 mm); E Zimbabwe only.
- A. namaquensis*. Smaller (means HB: 113 mm, T: 154 mm, HF: 26 mm, but tail relatively longer (140% of HB); chromosome number: $2n = 24$; narrowly sympatric in southern part of range.
- A. thomasi*. Similar HB length (mean 150 mm); shorter tail (mean 125 mm, ca. 83% of HB); shorter HF (mean ca. 29 mm); narrowly sympatric in southern part of range.

Distribution Endemic to Africa. Zambezan Woodland BZ. Recorded only from W and C Angola and extreme SW DR Congo. Distribution limits unknown, but speculated to occur throughout NW Angola, and possibly W DR Congo and SW DR Congo (Hill & Carter 1941, Musser & Carleton 1993, Crawford-Cabral 1998, 1999).

Habitat Mostly associated with savanna interspersed with rainforest (Crawford-Cabral 1998). Type specimen was collected at 1200 m.

Abundance Uncertain, but probably common.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Status needs further evaluation.

Measurements

Aethomys bocagei

Aethomys chrysophilus RED VELD RAT (RED AETHOMYS)

Fr. Rat des rochers roux; Ger. Rote Veld-Ratte

Aethomys chrysophilus (de Winton, 1897). Proc. Zool. Soc. Lond. 1896: 801 (publ. 1897). Mazoe, Mashonaland, Zimbabwe.

Taxonomy Originally described in the genus *Mus*. *Aethomys chrysophilus*, originally considered to be a single species, is now known to consist of two cytogenetically distinct sibling species, *A. chrysophilus* and *A. ineptus* (Chimimba *et al.* 1999). *Aethomys chrysophilus* (*sensu stricto*) is characterized by a karyotype of $2n = 50$ and sperm morphology typical of rodents (Gordon & Watson 1986, Breed *et al.* 1988). In contrast, *A. ineptus* has a karyotype of $2n = 44$ and a spatulate sperm structure (see *A. ineptus*). Because *A. chrysophilus* and *A. ineptus* cannot be distinguished externally, information included in this account is either based on positively identified specimens or on specimens whose identity can be inferred from their locality of collection (Linzey *et al.* 2003). Synonyms: *acticola*, *alticola*, *imago*, *singidae*, *voi*. Subspecies: none. Chromosome number: $2n = 50$.

Description Medium-sized robust rodent. Dorsal pelage reddish-brown mixed with black or brownish-black hairs. Variation in dorsal pelage due to concentration of dark hairs, leading to pelage being variously described as brown, orange-yellow, or cinnamon. Ventral pelage white; hairs white or white with grey base. Dorsal and ventral colouration sharply delineated. Upper surface of feet covered with white or pale yellow-orange hairs. Soles of hindfeet dusky. Tail longer than HB (ca. 120%), sparsely haired and coarsely scaled. Skull: mean 36.1 mm and relatively narrow, with greatest width <51% of greatest length; molars narrow ($M^1 < 2.0$ mm); incisors opisthodont. Nipples: $1 + 2 = 6$.

Geographic Variation Studies are needed to resolve significance of geographic variation within a newly defined geographic range that now excludes *A. ineptus*.

Similar Species

- A. ineptus*. May co-exist with *A. chrysophilus*, but there are no distinguishing external features.
- A. namaquensis*. Similar in appearance and frequently occurring in same habitats; adults generally smaller and more delicate (greatest length of skull <35 mm); tail relatively longer (135% of HB); hindfeet on average smaller.
- A. kaiseri*. Ventral pelage greyer; skull relatively wider (greatest width >55% of greatest length), molars wider ($M^1 > 3.2$ mm); incisors orthodont.
- A. nyikae*. Tail relatively shorter (95–115% of HB); molars wider ($M^1 2.0$ – 2.2 mm); incisors orthodont.

Distribution Endemic to Africa. Zambezi Woodland BZ, part of Sahara Arid BZ (Kalahari Desert) and southern part of Somalia–Masai Bushland BZ. Widespread in East, central and southern Africa. Recorded from SE Kenya southward and westward through Tanzania, Zambia, Angola, Malawi, Zimbabwe, N Mozambique and the Limpopo Valley of N South Africa to approximately 24° S (Linzey *et al.* 2003). Specimens from S Mozambique, N and E Botswana and N Namibia have not been positively identified. Ranges of *A. chrysophilus* and *A. ineptus* essentially parapatric, with the only area of significant overlap in the region west of Pretoria, South Africa. Known to co-occur only at one site (Limpopo Province, South Africa), although

*Aethomys chrysophilus*

co-occurrence likely at other sites in region of parapatry. Range in South Africa generally corresponds with distribution of mopane (*Colophospermum mopane*) and baobab (*Adansonia digitata*) trees.

Habitat A habitat generalist that occupies a variety of savanna-woodland habitats. Described as ubiquitous in many regions, but prefers abundant cover in the form of rocks, logs, thorn fences around agricultural plots, termitaria and/or heavy grass. Frequently found on kopjes in association with *A. namaquensis*, but appears to reach higher densities in habitats where *A. namaquensis* is absent.

Abundance Based on studies in Malawi, Zimbabwe, Mozambique and South Africa, generally occurs at low densities (<8/ha) (Gliwicz 1985, Happold & Happold 1990, Linzey & Kesner 1997a, b, A. Linzey and M. Kesner unpubl.). However, higher densities occur locally (A. Linzey & M. Kesner unpubl.).

Adaptations Nocturnal and terrestrial, but climbs trees occasionally. Excavates burrows under bushes, rocks, logs, or tree roots, or uses crevices in rocks or holes in termite mounds.

Foraging and Food Omnivorous, with average diet consisting of 25% insects, 40% seeds and 35% vegetation (Gliwicz 1987). Greater dependence on seeds in the dry season (10% insects, 75% seeds, 15% vegetation).

Social and Reproductive Behaviour Pairs widely spaced, with rarely more than two adults occupying a burrow or crevice (Choate

1972). In captivity, individuals aggressive toward conspecifics, but when groups are together for long periods, development of social ranking reduces overt aggression. Both sexes build nests in captivity, but females with young sometimes exclude males from the nest.

Reproduction and Population Structure Reproduction occurs throughout the year but most births recorded in late dry season and early wet season (Hanney 1965, Brooks 1972, Hubbard 1972, Gliwicz 1985, Happold & Happold 1990, Neal 1990). Gestation: minimally 26 days, but up to 31 days if female lactating. Litter-size: 3–4 (1–6). At birth, young altricial, weight ca. 4.5 g. Eyes open Day 10–14. Weaning Day 26–33. Nipple-clinging until ca. Week 3. Minimum age at sexual maturity in ♀♀ (in captivity): 82 days. Age classes defined by weights as follows: >63 g adult ♀, 31–63 g subadult ♀, <31 g juvenile ♀, >71 g adult ♂, 31–71 g subadult ♂, <31 g juvenile ♂ (Bowland & Perrin 1988).

Annual variation in population density, with higher numbers in Sep–Mar in Malawi (Happold & Happold 1990) and May–Aug in Zimbabwe (Linzey & Kesner 1997a). In late dry season, populations are composed of proportionally large numbers of subadult individuals probably born during the previous wet season. Turnover rate in natural populations high, with 50% chance of survival to one month, 30% to two months and 23% to three months. Interannual fluctuations in numbers associated with variations in annual precipitation.

Predators, Parasites and Diseases Parasites include lice, fleas, ticks, nematodes and tapeworms. Diseased livers observed in 10% of animals examined in Malawi (Hanney 1965). Known to be a carrier of plague.

Conservation IUCN Category: Least Concern.

***Aethomys granti* GRANT'S VELD RAT (GRANT'S AETHOMYS)**

Fr. Rat des rochers de Grant; Ger. Grants Veld-Ratte

Aethomys granti (Wroughton, 1908). Ann. Mag. Nat. Hist., ser. 8, 1: 257. Deelfontein, north of Richmond, Cape Province, South Africa.

Taxonomy Originally allocated to the genus *Mus* but subsequently variously placed in *Myomys* (= *Praomys*) (Allen 1939), *Mastomys* (Roberts 1951), *Rattus* (subgenus *Micaelamys*; Ellerman 1941) and *Aethomys* (subgenus *Micaelamys*; Davis 1975b, De Graaff 1981, Meester *et al.* 1986, Musser & Carleton 1993). Determined to be a valid species, based on qualitative and quantitative morphological data, by Chimimba (1998) and Chimimba *et al.* (1999). Following Chimimba (2005), Musser & Carleton (2005) refer *granti* to the genus *Micaelamys*. Synonyms: none. Chromosome number: $2n = 32$ (Matthey 1964, Misonne 1974, Visser & Robinson 1986).

Description Small yellowish-brown or dark brown rodent. Dorsal pelage dull yellowish-brown or dark brown, hairs brownish-grey at base, grey or greyish-white at tip. Ventral pelage pale grey or greyish-yellow; hairs grey at base and grey or greyish-white at tip. Hairs slender, shallowly grooved and characteristically covered with petal-shaped scales (Keogh 1985). Tail long (ca. 97–113% of HB), brownish-black or dark reddish-brown; reasonably well haired with dark-coloured bristles that are longer and denser at the tip (Chimimba 1998, Chimimba *et al.* 1999). Lower jaw with anterior and posterior borders of ascending ramus parallel to each other. Skull: incisors moderately opisthodont; anterior palatal foramina extends to the second root of the M^1 . Nipples: $3 + 2 = 10$.

Geographic Variation Skull size shows a south-westerly–north-easterly clinal pattern of variation, in which overall cranial size is negatively correlated with longitude, and positively correlated with latitude; thus, specimens with the smallest skulls are found in the south-west of the geographic range and the largest in the north-east of the geographic range (Chimimba *et al.* 1998).

Similar Species

A. namaquensis. Tail longer relative to head and body; pelage harsher; hairs broad and covered with cup-shaped scales; anterior palatal foramina extends to the first root of M^1 (Keogh 1985, Skinner & Smithers 1990); lower jaw with anterior and posterior borders of ascending ramus not parallel to each other (Chimimba 1998).

Distribution Endemic to Africa. South-West Arid BZ (Karoo) and northern fringes of South-West Cape BZ. Recorded in parts of Northern, Western and Eastern Cape Provinces of South Africa.

Habitat Prefers rocky terrain, where it may co-occur with *Aethomys namaquensis* (Skinner & Smithers 1990). Found in fynbos, succulent karoo and nama-karoo biomes (Mugo *et al.* 1995).

*Aethomys granti*

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Aethomys hindei HINDE'S VELD RAT (HINDE'S AETHOMYS)

Fr. Rat des rochers de Hinde; Ger. Hinde's Veld-Ratte

Aethomys hindei (Thomas, 1902). Ann. Mag. Nat. Hist., ser. 7, 9: 218. Machakos, Kenya.

Taxonomy Originally described in the genus *Mus*. Originally considered a distinct species, but subsequently treated, in error, as a subspecies of *A. kaiseri* (e.g. Hollister 1919, Allen & Loveridge 1942, Swynnerton & Hayman 1951). Although noting that they were atypical, Hatt (1940a) assigned specimens of this species from NE Congo (= DR Congo) to *A. kaiseri medicatus*. Possibly *A. hindei* consists of a complex of species or subspecies (Denys & Tranier 1992). Synonyms: *alghazal*, *centralis*, *helleri*, *medicatus*, *norae*. Subspecies: none. Chromosome number: $2n = 50$ (Matthey 1963a).

Description Large rodent. Pelage soft and moderately long (mid-dorsal hairs ca. 10 mm). Dorsal pelage medium brown; hairs grey with brown tip; some longer hairs pure black, especially on mid-dorsal line. Flanks paler with few black hairs; hairs grey with pale brown tip. Ventral pelage greyish-white; hairs pale grey on basal half, whitish on terminal half. Head similar to dorsal pelage, without any special markings. Chin, throat and chest similar to ventral pelage. Limbs short; hindlimbs with scattered white hairs on upper surface. Tail moderately long (ca. 70–110% of HB, see also below); dark brown to black; ringed with many small scales; appears naked, but with many very small bristles. Skull: zygomatic width <55% skull length; molars narrow ($M^1 < 2.2$ mm); incisor teeth opisthodont; auditory bullae: 7.03 mm (cf. *A. stannarius*). Sexual dimorphism in weight noted in Uganda (♂♂ heavier; Okia 1976). Nipples: not known.

Geographic Variation Systematic studies are needed to resolve the significance of considerable geographic variation in morphological traits. Tail length is longer, and length relative to HB is greater, in populations from Cameroon (mean 156 mm, ca. 100% of HB) than in populations from Kenya (130 [128–132] mm, ca. 85% of HB), although HB length is very similar. Relative tail length varies on either side of Rift Valley: e.g. east of Rift Valley, tail length is <95% (70–95%) of HB; and west of Rift Valley, tail length is >95% (95–110%) of HB. Cranial and dental traits (e.g. ratio of zygomatic width to skull length, interorbital constriction width, auditory bullae length, length of M^1 – M^3 , and molar dimensions and features) also vary geographically (Denys & Tranier 1992).

Similar Species

A. kaiseri. Skull relatively wider (zygomatic width >55% of length); molar teeth broader ($M^1 > 3.2$ mm); incisors orthodont; west of Rift Valley, tail shorter (<95% of HB) but east of Rift Valley, tail same relative length.

Distribution Endemic to Africa. Eastern parts of Guinea Savanna BZ and Northern Rainforest–Savanna Mosaic and parts of Somalia–Masai Bushland BZ. Widespread. Recorded from N Cameroon eastwards to S Chad, N DR Congo, S Sudan and SW Ethiopia, Uganda, Kenya and N Tanzania. Southern limit uncertain.

*Aethomys hindei*

Habitat Rocky areas, in dense grass and bush cover, where annual rainfall averages 600–1500 mm (Misonne & Verschuren 1966, Delany 1972, Hubbard 1972, Okia 1976). Sometimes occurs in disturbed forest with thick undergrowth, overgrazed bush, or cultivated lands (Delany 1972, Okia 1976, Canova & Fasola 2000). Also recorded on lower slopes of mountainous areas (<2000 m) where farmland and grassland penetrate montane forest (Misonne 1963, Clausnitzer & Kityo 2001). Type specimen was collected at 1645 m.

Abundance Common in suitable habitats. In disturbed forest in S Uganda, populations (measured by minimum number known to be alive) are high from Jan–May (4.5–22.6/ha) and in August (13.6/ha), and generally low in the remaining months (0.0–9.1/ha) (Okia 1976). In coastal Kenya, density recorded as 6 individuals/ha in overgrazed bush. Populations in Uganda showed three- to four-fold multi-annual fluctuations, even though there were no obvious differences in quantity or distribution of rainfall (Okia 1976).

Adaptations Nocturnal and diurnal; terrestrial. In coastal Kenya, activity (as assessed by trapping records) equally divided between night and day (Canova & Fasola 2000). In Uganda, home-range varies from 30 to 1600 m² (Okia 1976).

Foraging and Food No information for wild-living individuals. In captivity, feeds on grains, fruits, nuts and vegetables (Hubbard 1972).

Social and Reproductive Behaviour Nipple-clinging of neonates is commonly observed (Allen & Loveridge 1942, Hubbard 1972). Females construct globular grass nests (Hubbard 1972).

Reproduction and Population Structure Reproduction probably occurs throughout the year; most pregnancies recorded during the wet season and most young animals caught in drier seasons (Hubbard 1972, Okia 1976). Gestation: 24–25 days. Mean litter-size: 2.0 (1–4, mode 1 and 2, $n = 18$ litters; Uganda; Okia 1976). At birth, young altricial. Development rapid, especially while attached to nipples. At birth, young lightly furred on back, heavily furred by Day 10. Eyes open Day 14. First leave nest Day 15. Adult size attained ca. Day 45 (Hubbard 1972). Sex ratio (field-caught adults) is ca. 1 : 1 (Okia 1976).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Aethomys ineptus TETEVELD RAT (TETE AETHOMYS)

Fr. Rat des rochers de Tete; Ger. Tete Veld-Ratte

Aethomys ineptus (Thomas and Wroughton, 1908). Proc. Zool. Soc. Lond. 1908: 546. Tette (= Tete), Zambezi River, Mozambique.

Taxonomy Originally described as *Mus chrysophilus ineptus*. *Aethomys ineptus* is morphologically indistinguishable from *A. chrysophilus* but is characterized by chromosome number of $2n = 44$ and spatulate sperm structure unique among murid rodents (Gordon & Watson 1986, Breed *et al.* 1988). Although a chromosome number of $2n = 44$ has been described from Côte d'Ivoire (Matthey 1958), it is now recognized that this material originated in South Africa (Chimimba 1998). Because *A. ineptus* and *A. chrysophilus* cannot be distinguished externally, information included in this account is either based on karyotypically identified specimens or is inferred from the geographic range (Linzey *et al.* 2003). Synonyms: none. Chromosome number: $2n = 44$.

Description See *A. chrysophilus*.

Geographic Variation None recorded.

Similar Species

A. chrysophilus. Externally indistinguishable from *A. ineptus*; chromosome number: $2n = 50$; may co-occur with *A. ineptus* in some parts of geographic range.

A. namaquensis. Similar in appearance; adults generally smaller and more delicate (greatest length of skull <35 mm); tail relatively longer (135% of HB); hindfeet on average smaller; frequently occurs in same habitats.

Distribution Endemic to Africa. Parts of Highveld BZ, and adjacent areas of Afromontane–Afroalpine and Zambezi Woodland BZs. Distribution is narrower than for *A. chrysophilus*, and possibly

Aethomys ineptus

confined to South Africa; there are no positively identified specimens from S Mozambique, Botswana and Namibia. In NC South Africa, occurs mostly above 1000 m, but occurs at lower elevations at more southern latitudes. Reaches southern limit in KwaZulu–Natal Province at about 30° S, but absent south and west of 23° S and 23° E. In Kruger National Park, the ranges of *A. chrysophilus* and *A. ineptus*

meet between Olifants and Satara, a region marked by transition from mopane shrubveld to open savanna (Linzey *et al.* 2003).

Habitat Grasslands, shrubs and rocks, where there is thick ground cover (Monadjem 1999a, A. Linzey & M. Kesner unpubl.). Appears to have same habitat preferences as *A. chrysophilus*.

Abundance Generally occurs at low to moderate densities (up to 18/ha; Miller 1994, Monadjem & Perrin 1998, Ferreira & Van Aarde 1999). However, higher local densities have been recorded, e.g. 37/ha near Pietermaritzburg (A. Linzey & M. Kesner unpubl.). Annual variation in population density, with higher numbers in the winter dry season, have been recorded in South Africa (1.01/ha in January to 3.24/ha in July; Korn 1981).

Remarks Nocturnal, with greater activity early in the night (Perrin 1981). In NE South Africa, reproduction is seasonal and confined to the wet summer months when nutritional supplies are abundant (Muteka *et al.* 2006c). However, follicular development and the presence of corpora lutea in ♀♀ outside the breeding season suggests that spontaneous ovulation may occur (Muteka *et al.* 2006a). Males have a significantly higher testicular mass and testicular volume, and the diameter of the seminiferous tubules is larger, when individuals are artificially subjected to a long daylength, suggesting reproduction is partially controlled by photoperiodicity (Muteka *et al.* 2006b).

Omnivorous; diet approximately 37–58% vegetation, 33–58% seeds and 0–8% insects (Miller 1994, Monadjem 1997b). Home-range: 1500–3000 m² (Korn 1981).

Conservation IUCN Category: Least Concern.

Aethomys kaiseri KAISER'S VELD RAT (KAISER'S AETHOMYS)

Fr. Rat des rochers de Kaiser; Ger. Kaisers Veld-Ratte

Aethomys kaiseri (Noack, 1887). Zool. Jahrb. Syst. 2: 228. Mpala, Marungu, DR Congo.

Taxonomy Originally described in the genus *Epimys*. Currently considered a valid species by most taxonomic authorities. Previously considered to include the currently recognized and sympatric *A. hindei* as a subspecies (Hollister 1919, Swynnerton & Hayman 1951). Synonyms: *amalae*, *hintoni*, *manteufeli*, *pedester*, *turneri*, *vernayi*, *walambae*. Subspecies: none. Chromosome number: not known.

Description Medium-sized rodent with warm yellowish-brown pelage. Dorsal pelage yellowish-brown; hairs grey at base with ochre or brown tips; pure black hairs result in darker colour along mid-dorsal line. Flanks paler grading to yellowish-grey on lower flanks. Ventral pelage off-white; hairs grey on basal third. Head similar in colour to back; short black vibrissae. Ears darkly pigmented, with sparse dark brown hairs. Fore- and hindlimbs short, grey. Forefeet with four digits; hindfoot with five digits; all with claws. Tail moderately long (ca. 95% of HB), ringed with scales, with numerous very short bristles, brown above, pale below. Skull broad, with width >52% of length; molars broad (M¹ >3.2 mm); incisors opisthodont. Nipples: 0 + 2 = 4.

Geographic Variation Individuals from Uganda are larger in some body measurements than individuals from Zambia (see below). Geographical variation in relative tail length, e.g. tail 83% of HB in Zambia, and 94% of HB in Uganda (Delany & Neal 1966). The eastern-most population, isolated from the main geographic range

of the species, may be a separate subspecies, *A. k. vernayi* (Crawford-Cabral 1999). Analysis of intra-specific variation is required to evaluate the significance of regional morphological variation.

Similar Species

A. chrysophilus. Ventral pelage white with more grey; tail relatively longer (ca. 120% of HB); skull relatively narrower (zygomatic width <51% of length); molars narrower (M¹ <2.0 mm); incisors opisthodont.

A. nyikae. Tail relatively longer (95–115% of HB), more uniformly coloured; molars narrower (M¹ 2.0–2.2 mm); incisors orthodont.

A. hindei. Tail relatively longer west of Rift Valley (95–110% of HB), but not different east of Rift Valley; skull relatively narrower (zygomatic width <50% of length); molars narrower (M¹ <2.2 mm); incisors opisthodont.

Distribution Endemic to Africa. Northern part of Zambezi Woodland BZ extending marginally into surrounding areas. Recorded from SW Uganda, S Kenya, Tanzania, SE DR Congo, Malawi, Zambia and E Angola.

Habitat Savanna habitats with trees and shrubs (Delany 1964a, 1972, Delany & Neal 1966, Misonne & Verschuren 1966, Vesey-Fitzgerald 1966, Hubbard 1972, Cheeseman 1981). In Uganda, 93% of captures near shrubs in savanna. In Malawi, found in stream

valleys (where it co-existed with *A. chrysophilus*) (Hanney 1965), and also in woodlands where it inhabits anthills, montane forest edges at ca. 2120 m, and pine plantations (Ansell & Dowsett 1988).

Abundance Uncertain; appears to be less common than *A. chrysophilus*. Very rare in tropical grassland in Uganda (four individuals out of 349 rodents in 17 months; Cheeseman & Delany 1979).

Adaptations Terrestrial and nocturnal (Delany 1964a, Ansell & Dowsett 1988).

Foraging and Food Omnivorous, including both plant material and insects (n = 3, Hanney 1965).

Social and Reproductive Behaviour Females aggressive toward males after mating and while young are in the nest (Cheeseman 1981).

Reproduction and Population Structure Little known about reproduction in wild populations. In Uganda, pregnant ♀♀ in Oct, Nov, Jan and Apr; lactating ♀♀ in May, Jun and Nov, and several ♂♂ in reproductive condition in Jul (Southern & Hook 1963, Delany 1975). In Malawi, a ♀ collected in May was in reproductive condition and had produced at least two previous litters (Hanney 1965). Gestation: 26–28 days. Litter-size: 2.6 (1–4), n = 6 litters). Sex ratio at birth approximately 1:1. At birth, average WT = 6.1 g, ear pinnae usually unfolded and incisors erupted. Fully haired Day 3. Eyes open Day 8–10. Weaned Day 26. Average weight at weaning = 47.8 g. Young nipple-cling from birth to Day 12. A pair in captivity produced litters at intervals of 32, 40 and 37 days, indicating that mating does not always occur during postpartum oestrus (Cheeseman 1981).

Predators, Parasites and Diseases Little information. Known to harbour cutaneous *Leishmania*, which can be transmitted to humans (Githure *et al.* 1986).

Conservation IUCN Category: Least Concern.

Aethomys namaquensis NAMAQUA VELD RAT (NAMAQUA AETHOMYS)

Fr. Rat du rochers du Namaqua; Ger. Namaqua Veld-Ratte

Aethomys namaquensis (A. Smith, 1834). S. Afr. Quart. J. 2: 160. Namaqualand, Cape of Good Hope, Cape Province, South Africa.

Taxonomy Originally described in the genus *Gerbillus*. A revision of *Aethomys* confirmed *A. namaquensis* as a valid species (Chimimba 1998). Following Chimimba (2005), Musser & Carleton (2005) refer *namaquensis* to the genus *Micaelamys*. Synonyms: *alborarius*, *arborarius*, *auricomis*, *avarillus*, *avunculus*, *calarius*, *capensis*, *centralis*, *drakensbergi*, *epupae*, *grahami*, *klaverensis*, *lechochloides*, *lechocla*, *longicaudatus*, *monticularis*, *namibensis*,

phippsi, *siccatus*, *waterbergensis* (Musser & Carleton 1993, 2005, Chimimba 2001). Subspecies: four. Chromosome number: 2n = 24.

Description Small to medium-sized rat with very long tail. Dorsal pelage yellowish-brown to reddish-brown grizzled with black that fades laterally; hairs black at base and yellowish-reddish at tip.

Ventral pelage white to pale grey or pale yellow-orange; hairs grey at the base (variable), white at tip. Pelage varies both geographically and individually. Feet white dorsally and dusky ventrally. Tail very long (ca. 140% of HB), sparsely haired, coarsely scaled and uniformly brownish-black. Anterior palatal foramina extend to first root of M^1 . Lower molar row with three cusps in the anterior row, a feature otherwise found only in *A. granti* within the genus. Nipples: $1 + 2 = 6$.

Geographic Variation Four subspecies are recognized and can be identified only by multivariate analysis of skull, dental characters and distribution (Chimimba 2001).

A. n. namaquensis: Succulent Karoo, Fynbos and the southern coastal Savanna/Grassland region of Northern Cape, Western Cape, Eastern Cape, KwaZulu–Natal and eastern Mpumalanga Provinces of South Africa.

A. n. lehocla: Nama–Karoo biome of southern Namibia, South Africa (North–West, SW Limpopo and NW Mpumalanga Provinces).

A. n. alborarius: Savanna biome of SW Angola, N Namibia, Botswana, Zimbabwe, Limpopo and W Mpumalanga Provinces of South Africa, and C Mozambique.

A. n. monticularis: Grassland biome of Free State, N Eastern Cape and SW Mpumalanga Province of South Africa, and Lesotho.

Similar Species

A. silindensis. Larger (mean HB: 174 mm); tail length similar to HB; rare, occurring only in eastern highlands of Zimbabwe.

A. granti. Tail length similar to HB; occurs only in S Cape Province of South Africa.

A. chrysophilus and *A. ineptus*. Ventral pelage greyer; chromosome number: $2n = 50$ (*A. chrysophilus*) and $2n = 44$ (*A. ineptus*). In *A. chrysophilus* and *A. ineptus*, the tail is thicker with coarser scaling, and the relative length of the tail is marginally shorter (ca. 120% of HB). However, there is considerable overlap in these characters

and distinguishing larger individuals of *A. namaquensis* from smaller individuals of *A. chrysophilus* and *A. ineptus* is problematic. The best differentiating characters for field identification are size (*A. chrysophilus* and *A. ineptus* ca. 25 g heavier), ratio of T to HB length (*A. chrysophilus* and *A. ineptus* tail shorter relative to HB), and hindfoot length (*A. chrysophilus* and *A. ineptus* on average larger) (M. Kesner & A. Linzey unpubl.).

Distribution Endemic to Africa. South–West Arid (Kalahari and Namib Deserts, Karoo), South–West Cape BZ and Highveld BZ. Widespread in southern Africa south of ca. 15°S from SW Angola to C Mozambique, including Botswana, Namibia, Zimbabwe, S. Zambia and South Africa. Not recorded in parts of S Mozambique nor from more arid areas of the central Kalahari, Karoo and Namib. Most northerly record is at higher altitudes on Mt Mulanje, Malawi (Ansell & Dowsett 1988, Happold & Happold 1992).

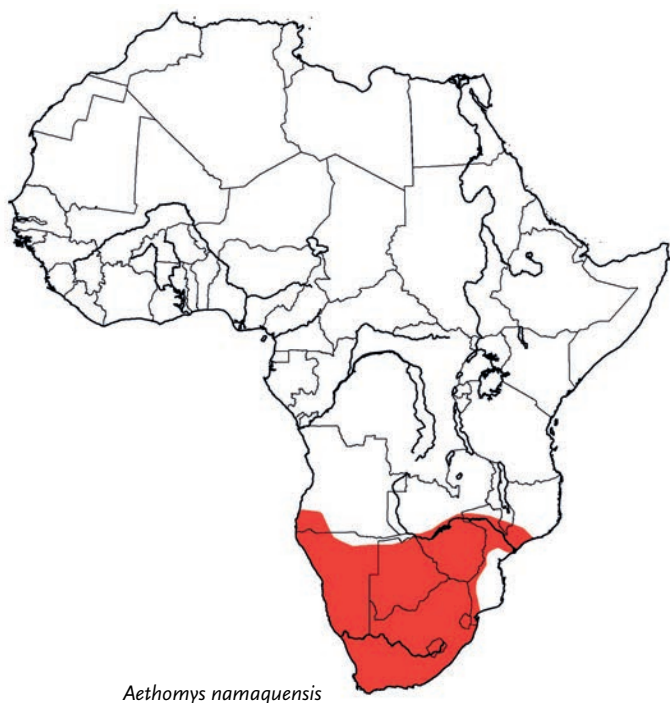

Habitat Savanna and semi-arid areas, often associated with rocky kopjes, outcrops or talus slopes dominated by medium-sized (10–20 cm) rocks. Also in adjacent non-rocky areas and occasionally in areas without rocks.

Abundance Common in suitable savannas, especially rocky habitats. Comprised 63–87% of the small mammal fauna in a talus slope habitat in W Zimbabwe (Linzey & Kesner 1997a) and the most common small mammal (38%) in rock-laden grassy slopes in N Mozambique (Gliwicz 1985). Density estimates vary geographically, seasonally and by habitat and include 2/ha (Succulent Karoo; Kerley & Erasmus 1992a), 5.4/ha (Namib; Withers 1979), 4–13/ha (Mozambique; Gliwicz 1985) and 5.2–27.3/ha (Zimbabwe; Linzey & Kesner 1997a). Biomass varies seasonally from 203 to 596 g/ha (Linzey & Kesner 1997b). Greatest numbers and biomass occurred in the early dry season of Zimbabwe and Mozambique.

Adaptations Terrestrial and semi-arboreal. Builds grass-stick nests in rock crevices and in upright or fallen hollow trees. In non-rocky habitats, grass-sticks are piled over the entrance to burrows under brush or other debris. Nocturnal, with slightly higher activity just after dusk and just before dawn. Well adapted to the large daily temperature fluctuations in rocky crevices or hollows of trees. Resting metabolic rate and thermal conductance is lower than expected, and hence individuals can exist for long periods without free water when on a low-fibre diet. However, Namaqua Rock Rats are restricted to more mesic parts of semi-arid habitats and are not as well-adapted to xeric conditions as gerbils (Buffenstein *et al.* 1985).

Foraging and Food Opportunistic. Diet is grass and foliage (60–90%), seeds (2–40%) and insects (0–8%) (Withers 1979, Gliwicz 1987, Kerley *et al.* 1990, Monadjem 1997b). The caecum is relatively large, a character found in other grass-eating herbivores (Perrin & Curtis 1980, Woodall & Mackie 1987).

Social and Reproductive Behaviour Reported as nesting singly, in pairs and small groups. For example, Choate (1972) found five nests with more than two adults, two nests with a pair, and one with a solitary individual. In captivity, adult σ σ are mutually

Aethomys namaquensis

intolerant and exhibited territorial behaviour (marking, aggression, etc.). Adult ♀♀ showed intolerance to other ♀♀. Aggression may lead to a more cooperative social structure once dominance relationships are established. In the Namib, residents had a clumped distribution while non-residents were randomly distributed (Withers 1979). Home-ranges of ♂♂ (n = 6) did not overlap with those of other ♂♂, and similarly for ♀♀ (n = 2), although there was overlap in the home-ranges of ♂♂ and ♀♀. Mean home-range: 3100 m². Withers (1979) documented a negative association between trap stations frequented by Namaqua Veld Rats and Western Rock Sengis (*Elephantulus rupestris*).

Laboratory observations suggest young are attached almost constantly to the nipples of their mother; however, ♀♀ are rarely trapped with young attached, suggesting ♀♀ do leave the young when foraging. Neal (1990 and citations therein) proposed that nipple-clinging might lessen predation in more exposed areas (rock crevices as opposed to burrows) if small litter-sizes allowed transport of the entire litter.

Reproduction and Population Structure In Mozambique, juveniles present from Jan to Apr (Gliwicz 1985) suggesting births from Dec to Mar–Apr. In Botswana, pregnant ♀♀ recorded in Sep–May, with probable peak of births in Mar and Apr (Smithers, 1983). In Zimbabwe, reproductive individuals recorded Sep–May with peak numbers toward the end of the wet season in Mar–Apr (M. Kesner & A. Linzey unpubl.). In South Africa, reproduction is seasonal and confined to the wet summer months when nutritional supplies are abundant (Muteka *et al.* 2006a). Males have a significantly higher testosterone concentration when artificially subjected to a long daylength, suggesting reproduction is partially controlled by photoperiodicity (Muteka *et al.* 2006b). Gestation: greater than 22 days. Litter-size is rather similar throughout geographic range: 3.3 (1–5, n = 43; Transvaal, Rautenbach 1982), 3.1 (2–7, n = 42; Botswana, Smithers 1983) and 3.4 (S.D. = 0.16, n = 53; Zimbabwe, Neal 1990). Birth-weight: 2.5 g. Young altricial. Nipple-cling to mother until Day 16–21. Growth rate 0.45 g/day. Eyes open Day 10–12. Weaned Day 21–26, when WT 10–15 g (Neal 1990).

Population structure in Mozambique varied during the year (Gliwicz 1985). In Oct, at the end of the dry season, populations consisted of 40% juveniles (molars not completely erupted) and 60% adults (molars fully erupted and worn). Reproduction commenced after Oct; by Jan (peak of the wet season), population structure was 15% juveniles, 30% subadults (molars erupted but unworn) and 55% adults. By Apr (beginning of the dry season), all juveniles had grown to subadults and population structure was 0% juveniles, 50% subadults and 50% adults. In Jul, population structure was 65% subadults and 35% adults. No data for Aug and Sep. Withers (1979)

found mean survival for four two-month periods was 0.57 (n = 27) in the Namib. In Zimbabwe, mean one-month survival over a 15-month study was 0.81 (SE = 0.05, n = 51) yielding an estimated two-month survival of 0.65 (M. Kesner & A. Linzey unpubl.).

In the Namib, Withers (1979) concluded that ♂♂ and ♀♀ occurred in equal proportions (n = 27). Preliminary data from other localities suggest either equality or a bias toward ♂♂: e.g. 1 ♂ : 1.19 ♀♀ (Limpopo Province, South Africa, n = 52), 1 ♂ : 0.65 ♀♀ (W Zimbabwe, n = 32) and 1 ♂ : 0.37 ♀♀ (North-West Province, South Africa, n = 35) (♂ : ♀ estimates adjusted for differential probability of capture: M. Kesner & A. Linzey unpubl.).

Predators, Parasites and Diseases Known to carry mites, ticks, fleas, various internal nematodes and cestodes. Reported to be a reservoir for Rift Valley fever virus but unlikely to be a major host. Gill *et al.* (1987) sampled throughout the Northern Cape and North-West Provinces of South Africa and found that Namaqua Rock Rats had the highest prevalence of plague antibody (3.5%, n = 170) of any small mammal in the study. They suggest Namaqua Rock Rats (with other murid rodents) may be as important as gerbils in maintaining the plague.

Conservation IUCN Category: Least Concern.

Aethomys nyikae NYIKA VELD RAT (NYIKA AETHOMYS)

Fr. Rat des rochers de Nyika; Ger. Nyika Veld-Ratte

Aethomys nyikae (Thomas, 1897). Proc. Zool. Soc. Lond. 1897: 431. Nyika Plateau, Malawi.

Taxonomy Originally described in the genus *Mus*. Considered to be a synonym of *A. kaiseri* by Delany (1975) and a synonym of *A. chrysophilus* by Hanney (1965), but accepted as a valid species

by most authors (Ellerman *et al.* 1953, Davis 1975b, Ansell 1978, Musser & Carleton 1993). Synonyms: *dollmani*. Subspecies: none. Chromosome number: not known.

*Aethomys nyikae*

Description Medium-sized rodent. Pelage soft. Dorsal pelage medium to dark brown, tinged with rufous; hairs dark grey at base, with buff, rufous or black tip. Ventral pelage greyish-white (not pure white); hairs dark grey at base, off-white at tip. Head similar in colour to dorsal pelage. Ears darkly pigmented, sparsely covered with short buff or brown hairs. Chin and throat off-white. Upper surface of feet off-white. Tail long (95–115% of HB), ringed with scales, sparsely covered with short bristles, dark above, pale below. Skull: molars moderately broad (M^1 2.0–2.2 mm); incisors orthodont. Nipples: $0 + 2 = 4$.

Geographic Variation In Malawi, tail is slightly shorter than HB (95%); in Zambia, tail is longer than HB (115% of HB) (Davis 1975b).

Similar Species

A. chrysophilus. Dorsal pelage brighter and ventral pelage whiter; tail relatively longer (120% of HB); skull narrower; molars narrower ($M^1 < 2.0$ mm); incisors opisthodont.

A. kaiseri. Dorsal pelage pale brown; tail relatively shorter (70–95% of HB), pale below and with sparse hair; molars broader ($M^1 > 3.2$ mm).

Distribution Endemic to Africa, Zambezian Woodland BZ. Recorded from NE Angola, S DR Congo, N Zambia and Malawi. Limits of distribution uncertain (Musser & Carleton 1993, 2005; Crawford-Cabral 1998), although it is unlikely that the species occurs in southern Africa south of the Zambezi–Cunene rivers. Record from E Zimbabwe probably based on misidentification of a young *A. silindensis* (Chimimba *et al.* 1999).

Habitat Grasslands with bushes and trees, as well as cultivated areas (Hanney 1965). May frequent termite mounds in open woodland (Ansell 1960, De Graaff 1981). Also recorded from edge of montane forest in bracken or grass (Ansell & Ansell 1973) and along a river bank in alpine meadows with shrub patches (2200–2300 m; Chitaukali *et al.* 2001). Although mostly found at higher altitudes, has been reported to occur at 800 m (Mpemba) and 900 m (Likhubula) in S Malawi (Ansell & Dowsett 1988). Type specimen probably from lower slopes of Nyika Plateau in northern Malawi (Ansell & Ansell 1973, Ansell & Dowsett 1988).

Abundance Little information. In Malawi (Nyika Plateau), the original series included 15 *A. nyikae*, but only one *A. chrysophilus*.

Remarks Nocturnal and terrestrial. Perhaps communal or semi-communal (De Graaff 1981). Females with 2, 4 and 5 embryos reported from Zambia (Ansell 1960).

Conservation IUCN Category: Least Concern.

Aethomys silindensis SELINDA VELD RAT (SELINDA AETHOMYS)

Fr. Rat des rochers du Mont Selinda; Ger. Selinda Veld-Ratte

Aethomys silindensis Roberts, 1938. Ann. Transvaal Mus. 19: 245. Chirinda Forest, Mt Selinda, E Zimbabwe.

Taxonomy Ellerman *et al.* (1953) regarded *A. silindensis* as a subspecies of *A. chrysophilus*. Considered a valid species on the basis of large size and five-rooted M^1 (cf. small size and four-rooted M^1 in *A. chrysophilus*) (Meester *et al.* 1964, Davis 1975b), a viewpoint

supported by quantitative and qualitative analysis of morphological characters (Chimimba 1998, Chimimba *et al.* 1999). Differs from *A. chrysophilus* in cuticular scale pattern and groove characters of the hair (Keogh 1985). Synonyms: none. Chromosome number: not known.

Aethomys silindensis

Description Large robust rodent with brown dorsal pelage, yellowish-brown feet, and long scaly tail. The largest species of *Aethomys*. Dorsal pelage buffy-brown to dark brown; hairs brownish-grey at base and black at tip. Some black-tipped hairs also occur on head, neck and rump. Flanks paler. Ventral pelage pale grey or buffy-white. Upper lips, chin and throat buffy-white. Ears brown with thin covering of bright brown hairs. Feet bright yellowish-brown. Tail long (92–114% of HB), brownish above, paler below, with scales arranged in rings. Skull robust; pronounced supraorbital ridges, which extend posteriorly to junction with occipital crest; M^1 moderately broad (2.20–2.30 mm) with five roots; M^3 has large isolated anterior cusp. Nipples: not known.

Geographic Variation None recorded.

Similar Species

A. chrysophilus and *A. ineptus*. Similar in appearance, but smaller; molar teeth narrower ($M^1 < 2.0$ mm with four roots).

Distribution Endemic to Africa. Zambezian Woodland BZ. Known only from three localities in E Zimbabwe. Range may extend northwards along the escarpment in E Zimbabwe and into adjacent, ecologically similar areas of W Vila Pery District of Mozambique (Roberts 1951, Skinner & Smithers 1990).

Habitat Open areas with thick vegetation in valleys at ca. 700 m where rainfall is 1200–1400 mm/year. Not recorded from forest habitats. Also recorded in rocky areas with heavy vegetative cover (Smithers 1983).

Abundance Rare and restricted in distribution.

Remarks Apparently no other information available.

Conservation IUCN Category: Vulnerable.

Aethomys stannarius WEST AFRICAN VELD RAT (WEST AFRICAN AETHOMYS)

Fr. Rat des rochers occidental; Ger. Zinn Veld-Ratte

Aethomys stannarius (Thomas, 1913). Ann. Mag. Nat. Hist., ser. 8, 11: 482. Kabwir, Bauchi Province, Nigeria.

Taxonomy Originally described in the genus *Epimys*. Considered to be a subspecies of *A. hindei* by Davis (1975b) and Happold (1987) but more usually considered to be a valid species (Ellerman 1941, Rosevear 1969, Hutterer & Joger 1982, Denys & Tranier 1992, Musser & Carleton 1993, 2005). See Rosevear (1969) for further details. Synonyms: none. Chromosome number: not known.

Description Medium-sized, relatively long-haired rodent with soft pelage. Description based on a single specimen (Rosevear 1969). Dorsal pelage medium-brown mixed with black and yellowish-brown

hairs. Longer 'sub-bristles' (14–15 mm) and blackish-brown 'guard hairs' (ca. 20 mm) extend beyond the pelage. Flanks greyish to pale brown. Ventral pelage white; hairs pure white or white with greyish-tan base. Colours of ventral pelage and flanks not clearly delineated. Ears with short hairs above and below. Feet densely covered with white hairs on upper surface. Tail long (ca. 110% of HB), scaly, with inconspicuous black hairs. Auditory bullae: 5.4, 6.9 mm, $n = 2$ (cf. *A. hindei*). Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

A. hindei. Mean values of HB and E larger, tail usually relatively shorter (95–110% of HB); auditory bullae longer (7.03 mm); distribution may overlap slightly in Cameroon.

Distribution Endemic to Africa. Guinea Savanna BZ. Recorded from N Nigeria (Happold 1987, as *A. hindei*) to N Cameroon (Mandara Mts; Eisentraut 1975).

Habitat Grassland, woodland savanna, bush, cultivated areas and forest edges where there is moderate to dense cover.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Risk attributed to human-induced habitat loss and/or degradation. Area of geographic distribution very small and disjunct.

Measurements

Aethomys thomasi THOMAS'S VELD RAT (THOMAS'S AETHOMYS)

Fr. Rat des rochers de Thomas; Ger. Thomas Veld-Ratte

Aethomys thomasi (de Winton, 1897). Ann. Mag. Nat. Hist., ser. 6, 20: 327. Galanga, Angola.

Taxonomy Originally described in the genus *Mus*, but subsequently allocated to *Dasymys* by Allen (1939). Later *thomasi* was considered to be a subspecies of *Aethomys kaiseri* (Ellerman *et al.* 1953), but was re-instated as a full species by Crawford-Cabral (1999) and Musser & Carleton (1993, 2005). Difficult to distinguish from *vernayi* (now a subspecies of *A. kaiseri*) (Crawford-Cabral 1999). Synonyms: none. Chromosome number: not known.

Description Medium-sized rodent. Dorsal pelage uniformly grizzled rufous-brown. Ventral pelage greyish-white; hairs greyish-black at base, greyish-white at tip. Ears round, sparsely covered with short reddish-brown hairs. Limbs and feet short and stout; hindfeet with five plantar pads. Tail long (ca. 83% of HB), but relatively shorter than in other species in the genus, uniformly brown, with scales and evenly covered with short stiff hairs. Skull: upper molars moderately broad (M^1 : ≤ 2.2 mm); incisors opisthodont. Nipples: not known.

Geographic Variation None recorded.

Similar Species

A. kaiseri. Mean HB similar; T on average relatively longer; $M^1 > 3.2$ mm; perhaps partially sympatric in Angola.

A. bocagei. Mean HB larger ($\sigma \sigma$) or smaller ($\varphi \varphi$); T on average relatively longer; partially sympatric in Angola.

A. chrysophilus. Mean HB smaller; T on average relatively longer; $M^1 < 2.0$ mm; partially sympatric in Angola.

Distribution Endemic to Africa. Zambezan Woodland BZ. Recorded only from the plateaux of W and C Angola (Crawford-Cabral 1998). Probably parapatric with *A. kaiseri* in the highlands of C Angola (Crawford-Cabral 1999).

Habitat Uncertain. 'A large number of animals were collected on termitaria' (Crawford-Cabral 1999).

Abundance Probably rare (Crawford-Cabral 1999).

Remarks Half-grown specimens recorded in Feb, Mar, Aug and Dec; recently born young in Mar; 'appears that breeding is fairly continuous throughout the year' (Hill & Carter 1941).

Conservation IUCN Category: Least Concern.
Status needs further evaluation.

GENUS *Apodemus*

Field Mice

Apodemus Kaup, 1829. Skizz. Entwickel.-Gesch. Nat. Syst. Europ. Thierwelt 1: 154. Type species: *Mus agrarius* Pallas, 1771.

Apodemus sylvaticus.

The genus comprises 21 species (Musser & Carleton 1993) distributed widely throughout the Palearctic region from Britain to China and Japan, and southwards to the Middle East, Nepal, Burma and N India. Member of the genus live, typically, in woods, hedgerows, field and gardens, and in other moist habitats. One species in the genus is represented in NW Africa (Morocco, Algeria, Tunisia) and is assumed to have reached Africa from Spain. None of the species in the genus that occur in Israel (and other countries of the Middle East) has reached Egypt or NW Africa. Further details are given in the species profile.

Figure 60. Skull and mandible of *Apodemus sylvaticus* (skull: MNHN 1957/538; mandible: BMNH 12.6.12.112). Details of the occlusal surface of the upper molar teeth are obscure and not included.

The characters of the genus are small size (HB: ca. 70–120 mm, WT: ca. 15–25 g), relatively long tail (usually about 100% of HB), soft pelage, brownish dorsal pelage and paler ventral pelage; narrow hindfeet with five digits, Digits 2, 3 and 4 long, Digits 1 and 5 shorter. Skull characters include rather broad braincase, long rostrum, wide anterior palatal foramina, narrow zygomatic arches, and absence of supraorbital ridges (Figure 69). Upper cheekteeth complex; M^1 larger than M^2 , M^2 larger than M^3 ; t_3 of M^1 well developed (Ellerman 1941).

The species in the genus are morphologically rather similar, and traditional morphometrics is often inadequate to distinguish between the species. Modern techniques, such as DNA sequencing of cytochrome *b* and 12S rRNA, provide better means for separating the species. There are numerous studies on the taxonomy and phylogeny of the genus in the Palearctic region (see Musser & Carleton 1993, 2005, for details and references).

The single species of the genus in Africa is *Apodemus sylvaticus*

Christiane Denys

Apodemus sylvaticus LONG-TAILED FIELD MOUSE (WOOD MOUSE)

Fr. Mulot sylvestre; Ger. Waldmaus

Apodemus sylvaticus (Linnaeus, 1758). Syst. Nat., 10th edn., 1: 62. Uppsala, Sweden.

Taxonomy Originally described in the genus *Mus*. Only information relevant to North Africa is given in this profile (see Musser & Carleton 2005 for further details of the species as a whole). The Wood Mouse in N Africa was originally described as *Mus algerus*. This specific name is no longer valid, and most authorities consider that the type specimen (now lost) was perhaps a representative of *sylvaticus*. The origins of *A. sylvaticus* in North Africa are uncertain. Either the species dispersed from Europe at the end of the last glaciation, or it was introduced through human activities. mtDNA studies show that populations of *A. sylvaticus* in N Africa are more closely related to populations in Spain, and much less related to populations from Sicily and the Balkans; human introduction from SW Europe across the Straits of Gibraltar in the early or middle Pleistocene (700,000 mya) is likely. Synonyms in Africa: *algerus*, *hayi*, *ifranensis*, *rufescens*. Subspecies: four were described from North Africa (see Saint Girons & Van Bree 1962 and Saint Girons 1972 for details) but none is now considered valid (Kock & Felten 1980, Kowalski &

Rzebik-Kowalska 1991). Analysis of many gene loci of North African specimens showed high genetic homogeneity between populations (Filippucci 1992), confirming that subspecific recognition is not warranted. Likewise, study of mtDNA restriction pattern fragments from 28 samples (several populations) throughout N Africa show that all are very homogeneous. Chromosome number: $2n = 48$, $FN = 48$ (Matsubara *et al.* 2004; non-African populations).

Description Small brownish mouse with large naked ears and bicoloured tail. Pelage soft and silky. Dorsal pelage rufous-brown or grey; hairs dark grey at base, brown at tips. Pelage darker on back and flanks due to numerous long black guard hairs on back and flanks. Colour of dorsal pelage varies geographically. Ventral pelage greyish-white; hairs dark grey on basal half, white on terminal half. Colours of dorsal and ventral pelage clearly delineated. Head similar in colour to dorsal pelage. Eyes dark, large. Ears large, darkly pigmented, round at tip, with small rufous or chestnut-brown hairs. Fore- and hindfeet white. Forefoot with four digits. Hindfoot with five digits; Digits 1 and 5 shorter than Digits 2, 3 and 4; all digits with claws. Tail long (ca. 107% of HB), with small scales arranged in rings, bicoloured, brown above, white below. Nipples: $1 + 2 = 6$.

Geographic Variation Dorsal pelage varies: grey in summer and winter (Middle Atlas), grey in winter and brown in summer (coastal plains of Morocco); rufous-brown (drier habitats, High Atlas).

Similar Species

Mus spretus. Smaller in all body measurements; tail ca. 80% of HB; often syntopic in North Africa.

Distribution Mediterranean Coastal BZ. Recorded from coastal and mountainous regions of Morocco, Algeria and Tunisia. Primarily a Palearctic species, widespread in Europe and eastwards to China (see genus profile).

Habitat Shrubs on coastal sand dunes, dense forests of Middle and High Atlas Mts, pine forests and high mountain cedar forests (Aulagnier & Thévenot 1986, Kowalski & Rzebik-Kowalska 1991). Preferred habitats are where rocks and low vegetation are present (Khidas *et al.* 2002). May occur in meadows, but absent from open

Apodemus sylvaticus

and semi-arid habitats. Wood Mice avoid habitats altered by human activities, particularly agricultural areas (Khidas *et al.* 2002).

Abundance Common, especially in forested habitats. In N Algeria, Wood Mice comprised 12% of captured small mammals in mixed forest ($n = 43$, 4 spp.), 80% in *Quercus-Ilex-Olea* forests ($n = 10$, 2 spp.) and 100% in high mountain cedar forest ($n = 25$, 1 sp.) (Khidas 1993). Wood Mice tend to be less abundant in habitats where they co-exist with Algerian Mice (*Mus spretus*) (Khidas *et al.* 2002).

Adaptations Nocturnal and terrestrial. Construct burrows, often under rocks.

Foraging and Food Omnivorous, mainly seeds and fruits. The diet of Wood Mice in Algeria (assessed by analysis of stomach contents) includes seeds, acorns, fruits of *Myrtus communis* and *Ficus carica* (K. Khidas pers. comm.). In cultivated areas, leaves, stems and flowers comprise 19.5% of the diet. Arthropods comprise up to 25% of the diet. In Morocco, the diet is seeds, berries, insects, dry fruits and acorns; removal and storage of acorns is considered to assist in the regeneration of oak forests (Aulagnier & Thévenot 1986). On a yearly basis, seeds comprise 60–85% of the diet, and insects and green herbage each comprise 10% or less (Harich & Benazzou 1990).

Social and Reproductive Behaviour No information (for Africa).

Reproduction and Population Structure The timing of reproduction depends on locality. In the mountains of Morocco, reproduction occurs in the spring, summer and autumn, with peaks in spring (Mar–Apr) and autumn (Sep–Oct) (Saint Girons 1972), and ceases during the winter months (Oct–Mar). Similarly, in the mountains of Algeria (where there is snow during winter), reproduction is in spring and summer, as in Europe (Kowalski & Rzebik-Kowalska 1991). In contrast, on the hot coastal plains at lower altitudes, reproduction is limited to the cooler (winter) months of the year: in Morocco (near Rabat) from Sep to Apr, with peaks in

Nov–Dec and Feb (Harich & Benazzou 1990), and in Algeria (near Oran) pregnant ♀♀ were found only Oct–Mar (Kowalski 1985). Embryo number: 4.2 (3–6, mode 4, $n = 15$; Morocco; Harich & Benazzou 1990); 4.3 (3–5, Algeria; Kowalski 1985). Because of seasonality of reproduction, population numbers (at lower altitudes) increase from Dec to Apr, and decrease from Apr to Sep; individuals more than one year in age die during the summer months.

Predators, Parasites and Diseases Remains found occasionally in pellets of *Tyto alba* (Kowalski & Rzebik-Kowalska 1991) in Algeria. May also be preyed upon by jackals (Khidas 1988) and the owl *Athene noctua* (B. Baziz pers. comm.). Fleas found on Wood Mice in Algeria include *Typhloceras p. poppei*, *Rhadinopsylla masulana* and *Leptopsylla taschenbergi* (Beaucornu & Kowalski 1985).

Conservation IUCN Category: Least Concern.

Widespread and common, although geographic range in Africa is limited and category of threat unknown.

GENUS *Arvicanthis*

Grass Rats

Arvicanthis Lesson, 1842. Nouv. Tabl. Regn. Anim. Mammalifères, p. 147. Type species: *Lemmus niloticus* É. Geoffroy Saint-Hilaire, 1803.

The genus currently includes seven species, and is one of the most widespread and abundant of genera of African rodents (Table 30). Species of the genus are recorded from grassland to wooded savannas and moorlands of sub-Saharan Africa, in mesic habitats in semi-desert regions, and even from some massifs and wadis of the Sahara. The distribution extends from Senegal to Egypt, and southwards through eastern Africa to Zambia. In Ethiopia, the four species show altitudinal zonation: *A. niloticus* sea level to 2000 m, *A. neumanni* 400–1500 m, *A. abyssinicus* 2000–3400 m and *A. blicki* 2750–4100 m. Extralimital populations (of *A. niloticus*) can be found in coastal Yemen and Oman.

Arvicanthis are medium-sized murine rodents characterized by a distinctive harsh grizzled pelage. The genus is closely related to the genera *Desmomys*, *Lemniscomys*, *Mylomys*, *Pelomys* and *Rhabdomys*, but

recognizable by its mammary formula ($1 + 2 = 6$), short muzzle and a tail usually shorter than head and body. It can be distinguished from *Desmomys*, *Mylomys* and *Pelomys* by ungrooved upper incisors, and from *Lemniscomys* and *Rhabdomys* (both of which have very obvious stripes contrasting with the surrounding pelage) by the presence of a single, usually faint to nearly invisible, black mid-dorsal stripe. Unlike *Desmomys*, *Lemniscomys*, *Mylomys* and some *Pelomys*, Digit 5 on the forefoot is greatly reduced but still bears a claw. Skull characters include a widening of the median part of zygomatic arch, a wide zygomatic plate, a narrow interorbital constriction and strong supraorbital ridges (Figure 61). The presence of five roots at M¹, a particularly large M³ and pronounced dental lamination scheme also distinguish the genus from the previously mentioned ones.

Table 30. Species in the genus *Arvicanthis*. Arranged in order of increasing mean head and body length.
(n. d. = no data.)

| Species | HB mean (mm) | T mean (mm) [% of HB] | Dorsal pelage | GLS mean (mm) | Chromosome number | Notes |
|-----------------------|----------------------|---------------------------|---|------------------------|----------------------|---|
| <i>A. neumanni</i> | 97.8 | 93.0 [95%] | Brownish-orange; speckled cream | 27.6 | 2n = 62, FN = 66–67 | Ethiopia, Somalia, Kenya (dry, low altitudes) |
| <i>A. nairobae</i> | 139 | 101 [73%] | Chestnut-brown | 35.7 (♂ ♂), 32.4 (♀ ♀) | 2n = 62, aFN = 78 | Kenya and Tanzania, probably only east of Rift Valley (also ? S Ethiopia) |
| <i>A. abyssinicus</i> | 140.5 | 110.4 [80%] | Dark brown, boldly flecked | 32.0 | 2n = 62, FN = 68 | Ethiopia, mostly west of Rift Valley (2000–3400 m) |
| <i>A. rufinus</i> | 143.8 | 138.2 [96%] | Buffy-brown, flecked black | 33.6 | 2n = 62, aFN = 76 | Western West Africa, eastwards to Nigeria |
| <i>A. niloticus</i> | 150.8 | 129.7 [ca. 85%] | Buffy-brown, heavily speckled black and yellow | 32.9 | 2n = 62, aFN = 62–64 | Widespread. Nile Valley, Ethiopia (<i>dembeensis</i>), East Africa |
| <i>A. ansorgei</i> | 151 | 134 [90%] | Buffy-brown, heavily speckled | 33.4 | 2n = 62, aFN = 74–76 | Guinea-Bissau, Senegal, Mali, Burkina |
| <i>A. blicki</i> | 161 (♂ ♂), 158 (♀ ♀) | 100 (♂ ♂), 99 (♀ ♀) [62%] | Silvery-brown to greyish-brown, speckled silver/white | n. d. | 2n = 48, aFN = 64 | Ethiopia, east of Rift Valley (2750–4000 m) |

Arvicanthis rats are terrestrial, and often nest in very shallow burrows or directly under grasses on the ground surface. A significant part of their activity may be diurnal, and they often do well in the

immediate vicinity of humans (gardens, enclosures and irrigated farmlands), although rarely in houses. They are predominantly herbivorous. Population numbers may become very large when environmental conditions are favourable, and they may be potentially harmful to agriculture (especially *A. niloticus* in the Sahel Savanna BZ). They are also known as hosts of various viral, bacterial or protozoan diseases transmissible to humans.

Species within the genus were traditionally distinguished by pelage colour and body measurements, but identification is complicated by considerable inter-individual variability. Recent investigations using cytogenetic and molecular data have revealed the presence of at least three sibling species (*A. ansorgei*, *A. niloticus* and *A. rufinus*) in western and central Africa, where the single species *A. niloticus* was previously recognized. These studies have also shown that the diversity within the genus is organized in two well-differentiated clades that may have split around 4 mya: one clade contains *A. abyssinicus*, *A. blicki*, *A. neumanni* and *A. niloticus*, and the other *A. ansorgei*, *A. nairobae* and *A. rufinus*. Morphological, cytogenetic and molecular analyses have confirmed that the Ethiopian species *A. dembeensis* is synonymous with *A. niloticus*. The definition and distribution limits of several species (*A. ansorgei*, *A. nairobae*, *A. neumanni*, *A. rufinus*) require further investigation, and additional species may prove to be present, especially in central and eastern Africa.

The species are distinguished on karyology, size, pelage colouration (and amount of ‘speckling’) as well as on cytological and molecular characters.

Figure 61. Skull and mandible of *Arvicanthis niloticus* (HC 62).

Laurent Granjon & Jean-François Ducroz

Arvicanthis abyssinicus ETHIOPIAN GRASS RAT (ABYSSINIAN GRASS RAT)

Fr. Rat roussard d'Abyssinie; Ger. Äthiopische Grasratte

Arvicanthis abyssinicus (Rüppell, 1842). Mus. Senckenberg. 3: 104. Entschetgab, Simien Mts, Ethiopia.

Taxonomy Originally described as *Mus abyssinicus*. Many geographic varieties of this species have been described in Ethiopia based upon variation in pelage colour and size (Afework Bekele *et al.* 1993). However, Rupp (1980), Demeter (1982) and Yalden *et al.* (1976) consider that *Arvicanthis* consists of series of sibling species/subspecies – *A. abyssinicus*, *A. blicki*, *A. somalicus* and *A. niloticus dembeensis*, which live in different habitats and at different altitudes. Each of these forms is considered to be a separate taxon here. Synonyms: *fluvicinctus*, *rufodorsalis*, *saturatus*. Subspecies: none. Chromosome number: $2n = 62$, $FN = 68$ (Capula *et al.* 1997).

Description Medium-sized dark rodent, intermediate in size between *A. somalicus* and *A. blicki*. Pelage slightly rough and coarse. Dorsal pelage brownish-black, boldly streaked with ochre or cream, especially on flanks; dorsal hairs 8–10 mm, black at base, ochre or cream or black at tip; black basal colouration clearly visible on surface of pelage. Pure black mid-dorsal stripe from neck to base of tail in some individuals. Ventral pelage greyish-ochre; hairs 3–4 mm, greyish-black at base, cream or white on terminal half. Head similar in colour to dorsal pelage. Ears rounded, pigmented brown or rufous, sparsely covered with short rufous hairs. Fore- and hindlimbs ochre-rufous above, almost naked below; claws pale. Tail long (ca. 80% of HB), bicoloured with small bristles, dark above, pale below; clearly ringed with small scales. Some 'albino' individuals with very pale creamy-cinnamon pelage recorded in Horogudru District, Wollega Province, Ethiopia (BMNH). Skull: ungrooved upper incisor teeth. Nipples: not known.

Geographic Variation None recorded.

Similar Species

A. blicki. On average larger; east of the Rift Valley in Ethiopia, mostly at higher altitudes (2750–4100 m); chromosome number: $2n = 48$, $FN = 64$.

A. neumanni. On average much smaller; lowlands of Ethiopia at lower altitude (400–1500 m); chromosome number: $2n = 62$, $FN = 66$ –67.

A. niloticus. On average slightly larger with longer tail (mean 139 mm); lowlands of Ethiopia at lower altitudes (0–2000 m), widespread in sub-Saharan Africa and East Africa; chromosome number: $2n = 62$; $aFN = 62$ –64.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Widely distributed in the grasslands of the Ethiopian plateaux, mainly west of the Rift Valley and marginally to the east of the Rift Valley. Altitudinal range: 2000–3400 m (Rupp 1980).

Habitat Open grasslands usually at altitudes above 2000 m. In the Simien Mts, short grass steppe, rocky areas in short grass steppe, and *Carex* moorland along creeks are preferred habitats (Güttinger *et al.* 1998). Avoids heavily grazed areas as well as long grass–short grass mosaics. May occur in cereal fields at higher altitudes (Güttinger *et al.* 1998).

Abundance Abyssinian Grass Rats comprised 77% of the small rodents ($n = 57$) in the grasslands of the Simien Mountains (Müller 1977). Population numbers are highest in the late dry season (Jan–Mar) after many young have entered the population, and lowest in the wet season (May–Oct). Density varied from 65–75/ha (wet season) to 130–250/ha (dry season), and biomass varied from 4900–6800 g/ha (wet season) to 14,000–16,500 g/ha (dry season) (Müller 1977). Another study also found this species to be the commonest species in the Simien Mts (59 of 173; 6 spp. rodents, 1 sp. shrew) (Güttinger *et al.* 1998).

Adaptations Diurnal and terrestrial. The pelage is rather thin and animals may suffer from moist cold; hence activity is during the day and reproduction is limited to the dry season (when conditions are most favourable).

Foraging and Food No detailed information but presumed to be herbivorous.

Social and Reproductive Behaviour These grass rats have been observed entering their nests in groups, suggesting that they are gregarious. Home-range varied according to sex and season of the year: ♂♂ – 2750 m² (wet season), 1400 m² (dry season); ♀♀ – 950 m² (wet season), 600 m² (dry season) (Müller 1977). Grass rats live syntopically with *Stenocephalemys griseicauda*.

Reproduction and Population Structure In the Simien Mountains N. P., Ethiopia, reproduction occurs mainly in the first

*Arvicanthis abyssinicus*

half of the dry season (Oct–Dec) and ceases during the wet season (Mar–Sep) (Müller 1977). Young animals enter the population mostly in Nov–Jan. Litter-size: 5.6 (3–9, $n = 18$). Weight at birth: ca. 4 g (data from captive animals; Afework Bekele unpubl.).

Predators, Parasites and Diseases Birds of prey are frequently observed perching and catching individuals.

Conservation IUCN Category: Least Concern.

Deforestation of the highlands has expanded the range of the species by creating more open grounds. The species has become a pest of crops in fields and storage places.

Arvicanthis ansorgei ANSORGE'S GRASS RAT (SUDANIAN ARVICANTHIS)

Fr. Rat roussard soudanien; Ger. Ansorges Grasratte

Arvicanthis ansorgei Thomas, 1910. Ann. Mag. Nat. Hist., ser. 8, 5: 353. Gunnal, Guinea-Bissau.

Taxonomy Long considered as belonging to *A. niloticus* (Rosevear, 1969). Characteristics of the chromosomes distinguish this species from its sibling species *A. niloticus* and *A. rufinus* (Ducroz 1998; Fadda 1998; Volobouev *et al.* 2002). Synonyms: none. Chromosome number: $2n = 62$; aFN = 74–76.

Description Medium-sized, robustly built rat. Dorsal pelage usually buffy-brown heavily flecked with black and yellow; hairs dark brown at base with buff-yellowish subterminal zone and blackish tip. Rump and base of tail often suffused with pale red, especially in older individuals. Ventral pelage whitish to grey. Head blunt, short muzzle. Ears rounded and reddish. Digit 5 on forefeet considerably reduced but still functional; Digit 1 vestigial. Soles of hindfeet generally dark. Tail long (ca. 90% and usually shorter than HB), dark above, whitish or pale brown below. Skull: ungrooved upper incisor teeth. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

A. niloticus. Chromosome number: $2n = 62$, aFN = 62–64; more northern distribution.

A. rufinus. Chromosome number: $2n = 62$, aFN = 70; more south-eastern distribution (Ducroz 1998, Fadda 1998, Volobouev *et al.* 2002).

Distribution Endemic to Africa. Sudan Savanna BZ of West Africa. Recorded from Guinea-Bissau (type locality) and Casamance (SW Senegal) across Mali to S Burkina (Ducroz 1998, Dobigny *et al.* 2002b). Southern and eastern limits of distribution insufficiently known. Sympatry with *A. niloticus* recorded in a vast area of central Mali (Sicard *et al.* 2004).

Habitat Sudan savannas and grasslands (annual rainfall 1000–2500 mm), except in the inner delta of the Niger R. in Mali where it occurs in more arid climatic conditions (Sicard *et al.* 2004). Also found in bushland, croplands, farms and villages, but rarely inside houses.

Abundance May be locally very abundant, as along the Niger R. south of Bamako (Sicard *et al.* 2004).

Adaptations Mainly diurnal, with activity peaks at dawn and dusk, reportedly less diurnal than *A. niloticus* (B. Sicard unpubl.).

Arvicanthis ansorgei

Builds nests of fine grass on the surface or in shallow burrows. Intensively uses runways radiating out from the nest through matted grass. More difficult to catch using live-traps than *A. niloticus* (L. Granjon & J.-F. Ducroz unpubl.).

Foraging and Food Probably mainly herbivorous.

Social and Reproductive Behaviour Gregarious species, sometimes found in colonies of several adult ♂♂ and ♀♀, with young (B. Sicard, unpubl.). Displays less aggressiveness than *A. niloticus* when handled, but apparently quite aggressive towards conspecifics in captivity (J.-M. Duplantier & L. Granjon unpubl.).

Reproduction and Population Structure Litter-size: 5.40 ± 0.28 ($n = 9$ pairs; S Senegal and Mali; Ducroz *et al.* 1997). Reproductive biology insufficiently known, but probably less prolific than *A. niloticus*.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Arvicanthis blicki BLICK'S GRASS RAT

Fr. Rat roussard d'Ethiopie; Ger. Blicks Grasratte

Arvicanthis blicki Frick, 1914. Ann. Carnegie Mus. 9: 20. Hora Mt base camp, Southern Chilalo Mts, Ethiopia. 2750 m.

Taxonomy Originally described as a subspecies of *A. abyssinicus*, but now considered to be a valid species. In morphology, ecology, geographic distribution and habits, *A. blicki* is a very distinctive species (Musser & Carleton 2005). More closely related to *A. abyssinicus* than to any other species of *Arvicanthis*. Synonyms: none. Chromosome number: $2n = 48$, $aFN = 64$ (Corti *et al.* 1996).

Description Large rodent, silvery-brown with faint dark mid-dorsal stripe; the largest species of *Arvicanthis* in Ethiopia. Dorsal pelage greyish-brown, strongly flecked with creamy-white or silvery-white; hairs 7–10 mm, greyish-black at base, with terminal band of pale ochre, creamy-white or silvery-white, and usually with dark russet or black tip. Thin black mid-dorsal stripe from neck to base of tail; sometimes obscure or absent. Flanks paler than dorsal pelage, due to absence of dark-tipped hairs. Ventral pelage paler than dorsal pelage; hairs rather sparse, ca. 5 mm; hairs pale brown at base, cream, buff or white at tip. Head similar to dorsal pelage; black vibrissae. Ears small, rounded, darkly pigmented, and well covered with short buff or cream hairs. Subauricular and postauricular white or cream spot (not rufous as in many *Arvicanthis* spp.). Limbs similar in colour to body. Forelimb with four digits, Digit 1 absent, Digit 5 reduced. Hindfoot with five digits, Digits 1 and 5 reduced. All digits with dense hairs above and dark claws. Tail short (ca. 62% of HB), dark above with dark bristles, paler below. Skull: ungrooved upper incisor teeth. Nipples: not known.

Geographic Variation None recorded.

Similar Species

A. abyssinicus. On average smaller (mean HB: 140 mm); mostly west of Rift Valley in Ethiopia at lower altitude (2000–3400 m); chromosome number $2n = 62$, $aFN = 68$.

A. neumanni. Much smaller (mean HB: 97 mm); lowlands at lower altitude (400–1500 m); chromosome number: $2n = 62$, $FN = 66$ –67.

A. niloticus. On average smaller (mean HB: 153 mm); lowlands at lower altitude (0–2000 m).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Confined to plateaux of Ethiopia, east of Rift Valley, at high altitudes from 2750 to 4100 m (Yalden *et al.* 1976, Yalden & Lagen 1992). Probably occurs only in Chilalo and Bale Mts of Ethiopia.

Habitat Grasslands at medium and high altitudes. Also found in afroalpine habitats (3400–4200 m) characterized by short, sparse vegetation, heavy frosts and low rainfall (Sillero-Zubiri 1994).

Abundance Population numbers fluctuate seasonally, increase during the dry season (Nov–Jan) and fluctuate during the mid-wet season (Jun–Jul). Sillero-Zubiri *et al.* (1995a) recorded densities of 21/ha on the Sanetti Plateau in Bale Mountains N. P. (4050 m), and 53/ha in the Web Valley (3450 m).

Adaptations Diurnal and terrestrial. Trapping results showed that 80% of individuals (n = 584) were captured during the morning (assessed as 07:00–12:30h) and 20% during the afternoon (assessed as 12:30–18:30h). Observations showed few animals (this species and *Lophuromys melanonyx*) were above ground before about 09:00h or after about 15:30h (Sillero-Zubiri *et al.* 1995a). Lives in colonies in burrows, often in abandoned *Tachyoryctes macrocephalus* burrows.

Foraging and Food Herbivorous. The few records from afroalpine moorland (3900 m) show that the diet is mostly dicotyledonous leaves, as well as some monocotyledonous leaves (Yalden & Lagen 1992).

Social and Reproductive Behaviour Colonial, living in mixed colonies with *Lophuromys melanonyx*. When alarmed, emits a high-pitched whistle to provide warning of any potential danger (Yalden & Lagen 1992).

Reproduction and Population Structure Reproduction occurs throughout the year; with the greatest number of animals reproducing in the wet season (Apr–Oct) and the least number in the dry season (Nov–Mar). Pregnancies reach peaks (75%) in May and Sep, suggesting at least two litters/♀/year. Embryo number: 3.24 (range of means 2.31–4.17, n = 25; Sillero-Zubiri 1994). The proportion of juveniles in the population is highest (ca. 60%) at the beginning of the dry season (Nov/Dec), but declines throughout the

rest of the dry season and into wet season, to a minimum of 0% in Sep (Sillero-Zubiri *et al.* 1995a). Interestingly, the number of trappable juveniles does not increase markedly in Jul and Aug after the peak of pregnant ♀♀ in Jun, whereas it does increase markedly in Nov and Dec after the peak in Sep (Sillero-Zubiri *et al.* 1995a), suggesting better survival of juveniles in the dry season than in the wet season.

Predators, Parasites and Diseases Blick's Grass Rats are important prey for the Ethiopian Wolf *Canis simensis*; their remains occurred in 54% of predator scats and formed 27% of prey volume (n = 689 predator scats), and were the second most important prey species after the mole-rat *Tachyoryctes macrocephalus* (69% of predator scats). In 'cafeteria' tests, this species is much preferred as a source of food than are Black-clawed Brush-furred Rats *Lophuromys melanonyx* (40% occurrence) (Sillero-Zubiri & Gottelli, 1995).

Conservation IUCN Category: Near Threatened.

Since this species is an important source of food for the endangered Ethiopian Wolf, the survival of the wolf is partly dependent upon the presence of the species.

Arvicanthis nairobae NAIROBI GRASS RAT

Fr. Rat roussard du Kenya; Ger. Nairobi-Grasratte

Arvicanthis nairobae J. A. Allen, 1909. Bull. Amer. Mus. Nat. Hist. 26: 168. Nairobi, Kenya.

Taxonomy The name *nairobae* is the oldest name applicable to samples from east of the Rift Valley in Kenya and Tanzania. Closely related to *A. niloticus* from west of the Rift Valley, and to *A. neumanni*. Two species, *A. nairobae* and *A. neumanni*, are broadly sympatric, and their morphological and geographical relationships require investigation (Musser & Carleton 1993). Ducroz *et al.* (1998), however, have shown, by cytochrome *b* sequencing, that *A. nairobae*

is more closely related to a group of West and central African species (*A. ansorgei*, *A. rufinus*) than to East African species, a result confirmed by Castiglia *et al.* (2003) on karyological grounds. See Musser & Carleton (2005) for further comments. Synonyms: *chanleri*, *pallascens*, *praeceps*, *virescens*. Subspecies: none. Chromosome number: 2n = 62, aFN = 78.

Description Medium-sized grass rat. Dorsal pelage grizzled chestnut-brown. Ventral pelage tan and softer in texture than dorsal pelage. Ears small, held close to head and covered with short brown hairs. Tail short (ca. 73% of HB). Skull: ungrooved upper incisor teeth. Males on average larger than ♀♀.

Geographic Variation None recorded.

Distribution Endemic to Africa. Southern part of Somalia–Masai Bushland BZ, mostly in the highland areas of East Africa. The distribution is uncertain because of the similarity of the species with the Nile Grass Rat *A. niloticus*. Distribution is probably east of the Rift Valley from C Kenya to E and C Tanzania. May extend northwards into S Ethiopia.

Habitat Grasslands and savannas. Colonies of *A. nairobae* are usually found where there is thick woody cover with an understorey of grass, and occasionally in open grassland. Colonies can often be found under dead fallen trees, and especially in the walls of man-made bomas (livestock enclosures made from branches of *Acacia* trees and shrubs piled into fences). In both of these habitats, the exclusion of grazing by ungulates results in thick, tall grass, which supplies both food and cover.

Abundance May be extremely abundant in the walls of bomas, where they are the most numerous species of rodent, comprising 60–90% of rodents. Densities in walls of bomas may reach 100–200 rats/ha.

Adaptations Exclusively diurnal. Even during the hottest times of the year, individuals are fully active during the heat of the day. They do not climb well, but are extremely fast runners. Well-worn trails radiate out and branch for 10–15 m from the centre of the colony. Nairobi Grass Rats can be observed running within the walls of the boma and foraging for seed heads of grasses and leaves close to their trails.

Foraging and Food Little information, but probably similar to Nile Grass Rats (some publications on ‘Nile Rats’ may refer to this species). Probably granivorous and omnivorous, feeding primarily on seed heads and grass leaves. The diet of *Arvicanthis* sp. (possibly *A. nairobae*) in Meru N. P. (Kenya) was mostly grass, with smaller quantities of other plants and arthropods (Neal 1981).

Social and Reproductive Behaviour Very social, living in large colonies.

Reproduction and Population Structure Reproduction is seasonal. Pregnant ♀♀ are captured most often in the wet season (May–Jul) but litters are found occasionally at other times of year. A similar pattern of reproduction recorded for *Arvicanthis* sp. (possibly *A. nairobae*) in Meru N. P. (Neal 1981), where embryo number was 5.5 (2–12). Larger ♀♀ may have up to 27 placental scars (S. Takata unpubl.).

Arvicanthis nairobae

Predators, Parasites and Diseases Predators include snakes, mongooses and genets (which must capture them at dusk). One adult individual (possibly the mother) was seen chasing a snake (*Psammophis* sp.) that was carrying a young rat (approximately 10 days old) into a tree. Fleas (*Xenopsylla* sp.), mites and lice are recorded from wild Nairobi Grass Rats, although ectoparasite loads are generally lower than on other similar-sized species in the same area (S. Takata unpubl.).

Conservation IUCN Category: Least Concern.

Arvicanthis neumanni NEUMANN'S GRASS RAT (SOMALI GRASS RAT)

Fr. Rat roussard de Neumann; Ger. Neumann-Rennmaus

Arvicanthis neumanni (Matschie, 1894). Sber. Ges. Naturf. Freunde Berlin 1894: 204. Barungi, Kondoa District, Central Tanzania.[*Arvicanthis somalicus* Thomas, 1903. Proc. Zool. Soc. Lond. 1902 (2): 312 [1903]. Shuk (= Sheik), Somalia.]

Taxonomy Formerly included in *A. niloticus* but now considered to be one of the four species of *Arvicanthis* in Ethiopia (Yalden *et al.* 1976, Rupp 1980, Demeter 1982, Demeter & Topal 1982, Corbet & Hill 1991). Musser & Carleton (1993) referred to this species as *A. somalicus* (with *neumanni* as a synonym), but in 2005 these authors referred to *A. neumanni* (with *somalicus* as a subspecies). Studies in Ethiopia (as cited here) refer to this species as *A. somalicus*. Whether there are one or two species within '*A. neumanni*' requires further investigation (see Fadda *et al.* 2001, Musser & Carleton 2005). The relationship of this species with *A. nairobiae* is unclear and requires investigation. Synonyms: *reptans*, *somalicus*. Subspecies: none. Chromosome number: $2n = 62$, $FN = 66-67$ (as *A. somalicus*; Awash N. P., Ethiopia; Baskevich & Lavrenchenko 2000).

Description Smallest and palest of the *Arvicanthis* spp. in East Africa. Dorsal pelage brownish-orange, speckled with cream, ochre or grey; hairs grey or black on basal half, ochre or rufous or grey on terminal half. Ventral pelage paler than dorsal pelage; hairs grey on basal half, white or cream on terminal half. Head similar in colour to dorsal pelage; black vibrissae. Ears small, rounded, with short ochre or rufous hairs. Fore- and hindfeet rufous or ochre above. Digits with pale claws. Tail long (ca. 95% of HB). Skull: ungrooved upper incisor teeth. Nipples: not known.

Geographic Variation None recorded.

Similar Species

- A. abyssinicus*. Larger (mean HB: 140 mm); Ethiopia west of Rift Valley at higher altitude (2000–3400 m); chromosome number $2n = 62$, $aFN = 68$.
A. blicki. Much larger (mean HB: 161 mm); Ethiopia east of the Rift Valley at higher altitudes (2750–4100 m); chromosome number: $2n = 48$, $FN = 64$.
A. niloticus. Larger (mean HB: 153 mm); chromosome number: $2n = 62$; $aFN = 62-64$.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Occurs in dry low-altitude habitats in Ethiopia, Somalia and Kenya. In Ethiopia, occurs sympatrically with *A. niloticus* (as *A. dembeensis*) in the Awash N. P. and the lower Omo Valley of Ethiopia (Hubert 1978b).

Habitat Dry bushy and savanna regions from 400 to 1500 m. Frequents arid regions where the ground vegetation is scarce. At Metahara, occurs in sparse *Acacia* scrub where there is little herbaceous vegetation (Demeter 1982).

Abundance Very little information available. However, remains of this species are much more numerous (18:1) than those of

*Arvicanthis neumanni*

A. niloticus (as *A. dembeensis*) in owl pellets from Awash N. P., Ethiopia (Demeter 1982). At this locality, as evidenced by remains in owl pellets, it is one of the commonest small mammals in this region (18%)—cf. *Tatera robusta* (27%), *Crocidura fuscomurina* (14%), *Gerbillus pusillus* (10%), *Acomys cahirinus* (4%).

Remarks Semi-diurnal and terrestrial. Excavates burrows. Makes intricate runways under cover of *Acacia* trees, which are also used by *Acomys cahirinus*. In burnt areas, where there is absence of ground cover, these grass rats may be observed moving around in search of shelter and food. Details of diet unknown, but may feed on *Solanum* berries at some times of the year. Probably gregarious and colonial. An important prey of Spotted Eagle-owls *Bubo africanus* in Awash N. P. (Demeter 1982; see also above).

Conservation IUCN Category: Least Concern.

Arvicanthis niloticus NILE GRASS RAT (UNSTRIPED GRASS RAT)

Fr. Rat roussard du Nil (Rat du Nil); Ger. Nil-Grasratte

Arvicanthis niloticus (E. Geoffroy, 1803). Cat. Mamm. Mus. Nat. Hist. Nat., Paris, p. 186. Egypt.

Taxonomy Originally described in the genus *Arvicola*. Specimens from west of the Nile R. are genetically and morphometrically distinct, and could warrant subspecific status (*testicularis*) (Ducroz 1998, Fadda & Corti 1998). Populations in Ethiopia are sometimes referred to a separate species, *A. dembeensis* (e.g. Yalden *et al.* 1976, 1996), but *dembeensis* is here considered to be a synonym of *A. niloticus* (see Musser & Carleton 2005 for a full discussion on the taxonomy of this species). Synonyms: *centralis*, *centrosus*, *dembeensis*, *discolor*, *jebelae*, *kordofanensis*, *lacernatus*, *luctuosus*, *nubilans*, *major*, *mearnsi*, *minor*, *muansae*, *naso*, *ochropus*, *pelliceus*, *raffertyi*, *reichardi*, *rhodesiae*, *rossii*, *rubescens*, *solatus*, *tenebrosus*, *testicularis*, *variegatus*, *zaphiri*. Subspecies: none. Chromosome number: $2n = 62$, $aFN = 62-64$.

Description Medium-sized, robustly built rat. Dorsal pelage usually buffy-brown heavily flecked with black and yellow; specimens from sub-desert environments distinctly paler (Rosevear 1969); black mid-dorsal stripe absent or clearly visible; hairs dark brown at base with yellowish-buff subterminal zone and blackish tip. Rump often tinged with red or rufous, especially in older individuals. Ventral pelage whitish to grey. Head blunt, muzzle short. Ears rounded and

reddish. Digit 5 on forefoot considerably reduced but still functional; Digit 1 vestigial. Sole of hindfoot generally dark. Tail usually shorter than head and body (ca. 85%), dark above and whitish or pale brown below. Skull: ungrooved upper incisor teeth. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

A. ansorgei (chromosome number: $2n = 62$, $aFN = 74-76$) and *A. rufinus* (chromosome number: $2n = 62$, $aFN = 70$) have more southern distributions (Ducroz 1998; Fadda 1998, Volobouev *et al.* 2002); West Africa only.

A. neumanni: (chromosome number: $2n = 62$, $FN = 66-67$) is much smaller, and restricted to the lowlands of Ethiopia. The other species in Ethiopia (*A. abyssinicus*, *A. blicki*) are confined to higher altitudes.

Distribution Endemic to Africa (but see also below). Sahel and Sudan Savanna BZs, Afroalpine–Afromontane BZ (partly) in Ethiopia, and southwards into parts of Eastern Rainforest–Savanna Mosaic and northern Zambezian Woodland BZ. Widespread in the Nile Valley (but not in the surrounding Sahara Arid BZ) from the Nile Delta in Egypt to the Great Lakes region (west of the Gregorian Rift Valley) in East Africa. In Ethiopia (as *dembeensis*), occurs in lowlands from sea level to ca. 2000 m. Also recorded from Saharan massifs (Adrar des Iforas, Aïr). Although mapped, presence in Benin, Zambia and W Tanzania uncertain. Sympatric with *A. ansorgei* in a vast area of central Mali (Sicard *et al.* 2004). An isolated population in SW Arabia.

Habitat Savannas and grasslands, often not far from water; recorded from arid steppes to moister grasslands where annual rainfall is 200–1200 mm. May occur in bushes and thickets. Common in croplands, farms and villages, but seldom found inside houses.

Abundance May be a dominant species in grasslands with good cover. Outbreaks can follow abnormally high rainfalls (e.g. density of 100/ha in Sahel Savanna BZ of Senegal in 1976 (Poulet & Poupon 1978). Densities of 600–800/ha have been recorded temporarily in rice fields of N Senegal (Poulet 1982), with a sharp decline in numbers in the dry season. Fluctuations in numbers tend to be greater (from 0 to 80/ha) in grassland habitats than in nearby maize fields (5–18/ha) in the Rift Valley of Ethiopia (Afework Bekele & Leirs 1997). When numerous, may be a pest in agricultural crops.

Arvicanthis niloticus

Adaptations Mainly diurnal (Duplantier & Granjon 1990). Builds nests of fine grass on the surface or in shallow burrows, and may use withdrawal cracks in drained clay soils (Poulet 1982). Intensively uses runways radiating out from the nest through matted grass. Can become arboreal (e.g. when feeding on the fruits of *Balanites aegyptiaca*) in the dry season when other resources are scarce (Poulet 1982).

Foraging and Food Primarily herbivorous; feeds on leaves, shoots and seeds of grasses, and cultivated crops. Small insects may comprise 20% of the diet in the wet season (Rabiu & Rose 1997).

Social and Reproductive Behaviour Gregarious, sometimes found in colonies of several adult ♂♂ and ♀♀ with young. Short-term movements from a few metres in dry rice fields to 20–40 m in sugarcane fields in N Senegal (Poulet 1982). Aggressive towards unfamiliar individuals of the same sex.

Reproduction and Population Structure The length and timing of the reproductive season varies by locality (Fisher 1991). Reproduction generally occurs at the end of, or after, the wet season. The length of the reproductive season is correlated with resource availability so that reproduction throughout the year is possible in favourable conditions. The proportion of reproductively active ♀♀ also varies by locality, e.g. in grasslands of Ethiopia at 1700 m (Afework Bekele & Leirs 1997), pregnant ♀♀ are present in all months of the year, but with a greater proportion of pregnant ♀♀ in the wet season than in the dry season. The range of variability in the number of months when reproduction occurs/year (and proportion of ♀♀ breeding on an annual basis) varies from 12 months/year (32%) at Mweya, Uganda, to ten months (43%) at Crater Track, Uganda (Neal 1981), nine months (52%) at Kitale, Kenya (Taylor & Green 1976), eight months (80%) at Rojwero, Kenya (Neal 1981), seven months (48%) at Kano, Nigeria (Rabiu & Fisher (1989) and five months (n. d.) in Senegal (Poulet & Poupon 1978). Although many variables affect when ♀♀ breed, there is a positive correlation between the number of months when ♀♀ breed and the number of 'humid' months (which in turn affects other environmental characters). A slightly different situation occurs at Khartoum, Sudan (where the number of humid months/year is very low) – pregnant ♀♀ and young occur in the irrigated fields close to Nile R. in most months of the year (Happold 1966a, Ghobrial & Hodeib 1982). Gestation: 21–23 days (Ghobrial & Hodeib 1982). Litter-size: 4.3

(2–10, n = 26; Ethiopia; Afework Bekele unpubl.) to 6.02 ± 7 (n = 56; Senegal; Ducroz *et al.* 1997). Mean litter-size also varies by habitat, e.g. 5.74 ± 2.65 in grasslands and 7.42 ± 2.63 in maize fields (Ethiopia; Afework Bekele & Leirs 1997). Sexual maturity: 2 months (Poulet 1982). Longevity in the wild is less than one year (Poulet 1982).

Predators, Parasites and Diseases Nocturnal and diurnal predators include mongooses, Barn Owls *Tyto alba*, Black-shouldered Kites *Elanus caeruleus*, Crested Hawk-eagles *Lophaelix occipitalis*, Lizard Buzzards *Kaupifalco monogrammicus* and snakes (*Naja* and *Pseustes* spp.) (Kingdon 1974, Bâ *et al.* 2000). Reported to be the reservoir of a fairly large number of diseases, including Rift Valley fever, leishmaniasis, borreliosis, intestinal schistosomiasis and bubonic plague (Gratz 1997). Many species of fleas found on animals, and in nests and burrows, in Egypt, including *Xenopsylla cheopis*, *Echidnophaga gallinacea*, *Synosternus cleopatrae*, *S. pallidus* and *Nosopsyllus londinensis* (Hoogstraal & Traub 1965b).

Conservation IUCN Category: Least Concern.

Agricultural expansion is likely to allow population numbers to increase and geographic range to expand. May be a pest in agricultural crops, and hence control measures may be necessary.

Arvicanthis rufinus RUFIOUS GRASS RAT (GUINEAN GRASS RAT)

Fr. Rat roussard guinéen; Ger. Rote Grasratte

Arvicanthis rufinus (Temminck, 1853). Esquisses sur la côte de Guinée, p. 163. Given as Elmina, Ghana.

Taxonomy Originally described in the genus *Mus*. Long considered as belonging to *A. niloticus* (Rosevear 1969). However, chromosome number distinguishes this species from its sibling species *A. niloticus* and *A. ansorgei* (Civitelli *et al.* 1995, Ducroz 1998, Volobouev *et al.* 2002). Specimens from the Central African Republic with a similar aFN but reduced diploid number (2n = 56, 58; Matthey 1965, Volobouev *et al.* 1987) may belong to this species (Ducroz *et al.* 1998). Shows important genetic divergence from

species in eastern Africa, i.e. *A. niloticus* (as *A. dembeensis*), *A. abyssinicus* and *A. blicki* (Capula *et al.* 1997). Synonyms: *mordax*, *occidentalis*, *setosus*. Subspecies: none. Chromosome number: 2n = 62; aFN = 76 (Volobouev *et al.* 2002).

Description Medium-sized, robustly built rat. Dorsal pelage usually buffy-brown heavily flecked with black; hairs dark brown at base with yellowish to brown-red subterminal band and blackish tip.

Back and flanks tinged with pale red to deep reddish, especially on individuals from the Rainforest BZ (Rosevear 1969). Ventral pelage whitish to grey. Head blunt, short muzzle. Ears rounded and reddish. Digit 5 on forefeet considerably reduced but still functional; Digit 1 vestigial. Soles of hindfoot generally dark. Tail moderately long (ca. 96% and usually shorter than HB), dark above, whitish or pale brown below. Skull: ungrooved upper incisor teeth. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

A. niloticus. Chromosome number: $2n = 62$, aFN = 62–64; more northern distribution.

A. ansorgei. Chromosome number: $2n = 62$, aFN = 74–76; more north-western distribution (Ducroz 1998, Fadda 1998, Volobouev *et al.* 2002).

Distribution Endemic to Africa. Guinea Savanna and Sudan Savanna BZs, and grassy clearings in Rainforest BZ of western West Africa. Distributional limits uncertain; suspected to occur from Sierra Leone (Fadda 1998) to Nigeria, and possibly to Central African Republic. Probably present in Togo and Ghana.

Habitat Grasslands and open clearings in Rainforest BZ (S Benin).

Abundance No information.

Remarks Nothing is recorded about the biology of this species, but it is presumed to be rather similar to that of *A. niloticus* (see above).

Conservation IUCN Category: Least Concern.

GENUS *Colomys* African Water Rat

Colomys Thomas and Wroughton, 1907. Ann. Mag. Nat. Hist., ser. 7, 19: 379. Type species: *Colomys goslingi* Thomas and Wroughton, 1907.

A monotypic genus restricted to the rainforests of central Africa. The single species, *Colomys goslingi*, lives in or close to streams and has a similar life-style to species of *Deomys*, *Malacomys* and *Nilopegamys*. The genus is characterized by woolly pelage, long tail, long hindfeet, long vibrissae, pointed cusps on the cheekteeth and reduced M^3 . Further details are given in the species profile. *Colomys* appears to be closely related to *Zelotomys*; the genera are linked by similarities in cusps on the occlusal surfaces of the cheekteeth, mitochondrial DNA cytochrome *b* sequences and nuclear IRBP gene sequences. The molecular data place *Colomys* and *Zelotomys* with *Myomyscus verreauxii* in a monophyletic cluster, within a larger group composed of *Praomys*, *Mastomys*, *Hylomyscus*, *Heimyscus*, other *Myomyscus* and *Stenocephalemys* (details in Musser & Carleton 2005).

Colomys goslingi.

Fritz Dieterlen

Colomys goslingi.

***Colomys goslingi* AFRICAN WATER RAT (VELVET MOUSE, AFRICAN WADING RAT)**

Fr. Rat aquatique d'Afrique; Ger. Afrikanische Waldbachmaus

Colomys goslingi Thomas & Wroughton, 1907. Ann. Mag. Nat. Hist., ser 7, 19: 380. Gambi, Uele River, DR Congo.

Taxonomy The single species of *Colomys* is widely recognized (Ellerman 1941, Misonne 1969a, Dieterlen 1983, Musser & Carleton 1993). More controversial is the status of *plumbeus*, which has been variously placed as a subspecies of *C. goslingi* (Hayman 1966, Misonne 1974, Dieterlen 1983, Musser & Carleton 1993) or as a full species in its own genus *Nilopegamys* (Kerbis Peterhans & Patterson 1995, Musser & Carleton 2005). Here, *plumbeus* is considered to be a full species (*N. plumbeus*). Another form, *eisentrauti* (here considered to be a subspecies of *C. goslingi*), may also be a valid species, as may be another form (as yet undescribed) from Liberia (R. Hutterer & F. Dieterlen in prep.). Synonyms: *bicolor*, *denti*, *eisentrauti*, *ruandensis*. Subspecies: five. Chromosome number: not known.

Description Medium-sized semi-aquatic rat with dense woolly pelage, white ventral pelage, long tail and very long hindfeet. Pelage dense soft and long; ca. 10 mm on back. Dorsal pelage dark russet-brown; hairs medium grey at base, brown at tip. Flanks slightly paler. Ventral pelage pure white; hairs dense, ca. 5 mm. Colour of ventral pelage clearly delineated from colour of flanks. Head similar in colour to dorsal pelage. Muzzle swollen, dark, with many long (up to 50mm) thick vibrissae. Lips thick, white. Ears relatively short, darkly pigmented, sparsely covered with russet hairs; small subauricular white spot. Chin, throat, lower cheeks, chest, fore- and hindlimbs white. Forefoot with four long digits, Digit 1 rudimentary with a minute nail; five palmar pads, soft and 'pulpy'. Hindfoot long (30–37% of HB), five digits, Digit 5 longer than Digit 4; 5–6 comparatively flat palmar pads. Tail very long (ca. 130% of HB), scaly, dark above with darkish bristles, paler or white below with white hairs; hairs

Skeleton of *Colomys goslingi*.

equally distributed, without lateral fringe but denser and longer towards tip; hairs 4–6 mm. Palatal ridges: $2 + 5 = 7$; the two antemolar ridges continuous, the five intermolar ridges medially interrupted. Skull elongated with relatively small GWS and dorsal-ventral height; cranium comparatively broad and rounded with comparatively large brain and a large foramen magnum; auditory bullae small; incisors large, orthodont; anterior palatal foramina extend posteriorly to at least anterior end of M^1 with expanded interpalatal septum; upper molars rather broad, M^3 remarkably reduced; cones of M^1 and M^2 relatively pointed and upright, resembling those of other (partly) insectivorous murids (Figure 62, see also below). Nipples: $1 + 1 + 2 = 8$.

Figure 62. Skull and mandible of *Colomys goslingi* (BMNH 26.7.6.287).

Colomys goslingi

Geographic Variation Five subspecies have been described; the differences between them are slight and recognition of subspecies is of dubious validity.

- C. g. eisentrauti*: W Cameroon highlands. Large, long-tailed; dorsal pelage dark.
- C. g. bicolor*: Cameroon lowlands. Not as large or dark as *eisentrauti*.
- C. g. goslingi*: South of the Ubangi and Congo rivers. Description as above.
- C. g. ruandensis*: W Rwanda highlands. Smallest form of the genus.
- C. g. denti*: Highlands of Kenya, Uganda and S Sudan. Larger, longer-tailed, blackish-brown, due to many black-tipped hairs especially on back and rump.

Similar Species

- Nilopegamys plumbeus*. Large species, about the size of *Colomys goslingi eisentrauti*; Ethiopia only.
- Malacomys longipes*. Elongated and pointed head, larger ears; Rainforest BZ of central Africa.
- Deomys ferrugineus*. Elongated and pointed head, different in many details; Rainforest BZ of central Africa.

Distribution Endemic to Africa. Rainforest BZ and adjacent Forest–Savanna Mosaics. Distribution disjunct. Recorded from Cameroon, S DR Congo and NE Angola, NE DR Congo, Rwanda, Uganda (Mt Elgon), SW Kenya and S Sudan. Outlier localities in Liberia and NW Zambia. Distribution limits uncertain. Not recorded from Equatorial Guinea, Congo, or Central African Republic, nor in rainforests of West Africa, except Liberia.

Habitat Streams and waterways in primary and secondary rainforest, montane rainforest and gallery forests in savannas. Some individuals may live in non-forested savanna, but never far from the edge of the rainforest. On Mt Elgon, Uganda, two specimens were found in dense

montane forest at 2900 m and one specimen at 3200 m (above the upper altitudinal limit of forest) in a river bed adjacent to *Erica* heathland forest and *Lobelia* swamps. The lowest altitude recorded is about 400 m in the region of Kisangani, DR Congo. Generally records from below ca. 800 m are rare, and it appears that lowland forests are not favoured habitat.

Abundance Uncertain, but probably rare because of its specialized habitat requirements. Single specimens, or – in a few cases – pairs, have been recorded along 100–300 m of stream in montane forest glens. In montane habitats in E DR Congo, comprised 0.5% (n = 5871) of terrestrial small mammals (Dieterlen 1983) and 0.11% (n = 3645) in rainforest near Kisangani, DR Congo (Dudu 1991).

Adaptations Semi-aquatic and nocturnal. African Water Rats (together with *Nilopegamys plumbeus*) are probably the most aquatic-adapted of all African mice. They spend most of the time in or near water. They are buoyant, swimming very rapidly with powerful thrusts of the hindlegs (Kingdon 1974). The pelage is thick and dense (and probably water-repellent). Many of the characters of the species are associated with life in and close to water: the long limbs hold the body out of the water when paddling in shallow water, the hairs on the tail probably assist in better swimming and steering, the broad hindfoot provides effective power for propulsion when swimming, and the splayed digits and prominent palmar pads enable locomotion on soft mud.

An interesting character of *Colomys* is the relatively large brain compared with that of other similar-sized rodents, and the enlarged foramen magnum. Studies by Stephan & Dieterlen (1982) showed that estimated brain weight in relation to body weight was about 132% above expected, and comparatively heavier than in 17 other species of murid rodents. Likewise the area of the foramen magnum was about 127% greater than expected, and larger than in the other

murid rodents. Such enlargement in brain size is presumed to be associated with the complex behaviour patterns associated with an aquatic predatory life-style, as is seen also in *Potamogale* spp. (Potamogalinae: Tenrecidae) and *Malacomys* spp. (Rodentia: Muridae).

The muzzle is bulbous and swollen. The muzzle and thick upper lips have numerous thick dark vibrissae, which fan out around the mouth, and are assumed to be a very special adaptation for searching and detecting live animal food in the water (Kingdon 1974, Dieterlen 1983). When searching for food from the edge of the water, or while wading in water, the nose is held close to the water surface with the vibrissae spread out and dipped into the water. The muzzle has a highly developed sensory system, which is perceptive to the slightest vibrations (Stephan & Dieterlen 1982). Another adaptation, important for the mobility of the muzzle, is the remarkable long bony projection between the upper incisors, which is probably an insertion point for special muscles (Dieterlen 1983).

Foraging and Food Carnivorous. Observations of individuals in captivity show that they forage by actively hunting prey in the water and by filtering water through the vibrissae. They can capture tadpoles and small fish in complete darkness, probably by detecting small vibrations or water movement (Dieterlen & Statzner 1981). Aquatic invertebrates (which form the majority of the food – see below) are probably hunted in the same manner. A second method of obtaining prey is by sifting mud and debris in shallow water with the forelimbs; disturbed prey is detected by the muzzle and vibrissae, which are held just below the water surface (Kingdon 1974). A final method is by using the long vibrissae on the muzzle (which are spaced about 0.5 mm apart) as a net, which can filter food (such as the exuviae of insects) floating on or near the surface (Dieterlen & Statzner 1981). The vibrissae (and perhaps other tactile or sensory receptors on the muzzle) are clearly important in detecting and catching food, although their precise role in foraging is uncertain.

Stomach analysis (n = 15) shows that the diet is mainly benthic invertebrates, principally the larval stages of Trichoptera; other foods include larval and adult Coleoptera, larval Diptera, larval Plecoptera and larval Odonata (Dieterlen & Statzner 1981). The diet of each individual showed considerable variation, which suggests that feeding is opportunistic and dependent on location and availability; 85% of identified food items (n = 294) were aquatic in origin and

ca. 12% were of terrestrial origin. Occasionally snails, spiders and plant material were eaten.

Social and Reproductive Behaviour Trapping data suggests that they live singly or in pairs, well spaced out along the length of streams. No detailed information available.

Reproduction and Population Structure Most pregnant ♀♀ and young animals recorded in Sep–Mar/Apr in Kivu, E DR Congo (Dieterlen 1983). Embryo number: 2.09 (1–3, mode 2, n = 11). Females and ♂♂ become mature and sexually active when ca. 50 g. In adult ♂♂ testes length varied from 8 to 14 mm, possibly due to seasonal changes.

Predators, Parasites and Diseases Known predators include buzzards (Kingdon 1974) and African Grass-owls *Tyto capensis* (Ansell 1965). They also may be preyed upon by snakes and the Marsh Mongoose *Atilax paludinosus*, which may be common close to streams (Kingdon 1974).

Conservation IUCN Category: Least Concern.

Schlitter (1989) classified the species as ‘Rare’.

GENUS *Dasymys*

Shaggy Rats

Dasymys Peters, 1875. Monatsber. K. Preuss. Akad. Wiss. Berlin, p. 12. Type species: *Dasymys gueinzii* Peters, 1875 (= *Mus incommisus* Sundevall, 1847).

The genus *Dasymys* is endemic to Africa and is represented by five species intermittently distributed from Senegal to Ethiopia and southwards to the Cape region of South Africa. Shaggy Rats live in wetland environments, from sea level to 4000 m, where dense ground cover affords suitable habitat for runways and nests. Their distribution is accordingly patchy, and none of the species occurs in the Sahel Savanna, Somalia–Masai Bushland and South-West Arid BZs. Their semi-aquatic habits, and association with wetlands, account for the other common names applied to the species – Marsh Rats, Swamp Rats, or Water Rats.

Shaggy Rats are medium to large in size, and aptly named in view of the sometimes rumpled appearance imparted by their long, soft, lax pelage and dense underfur. The dorsal pelage is dull brown to greyish-brown and rather drab; the flanks often brighter, buffy-brown to silvery-grey; and the ventral pelage is pale whitish-buff. They have short, rounded ears, narrow hindfeet with short Digits 1 and 5, and relatively long tails (ca. 75–95% of HB).

The skull is distinguished by the following characters: robust with a greatly constricted interorbital constriction that is narrower than

Dasymys incomptus.

the rostrum; supraorbital edges reflected dorsally as a sharp bead that flattens and merges with temporal ridge. Rostrum moderate in length and width but deep. Zygomatic arches stout over anterior portion; zygomatic plate moderately wide, leading edge concave. Braincase elongate, temporal and lambdoidal ridging present but weakly defined. Anterior palatal foramina long (ca. 70–75% of diastema length), terminating posteriorly between the anterior roots of first molars. Toothrows close set and slightly convergent anteriorly, hard palate correspondingly compressed with low medial ridge. Parapterygoid fossae moderately recessed, and alisphenoid strut absent. Auditory bullae moderately sized. Molars stoutly proportioned and broad with M^3 as long as M^2 . Cusps heavy and blunt, individually defined in young animals but tending to unite transversely after moderate wear. Cusp $t3$ of M^1 small and weakly delineated from $t2$; $t3$ of M^2 usually absent, rudimentary if present; M_{1-2} without $t7$, $t9$ and posteroloph. Unlike *Otomys* spp., M^3 is not the longest molar tooth and the cheekteeth do not have multiple lamellae. Anteromedian and posterolabial conulids typically present on m_1 , anterolabial conulid well defined on m_2 ; posterolophid (postcingulum) absent on m_{1-2} . Molar root formula: $5-6/5, 4/4, 3/3$. Upper incisors broad and not grooved, opisthodont to nearly orthodont, enamel surface pale to deep orange (Figure 63).

The nearest generic relatives of *Dasymys* remain obscure. Ellerman (1941) viewed the genus as most closely related to *Arvicanthis*, and

Figure 63. Skull and mandible of *Dasymys incomptus* (HC 2780, BMNH 52:1579).

Misonne (1969a) included *Dasymys* as a member of the *Arvicanthis* Division without further comment on its kinship. A close relationship between *Dasymys* and *Aethomys* has been suggested by Denys (1990c) based on dental similarities to a South African Pliocene fossil (*A. adamanticola*). In studies using albumin microcomplement fixation data (Watts & Baverstock 1995a) and mitochondrial DNA sequences (Ducroz *et al.* 2001), *Dasymys* is portrayed as cladistically strongly divergent from arvicanthines in the strict sense. Such a mixture of viewpoints invites further phylogenetic study that draws upon broader taxonomic sampling and other information sources.

No subgenera recognized. Several species had been acknowledged until Ellerman (1941) arranged most named forms as subspecies

Table 31. Species in the genus *Dasymys*. Arranged according to increasing mean head and body length.

| Species | HB mean (range) (mm) | T mean (range) (mm) [% of HB] | HF mean (range) (mm) | GLS mean (range) (mm) | Dorsal pelage | Notes |

^a Distribution uncertain; see text for further details.

of a highly variable *D. incommutus*. Recent regional studies have demonstrated that this view of lack of diversity is overly simplistic, resulting in the reinstatement of several species (Crawford-Cabral & Pacheco 1989; Carleton & Martinez 1991).

Criteria for species recognition have emphasized slight but consistent differences in external and cranial size, degree of molar robustness, relative length of tail, and occurrence of a sixth (hypothenar) plantar pad. The usefulness of karyotypic differences for specific identification requires further study but appears to be promising (see Gordon 1991, Volobouev *et al.* 2000). Species

allocation of populations in the Congo Basin is uncertain and requires further investigation (see *D. incommutus*, *D. rufulus*). Verheyen *et al.* (2003) described three new species based on craniometric and genetic data (*D. cabrali* [Caprivi Strip region, NE Namibia], *D. sua* [near Morogoro, Tanzania] and *D. ruandae* [Kinigi and district, Rwanda]), all of which are here included within the range of '*D. incommutus*'.

Five species (*D. foxi*, *D. incommutus*, *D. montanus*, *D. nudipes* and *D. rufulus*) are recognized here (Table 31).

Michael D. Carleton

Dasymys foxi Fox's SHAGGY RAT

Fr. Rat hirsute de Fox; Ger. Foxs Wollhaarratte

Dasymys foxi Thomas, 1912. Ann. Mag. Nat. Hist., ser. 8, 9: 685. Panyam, Nigeria. 4000 ft (1220 m).

Taxonomy Although described as a species (Thomas 1912a), *foxi* was later re-allocated as a race of a widely ranging *D. incommutus* by Ellerman (1941), whose classification was long observed in regional works (Rosevear 1969, Happold 1987). Based on morphometric evaluations, Carleton & Martinez (1991) considered *foxi* to be a species distinct from other West African *Dasymys*. Synonyms: none. Chromosome number: not known.

Description Large-sized rodent with long shaggy pelage; large for the genus but smaller than *D. nudipes*. Dorsal pelage warm buffy-brown; hairs plumbeous-grey on basal two-thirds, bright buff on distal third; guard hairs dusky-brown. Flanks grading to paler buffy-brown or greyish-brown. Ventral pelage pale to dark grey, usually with a creamy-buff wash; hairs plumbeous-grey at base, white at tip. Ears small and rounded, with medium brown hairs. Dorsal surface of fore- and hindfeet pale brown. Tail long (ca. 85% of HB), uniformly dark brown; caudal hairs short, exposing moderately

coarse scales. Six plantar pads on hindfoot, hypothenar pad small but normally present. Skull: stoutly built (GLS ca. 35–38 mm), broad across braincase and zygoma; molars robust. Upper incisors not grooved. Sexual dimorphism in cranial size not detected within a large population sample (Carleton & Martinez 1991). Nipples: 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species

D. rufulus. Dorsal pelage having more reddish-brown tones; on average slightly smaller in most external and cranial dimensions; more broadly distributed in West Africa.

Distribution Endemic to Africa. Guinea Savanna BZ. As currently understood, restricted to the Jos Plateau, central Nigeria (Carleton & Martinez 1991).

Habitat Marshy area, with tall, dense grasses and sedges, bordering a stream on the Jos Plateau (an isolated elevated area of grasslands and rocks – see Happold 1987).

Abundance No information. Known only from the region of the type locality.

Remarks Very little is known about this species. Described as a 'water rat' and 'a great swimmer' by Reverend G. T. Fox, the collector of the type series (Thomas 1912a).

Conservation IUCN Category: Data Deficient.

Dasymys incommutus COMMON SHAGGY RAT

Fr. Rat hirsute Africain; Ger. Afrikanische Wollhaarratte

Dasymys incommutus (Sundervall, 1847). Ofv. K. Svenska Vet.-Akad. Forhandl, Stockholm 3: 120 (1846, publ. 1847) 'Caffraria prope portum Natal' (= Durban, South Africa).

Taxonomy Originally described in the genus *Mus*. Ellerman (1941) included all named forms of *Dasymys* within this species, either as subspecies or synonyms (see Genus profile). The current viewpoint is to regard the genus as a complex of several species (Musser & Carleton 1993, 2005). Rosevear (1969) recorded *D. incommutus* from West Africa, recognizing three subspecies: *rufulus* (now a valid species), *foxi* (now a valid species) and *longipilosus* (now a synonym of *D. rufulus*). Thus, on these criteria, *D. incommutus* is now restricted to forms found only in eastern, central and southern Africa. However, Mullin *et al.* (2002, 2004) restricted *D. incommutus* to populations in Zimbabwe and South Africa, and considered those in the Congo Basin, shown here (see map) as *D. incommutus*, to belong to a different species. On the basis of canonical analyses of skull shape, Mullin *et al.* (2004) suggested that populations from most of the northern range of *D. incommutus* represent part of the *D. rufulus* complex (see *D. rufulus* profile), that some populations in Zimbabwe, NE Botswana and N South Africa represent their new species *D. robertsi*, and that those in N Botswana represent another new species *D. shortridgei*. A further complexity regarding the definition and distribution of *D. incommutus* is provided by Verheyen *et al.* (2003) who referred confusingly to *bentleyi* in the Congo Basin, a taxon that may be considered either as a valid species, or as a subspecies of *D. incommutus*; these authors also described three new species (see Genus profile) whose distributions are within the geographic range of *D. incommutus* as mapped here. Synonyms: *bentleyi*, *capensis*. Subspecies: three. Chromosome number: not known.

Description Large shaggy rat, stoutly built with long tail. Pelage soft and shaggy, with distinct sheen; dorsal hairs 13–15 mm. Dorsal pelage dark grey to black; hairs dark grey at base, blackish-brown at tip. Ventral pelage dull grey; hairs pale grey at base, buffy-white at tip. Head broad, muzzle short. Vibrissae long. Eyes small. Ears broad and round, well-furred on inner surface. Fore- and hindfeet brown, almost hairless; claws long and white; typically six plantar pads. Tail long (ca. 90% of HB), heavily scaled, sparsely haired, dark above, pale below. Pelage of juveniles darker and woollier than adults. Skull with extreme interorbital constriction. Upper incisors not grooved. Nipples: 1 + 2 = 6.

Geographic Variation Three subspecies may be recognized (see Meester *et al.* 1986):

D. i. incommutus: E South Africa and possibly Mozambique. Dull buffy-brownish pelage; smaller than *D. i. capensis*.

D. i. bentleyae: N Angola and DR Congo. Smaller than *D. i. nudipes*.

D. i. capensis: SW South Africa. Dark pelage, pale yellow incisors, heavy mandible, short anterior palatal foramina; mandible oval shape between condyle and coronoid arch.

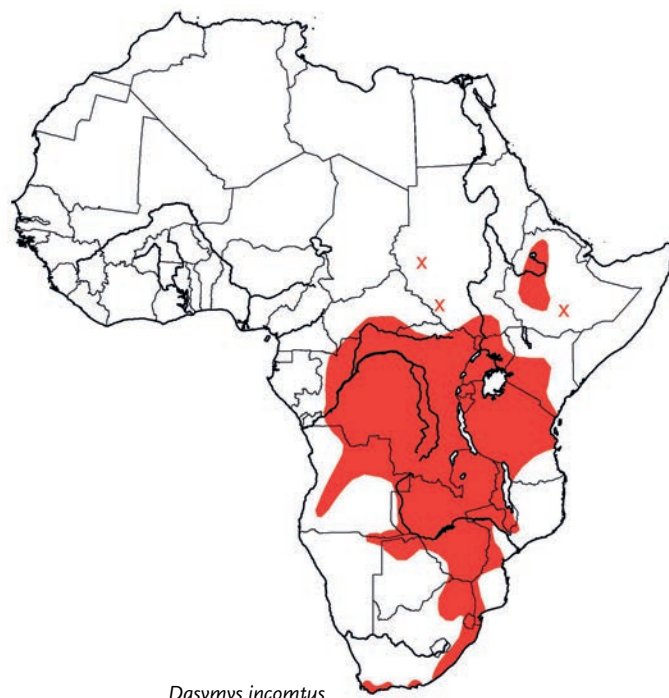

Similar Species

D. montanus. Pelage dark brown, tending to black dorsally; Rwenzori Mts, Uganda.

D. nudipes. Pelage olive-brown, blackish-brown dorsally; typically five plantar pads on hindfoot; on average larger body size and variation in configuration of interparietal bone; S Angola, N Botswana and W Zambia.

Otomys spp. Shorter tails (ca. 60% of HB); upper incisors with grooves.

Distribution Endemic to Africa. Widely distributed, but patchily (see Habitats) in Zambezian Woodland BZ and Rainforest BZ (East Central and South Central Regions), and marginally in southern part of Somalia–Masai BZ. Recorded in eastern, central and southern Africa, including S Sudan, Ethiopia, DR Congo, Uganda, Kenya,

Dasymys incommutus

Tanzania, Angola, Zambia, Malawi, Zimbabwe and South Africa (Musser & Carleton 1993).

Habitat Reed-beds, long grass close to water, semi-aquatic vegetation and marshes. Normally found close to water or damp vegetation, including drainage lines.

Abundance Despite their widespread distribution, African Shaggy Rats are rarely caught and are believed to occur at low densities (Smithers 1986b).

Adaptations Terrestrial and semi-aquatic. Shaggy Rats swim well and readily take to water; swimming is a 'dog-paddle' and is already developed before weaning (ca. Day 12; Pillay 2003). Predominantly crepuscular and diurnal (southern Africa; Smithers 1975). Nests of African Shaggy Rats in Malawi (Hanney 1965) were built 2–20 m from water; each nest consisted of two parts, an upper part on the surface of the ground and a lower part in a depression. Entrance to the nest was concealed in the depression, and led to well-defined runs. In two nests, the entrance led to an underground burrow that opened below water level. Nests are built of intricately woven grasses and other local materials.

Foraging and Food Predominantly herbivorous. The diet comprises a wide range of aquatic and semi-aquatic plants, although insect remains have been found in stomachs (Hanney 1965, Smithers 1975). In captivity, Shaggy Rats eat mealworms and a variety of fruit and vegetables.

Social and Reproductive Behaviour In captivity, both sexes are aggressive, suggesting a solitary life-style in the wild; ♀♀ tolerate unfamiliar ♂♂ only when they are in oestrus (Pillay 2003). The social organization and mating system are unknown.

Reproduction and Population Structure Seasons and months when reproduction occurs vary widely throughout geographic range. In Botswana and Zimbabwe, reproduction occurs during the warm wet season (Aug–Mar; Smithers 1975); a single pregnant and lactating ♀ was found in KwaZulu–Natal, South Africa in winter (Jun; Taylor 1998); and pregnant ♀♀ were recorded in the dry season in Malawi (Jun and Aug; Hanney 1965). Lactation recorded in Apr in Tanzania (Allen & Loveridge 1933). Females have spontaneous ovulation, and an oestrus cycle of 8 days (range 7–16;

Pillay 2003). Gestation (in captive population): ca. 29 days (Pillay 2003). Litter-size: 2–4 over geographic range (Allen & Loveridge 1933; Hanney 1965; Delany 1969; Kingdon 1974). Litter-size: 5 (2–9; South Africa; De Graaff 1981). At birth, young are altricial, weight ca. 8 g. Weaned ca. Day 24. Young nipple-cling until Day 30. Onset of sexual maturity in ♂♂ ca. Week 6, and first mating Week 8. First complete oestrus cycle and conception in ♀♀ ca. Week 18–19, suggesting that only ♀♀ born early in the breeding season are likely to reproduce in the season of their birth.

Predators, Parasites and Diseases Remains found in owl pellets (Hanney 1965, Happold & Happold 1986). Captured by humans for food in some parts of Malawi (D. C. D. Happold unpubl.). Ectoparasites include seven species of fleas, 28 species of mites and one species of tick; endoparasites include two species of platyhelminth worms (details in De Graaff 1981). Specimens in DR Congo have been found with large numbers of schistosome worms, which cause bilharzia in humans (Schwetz 1956).

Conservation IUCN Category: Least Concern.

Widespread with a wide geographic range. Shaggy Rats are associated with rivers and wetlands, and hence wetland destruction will reduce their geographical range and population numbers.

Dasymys montanus MONTANE SHAGGY RAT

Fr. Rat hirsute de montagne; Ger. Montane Wollhaarratte

Dasymys montanus Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 143. Mubuku Valley, Rwenzori East, Uganda. 12,500 ft (3810 m).

Taxonomy Like many other forms of *Dasymys*, Thomas's (1906) *montanus* was synonymized in Ellerman's (1941) broad polytypic treatment of *D. incommutus* and followed by later authors (e.g. Delany 1975). However, Thomas's original diagnosis was well founded (see Musser & Carleton 1993), because he also examined specimens of a larger *Dasymys* from the lower slopes of Rwenzori that he named (in the same paper) as *D. medius*, now considered to be a synonym of

D. incommutus. Whether *D. montanus* is limited to the Rwenzori Mts or occurs on other western Rift Valley mountains is uncertain. Synonyms: none. Chromosome number: not known.

Description Medium-sized, long-haired shaggy rat with a short tail. Pelage long and thick, texture very fine and soft. Dorsal pelage satiny dark brown, finely speckled with buff, more blackish

over mid-dorsum and slightly paler toward flanks; hairs dark grey at base, buff at tip. Ventral pelage slaty-grey. Ears short, heavily clothed with black hairs. Plantar pads six. Tail short (ca. 70% of HB), relatively the shortest in the genus, uniformly black. Skull small in most dimensions, about the size of *D. rufulus*, but zygomatic arches comparatively broad and auditory bullae large; interorbital ridges weakly developed. Upper incisors not grooved. Nipples: not known.

Geographic Variation None recorded.

Similar Species

D. incomtus. Similar in general appearance; on average larger in all body measurements and GLS; tail relatively longer (ca. 90% of HB); very widespread; although sympatric, probably not syntopic; occurs at lower altitudes.

Distribution Endemic to Africa. Afroalpine–Afroalpine BZ. So far known only from high altitudes (2600–4300 m) in the Rwenzori Mts of W Uganda and perhaps neighbouring DR Congo.

Habitat Afroalpine and subalpine habitats such as dense grassy slopes, fern-covered glades, sphagnum moss–lobelia bogs, and open moorland (Kerbis Peterhans *et al.* 1998; FMNH field notes).

Abundance Comprised 1–10% of small rodent captures (n = 69–175) at three localities (2700–3400 m) in Rwenzori Mountains N. P., Uganda; uncommonly captured compared to other syntopic species such as *Hylomyscus denniae* (32–51%) and *Lophuromys flavopunctatus* (25–43%) (Kerbis Peterhans *et al.* 1998). The highest percentage abundance was at the highest locality.

Remarks Trapping results suggest both diurnal and nocturnal activity (Kerbis Peterhans *et al.* 1998). Herbivorous; reported to feed on flower blossoms and succulent stems of new rushes (Thomas & Wroughton 1910). None of four ♀♀ taken in the wet season (Nov–Dec) or dry season (Apr–May) was visibly pregnant (Kerbis Peterhans *et al.* 1998).

Conservation IUCN Category: Endangered.

The species has a very small known geographic distribution, although the high altitude habitats where it occurs are relatively unaffected by human activities.

Dasymys nudipes ANGOLAN SHAGGY RAT

Fr. Rat hirsute d'Angola; Ger. Angolanische Wollhaarratte

Dasymys nudipes (Peters, 1870). Journ. Sci. Math. Phys. Nat., Lisboa, ser. 1, 3: 126. Huilla (= Huila), Angola.

Taxonomy Originally described in the genus *Mus*. Retained as a species as originally described until Ellerman (1941) reassigned *nudipes* as a subspecies of *D. incomtus*, a classification conventionally accepted throughout the mid-1900s (Ellerman *et al.* 1953, Misonne 1974; Honacki *et al.* 1982). However, based on morphological differences, the specific status of *nudipes* was restored by Crawford-Cabral (1983) and Crawford-Cabral & Pacheco (1989). The status and relationships of populations in SE Angola (Crawford-Cabral

1998), N Botswana (Smithers 1971) and SW Zambia (Ansell 1978), formerly assigned to *D. incomtus nudipes*, warrant re-evaluation. *Dasymys nudipes* may prove to be a species limited to the Angolan highlands (especially see Crawford-Cabral & Pacheco 1989). Synonyms: none. Chromosome number: not known.

Description Large shaggy rat, the largest in the genus. Dorsal pelage drab olive-brown, blackish-brown on middle dorsum,

sometimes iridescent; hairs dark plumbeous with short dull ochraceous tip; guard hairs blackish. Flanks with more buff than on back. Ventral pelage dull grey; hairs dark grey at base, dull white at tip. Ears darkly pigmented, short and hairy. Upper surface of hindfeet thinly furred, short brown hairs on tarsus-metatarsus and dull white on digits; typically five plantar pads on hindfoot, the lateral metatarsal pad (hypothenar) usually absent. Tail long (ca. 95–98% of HB), relatively the longest for the genus; uniformly dark brown to blackish, scale pattern moderately coarse, caudal hairs very short and indistinct. Skull and dentition robust (GLS: ca. 37–43 mm); rostrum relatively long; auditory bullae comparatively and relatively large. Cusp t3 of M^2 typically lacking. Upper incisors not grooved, anterior face burnt orange. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

D. incomtus. On average smaller; HF shorter (ca. 30–35 mm); dorsal pelage with more reddish-brown; plantar pads typically six; tail shorter and relatively shorter; skull less robust (GLS: ca. 34–41 mm) and molar row shorter (M^1 – M^3 : <7.4 mm).

Distribution Endemic to Africa. Restricted areas of Zambezan Woodland BZ. Distribution, as currently understood, disjunct: (a) plateau of WC Angola; (b) the Okavango and Chobe river systems of SE Angola, Caprivi Strip and N Botswana, and W Zambia (Smithers 1971, Ansell 1978, Crawford-Cabral 1998). Possibly also occurs between these two areas.

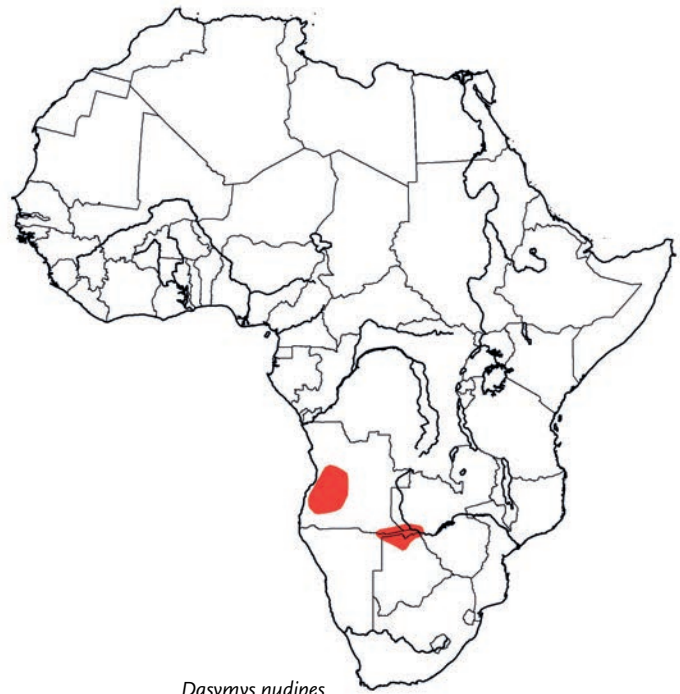

Habitat Reeds, sedges and semi-aquatic grasses bordering rivers and streams, swamps and marshland, especially where fallen leaves and other litter form a matted surface amongst dense wetland ground cover (Botswana; Smithers 1971).

Abundance No information.

Adaptations Terrestrial and semi-aquatic. Described as mainly nocturnal with limited diurnal activity. Constructs domed nests of cut grass and other vegetation, placed at ground level with a short refuge tunnel nearby (Botswana; Smithers 1971).

Foraging and Food Herbivorous and occasionally insectivorous. Feeds on fresh shoots and stems of reeds and semi-aquatic grasses, and other unidentifiable vegetable matter. Insect parts reported in some stomachs. Runways formed between nests and regular feeding areas are littered with fresh remains of severed reeds and grasses (Botswana; Smithers 1971).

Social and Reproductive Behaviour No information.

Dasymys nudipes

Reproduction and Population Structure Males with scrotal testes and lactating ♀♀ recorded in Aug and Nov (Angola; Hill & Carter 1941). Gravid ♀♀ and nestling young recorded in late dry to late wet season (Aug–Mar); litter-size: 5.3 (2–9, $n = 4$; Botswana; Smithers 1971).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Data Deficient.

Dasymys rufulus RUFIOUS SHAGGY RAT

Fr. Rat hirsute roux; Ger. Rote Wollhaarratte

Dasymys rufulus Miller, 1900. Proc. Washington Acad. Sci., 2: 639. Mount Coffee, Liberia.

Taxonomy Referred to as *D. incommutus rufulus* in previous studies (e.g. Rosevear 1969; Happold 1987). Following Carleton & Martinez (1991) and Musser & Carleton (2005), *rufulus* is considered here to be a valid species restricted to West Africa. Musser & Carleton (1993, 2005) recorded that the geographic range extends from Senegal to Cameroon and that the species of *Dasymys* in DR Congo and further east and south is *D. incommutus*. Previous studies suggested that *D. rufulus* is also the correct name for the populations of central and eastern Africa, formerly considered to be *D. incommutus* (Mullin *et al.* 2004). Moreover, morphometric evidence suggests that *D. rufulus* consists of five subgroups (possibly cryptic species) that replace one another geographically: (1) western West Africa (Senegal to SE Côte d'Ivoire); (2) eastern West Africa (SE Côte d'Ivoire to Nigeria and Chad); (3) central Africa (Cameroon, Congo, DR Congo); (4) central and East Africa (N Angola, Zambia, S Malawi, W Mozambique, Sudan); and (5) south central Africa (STanzania, N Malawi and Mozambique) (Mullin *et al.* 2004). Other techniques (e.g. DNA, chromosome analysis) should be used to further examine the relationship within *D. rufulus* with respect to these five subgroups. The subspecies, *D. i. longipilosus*, described from Mt Cameroon by Eisentraut (1963), is considered to be a valid species by Mullin *et al.* (2004) but a synonym of *D. rufulus* by Musser & Carleton (1993, 2005) and here. Synonyms: *longipilosus*. Subspecies: none. Chromosome number: $2n = 36-39$; $aFN = 44-50$ due to the presence of 0 to 3 B chromosomes (Volobouev *et al.* 2000).

Description Medium-sized stout rodent with soft dense shaggy pelage. Dorsal pelage brown to grey-brown with rufous tinge on mid-back, especially on rump; hairs dark grey with rufous tip. Underfur very fine and dense. Flanks brown, hairs with buff tip. Ventral pelage paler, hairs grey with dull white or whitish-buff tip. Colours of dorsal and ventral pelage merge on flanks. Head similar in colour to dorsal pelage; rufous tinge extends to tip of muzzle. Eyes dark, comparatively small. Ears small, rounded, densely covered with short rufous-brown hairs. Ears and eyes often hidden by hair. Limbs short. Forefoot with four digits; Digit 1 vestigial, Digit 5 short. Hindfoot with five digits; Digits 1 and 5 short, Digits 3, 4 and 5 long. Tail long (ca. 100% of HB), ringed with small scales, and with sparse very short dark bristles. Upper incisors not grooved. Nipples $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

D. foxi. Larger in most body and cranial measurements; pelage buffy-brown or greyish-brown; restricted to Jos Plateau, Nigeria.

D. incommutus. Larger in most body and cranial measurements; pelage dark without reddish-brown or rufous tinge; southern and eastern Africa.

Distribution Endemic to Africa. Guinea Savanna BZ, Northern Rainforest–Savanna Mosaic, and Rainforest BZ of West Africa; may

*Dasymys rufulus*

extend into Sudan Savanna BZ in some regions. Recorded from S Senegal (south of Gambia), Guinea-Bissau, Guinea, Sierra Leone, Liberia, Côte d'Ivoire, Ghana, Togo, Benin, Nigeria and S Mali (Volobouev *et al.* 2000) and S Burkina (Gautun *et al.* 1985). One locality in Cameroon. Two isolated populations, north of the Gambia R. in Senegal (Duplantier *et al.* 1997). Following Mullin *et al.* (2002) and Mullin *et al.* (2004), the geographic range is far greater and includes parts of the Somalia–Masai and Zambezian Woodland BZ and the Southern Rainforest–Savanna Mosaic, and hence Congo, DR Congo, N Angola, Zambia, Malawi, W Mozambique, Sudan and Tanzania (see comments in genus and *D. incommutus* profiles).

Habitat Stream and river banks, marshy areas and swampy edges along rivers and lakes, wetter parts of flood-plains, young oil palm plantations, and rice fields.

Abundance Locally abundant in suitable habitats. Comprised 14.6% of the rodents trapped in grasslands at Mt Nimba (Guinea), 9.2% in savannas at Bolo and 7.5% in savannas at Lamto (Côte d'Ivoire), but only 0.5% in Adiopodoumé (Côte d'Ivoire) and 0.07% in Taï forest (Côte d'Ivoire) (Gautun *et al.* 1986). The most abundant rodent in young oil palm plantations in Côte d'Ivoire (trap success: 3.5–19.5% compared with 1–3% in nearby savannas), but uncommon in mature and old plantations (Bellier *et al.* 1964).

Adaptations Nocturnal (Duplantier & Granjon 1990). Very good swimmer (Duplantier & Bâ 2001). Occupies shallow burrows at the foot of grass tussocks (Coe 1975).

Foraging and Food Herbivorous. Feeds mainly on grasses and leaves (Coe 1975).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Gestation: 32 days (Gautun 1972). Mean embryo number: 3.22 ($n = 31$ ♀♀; Côte d'Ivoire; Bellier *et al.* 1964). In captivity, litter-size: 2.8 (2–3, $n = 8$; $n = 6$ in Côte d'Ivoire [Gautun 1972] and $n = 2$ in Senegal [J.-M. Duplantier unpubl.]).

Predators, Parasites and Diseases Remains found in pellets of Barn Owls *Tyto alba* in Guinea-Bissau (Heim de Balsac 1965) and Niayes region, Senegal (L. Granjon, K. Bâ and J.-M. Duplantier, unpubl.).

Conservation IUCN Category: Least Concern.

GENUS *Dephomys*

Defua Rat

Dephomys Thomas, 1926. Ann. Mag. Nat. Hist., ser. 9, 17: 177. Type species: *Mus defua* Miller, 1900.

Dephomys defua.

A monotypic genus restricted to rainforest habitats in the Western Region of the Rainforest BZ. Although rather similar to *Stochomys* in external characters, its relationship to *Stochomys* is uncertain and is maybe more closely related to *Hybomys* (subgenus *Hybomys*) than to *Stochomys* (Musser & Carleton 2005). Appears to be the ecological equivalent to *Stochomys* in the rainforests of the Western Region (where *Stochomys* is not present). Distinguished from *Stochomys* by overall smaller size (smaller mean values, often non-overlapping measurements), thinner anterior palatal foramina, wider palate (relative to width of M^1) and smaller M^1 . Additional information is given in the species profile (see also Rosevear 1969). The single species is *Dephomys defua*.

D. C. D. Happold

Dephomys defua DEFUA RAT

Fr. Rat cible de Defua; Ger. Defua-Ratte

Dephomys defua (Miller, 1900). Proc. Washington Acad. Sci. 2: 635. Mt Coffee, Liberia.

Taxonomy Originally described in the genus *Mus*, and subsequently allocated to *Rattus* (Heim de Balsac & Bellier 1967), *Stochomys* (Misonne 1974) and *Dephomys* (Thomas 1926, Rosevear 1969, Van der Straeten 1984, Grubb *et al.* 1998). The subspecies *eburneae* from Côte d'Ivoire (Heim de Balsac & Bellier 1967) is considered (on the basis of canonical analysis) to be a valid species by Van der Straeten (1984) and Musser & Carleton (1993, 2005), but is considered here to be a subspecies of *D. defua*. Synonyms: *eburneae*. Subspecies: two. Chromosome number: $2n = 54$ (SW Côte d'Ivoire; *D. d. defua*?); $2n = 44$ ($n = 1$; Soubré, SW Côte d'Ivoire), $2n = 42$ (E Côte d'Ivoire; *D. d. eburneae*?) (Tranier & Dosso 1979). Variation in chromosome number in relation to distribution and taxonomic status requires investigation; Tranier &

Dosso (1979) suggest that different karyotypes may occur in different forest sub-regions – one to the west (i.e. Liberian Sub-region) and one to the east (i.e. Ghanaian Sub-region).

Description Medium-sized rat with very long tail similar to *Stochomys longicaudatus*. Pelage fairly long (ca. 10 mm) and coarse. Dorsal pelage brown to reddish-brown; hairs dark grey at base, reddish-brown at tip. Rump colour sometimes brighter (orangy-red) than mid-back. Long black guard hairs, often with pale tips, on rump. Ventral pelage whitish-grey; hairs dark grey at base, white or greyish-white at tip. Head long and pointed. Ears small, sparsely haired and rounded. Long dark vibrissae. Upper surfaces of fore- and

Figure 64. Skull and mandible of *Dephomys defua* (RMCA A2167).

Dephomys defua

hindfeet white or pale brown. Forefeet with four digits, each with small claw; Digit 1 absent. Hindfeet broad; five digits, Digits 1 and 5 shorter than Digits 2–4; each digit with small claw. Tail very long (ca. 154% of HB), dark, appears naked, but with rings of small scales and small bristles. Skull: incisors not grooved; supraorbital ridges well developed; auditory bullae small; anterior palatal foramina small and narrow, not reaching anterior end of M^1 ; width of palate at level of M^1 at least 1.5 times width of M^1 ; molar teeth rather weak; t_7 on M^1 absent; t_9 of M^1 present and moderately well developed; t_3 on M^2 very reduced and displaced (Figure 64). Nipples: $0 + 2 = 4$.

Geographic Variation Two subspecies, distinguishable mainly by canonical analysis (Van der Straeten 1984):

D. d. defua: recorded from Sierra Leone, Guinea (Mt Nimba) and Liberia.

Description as above; t_3 of M^1 present, but variable in structure.

D. d. eburneae: recorded in Côte d'Ivoire and Liberia. t_3 of M^1 reduced or absent; t_9 of M^1 reduced. Musser & Carleton (2005) regard this taxon as a valid species.

Similar Species

Stochomys longicaudatus. On average larger body measurements; similar externally, black guard hairs longer and more numerous, covering most of dorsal pelage; skull longer (mean GLS ca. 39 mm; mean M^1 – M^3 ca. 6.4 mm); t_9 on M^1 reduced to small displaced cusp; t_3 on M^2 very reduced and displaced; nipples $1 + 2 = 6$; allopatric (forest relics in Dahomey Gap and rainforests from Nigeria to E DR Congo). *Grammomys kuru*. Similar size; mainly arboreal; ventral pelage pure white; guard hairs not present; hindfoot narrower.

Distribution Endemic to Africa. Rainforest BZ (Western Region). Recorded from Sierra Leone, Guinea (Mt Nimba), Liberia, Côte d'Ivoire and Ghana.

Habitat Rainforest, swampy areas in rainforest, forest clearings and secondary growth. Also recorded in cocoa plantations (Jeffrey 1975) and oil palm plantations (Bellier 1964). On Mt Nimba, found in undisturbed forest, secondary scrub and grasslands (Coe 1975). Recorded very occasionally (2%, $n = 96$) in sacred groves (isolated patches of forest) in eastern region of Ghana (Decher 1997).

Abundance Rare or uncommon. At four rainforest sites in Ghana, comprised ca. 10% of small mammals ($n = 270$, 6 spp.; Cole 1975). In immature cocoa plantations, where *Praomys tullbergi* and *Lophuromys sikapusi* were the main species, only one individual was found ($n = 98$; 10 spp.), and in natural clearings in rainforest, only four were encountered ($n = 110$; 8 spp.) (Jeffrey 1977).

Remarks Nocturnal. May be partly arboreal. Diet is primarily vegetable material and some insects, and is similar to that of syntopic *Praomys tullbergi* and *Hylomyscus stella* (Cole 1975). Slugs and earthworms are not eaten (cf. *Malacomys* spp., Cole 1975). One pregnant ♀ in Ghana had two embryos (Jeffrey 1975; date not recorded), lactating ♀♀ were recorded in Taï N. P. (Côte d'Ivoire) in Feb (Lim & Van Coeverden de Groot 1997), and one ♀ was pregnant in Nov on Mt Nimba (Coe 1975).

Conservation IUCN Category: Least Concern.

GENUS *Desmomys*

Scrub Rats

Desmomys Thomas, 1910. Ann. Mag. Nat. Hist., ser. 8, 5: 284. Type species: *Pelomys harringtoni* Thomas, 1902.

Desmomys harringtoni.

The genus contains two species endemic to Ethiopia. Usually placed as a subgenus of *Pelomys* (e.g. Ellerman 1941, Misonne 1974) but cranial and body measurements are outside the normal range associated with *Pelomys* (Musser & Carleton 2005). The main diagnostic characters of the skull are a slight longitudinal ridge on outer surface of each upper incisor, ridge-like cusp t9 connecting central cusp t8 with labial cusp t6 on M¹ and M², ridge-like cusp t7 on M², well developed zygomatic plate, dome-shaped braincase, and heavily build mandibles (Figure 65). Semi-arboreal habit. The genus resembles *Myiomys* and *Pelomys* and is placed in the same lineage (based on mitochondrial DNA sequences) as *Arvicanthis*, *Lemniscomys*, *Rhabdomys*, *Pelomys*, *Myiomys* and *Arvicanthis* (Ducroz *et al.* 2001); and

Figure 65. Skull and mandible of *Desmomys harringtoni* (BMNH 69.11.4.102 [skull], BMNH 70.752 [mandible]).

is more closely linked with *Rhabdomys* than with the other genera (see Musser & Carleton 2005). The species are distinguished by size, karyology and geographic distribution.

D. C. D Happold

Desmomys harringtoni HARRINGTON'S SCRUB RAT (HARRINGTON'S DESMOMYS)

Fr. Rat de Harrington; Ger. Harringtons Buschratte

Desmomys harringtoni (Thomas, 1902). Proc. Zool. Soc. Lond. 1902: 313. Katchisa, Shoa Province, Ethiopia. 2800 m.

Taxonomy Originally described in the genus *Pelomys*. The taxonomic name for this species has had a confused history (Dieterlen 1974, Yalden & Largen 1992). Although formerly placed in the genus *Pelomys* (e.g. Yalden *et al.* 1976), *harringtoni* is separated from *Pelomys* and allocated to the genus *Desmomys* (Musser & Carleton 1993, 2005, Yalden *et al.* 1996) on the basis of its distinctive tooth morphology (see Genus profile). The form *rex* (given as *Pelomys rex* in Yalden *et al.* 1976) is now considered as a synonym of *Myiomys dybowskii*. Synonyms: none. Chromosome number: 2n = 52; aFN = 72 (Capanna *et al.* 1996; see also *D. yaldeni*).

Description Medium-sized rodent, superficially similar to *Arvicanthis*. Pelage long (10–15 mm) and soft. Dorsal pelage blackish-brown, especially on mid-dorsal line; hairs dark grey at base, buff or yellowish at tip; some hairs longer, pure black; agouti pattern. Flanks paler, buff to pale cinnamon. Ventral pelage pure white or greyish-white, clearly delineated from colour of flanks by thin buff band; thin buff mid-ventral stripe on chest. Head similar in colour to dorsal pelage. Ears rounded, pigmented, with short buff hairs. Chin and throat greyish-white. Forelimbs with four digits; Digit 1 absent, Digit 5 reduced. Hindlimbs with five digits; Digits 1 and 5 reduced.

Tail long (ca. 95% of HB), bicoloured, dark above, pale below, ringed with scales, and short bristles. Skull: faint longitudinal ridge on each upper incisor; cheekteeth (M^1 – M^3) 6.2 (5.8–6.5) mm; width of palate (M^1 – M^1) 5.9–6.7 mm; and width of M^1 1.91–2.04 mm. Nipples: not known.

Geographic Variation None recorded.

Similar Species

D. yaldeni. Similar in appearance; on average HB slightly smaller; tail longer and relatively longer (ca. 115% of HB); on average shorter M^1 – M^3 (5.9–6.0 mm), narrower M^1 : (1.69–1.83 mm) and narrower palate (M^1 – M^1 : 5.2–5.4 mm); distribution very restricted.

Pelomys fallax. Groove on outer surface of each upper incisor; four functional digits on forefoot; widespread distribution.

Arvicanthis spp. No groove or ridge on outer surface of each upper incisor; four functional digits on forefoot; very widespread distribution.

Myiomys dybowskii. Groove on outer surface of each upper incisor; three functional toes on forefoot; widespread distribution.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Widespread on the Ethiopian plateaux, primarily on the western side of the Ethiopian Rift Valley at altitudes between 1800 and 2800 m. In Menagesha State Forest, occurs at altitudes of 2200–3400 m (Afework Bekele 1996a).

Habitat ‘Bushy habitats’, disturbed open forest with *Kalanchoe* vegetation, amongst boulders and stony crevices in *Erica* scrub at higher altitudes, and marshes in W Ethiopia (Afework Bekele 1996a, Rupp 1980). Out of 45 specimens collected in Menagesha State Forest, three were in ‘bush’, eight in the open forest and 34 in the *Erica* scrub where boulders are common.

Abundance In bush habitats at Menagesha State Forest comprised 15.4% ($n = 293$; 9 spp.) of small rodents captured, and was the second most common species after *Myomys albipes*; in contrast, comprised only 2% of rodents captured in Juniper forest (Afework Bekele 1996a). In three suitable habitats in W Ethiopia formed 11–23% of rodents and was usually one of the most numerous rodent species (Rupp 1980). Generally a common species in suitable habitats.

Remarks Mostly nocturnal. Semi-arboreal and therefore unlikely to compete with the closely related terrestrial *Arvicanthis* where the two species are syntopic. Nests of woven grass built in bushes (label, BMNH). Six young in nest found in Dec (label, BMNH).

Desmomys harringtoni

Conservation IUCN Category: Least Concern.

Desmomys yaldeni YALDEN'S SCRUB RAT (YALDEN'S DESMOMYS)

Fr. Rat de Yalden; Ger. Yaldens Buschratte

Desmomys yaldeni Lavrenchenko, 2003. Bonn. Zool. Beitr. 50: 320. Sheko Forest, Illubabor, Ethiopia. 1930 m.

Taxonomy With the exclusion of *Desmomys rex* (transferred by Musser & Carleton [1993] to *Myiomys*), *Desmomys* became a monotypic genus endemic to Ethiopia until Lavrenchenko (2003) reported the occurrence of this new species. *Desmomys yaldeni* is distinguished by its slightly smaller mean size, dark feet (ginger dorsally in *D.*

harringtoni), rather longer tail, more slight dentition and distinctive karyotype. Synonyms: none. Chromosome number: $2n = 52$, as in *D. harringtoni*, but with fewer bi-armed pairs (7 pairs, incl. sex chromosomes) and more acrocentric chromosomes (19 pairs) (cf. 12–13 bi-armed pairs and 13 acrocentrics in *D. harringtoni*).

*Desmomys yaldeni*

Description Slight, harsh-furred rat, very similar to *D. harringtoni* in appearance. Hairs ca. 11 mm. Dorsal pelage sandy-brown agouti dorsally; hairs grey at base with rufous subterminal band and black tip, giving the speckled (agouti) pattern. Ventral pelage greyish-white; grey at base, white at tip. Mid-ventral longitudinal straw-coloured band. Ears blackish, inner surfaces with short rufous hairs. Dorsal surface of forefeet blackish-rufous, fingers black, claws black. Hindfeet black dorsally. Tail very long (ca. 115% of HB), black above, yellow below, but hairs short so not producing a bicoloured tail (cf. *D. harringtoni*). Skull on average smaller than in *D. harringtoni*, though overlapping in most measurements. M^1 – M^3 (5.9–6.00 mm), breadth of M^1 (1.69–1.83 mm) and breadth across palate (M^1 – M^1 : 5.2–5.4 mm) significantly and distinctively smaller than for *D. harringtoni*. Nipples: not known.

Geographic Variation None recorded.

Similar Species

D. harringtoni. Similar in appearance; tail shorter and relatively shorter (ca. 95% of HB); on average longer M^1 – M^3 (6.0–7.0 mm), wider M^1 (1.91–2.04 mm) and wider palate (M^1 – M^1 : 5.9–6.7 mm); distribution more widespread.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Only known from Illubabor Province, SW Ethiopia at 1800–1930 m.

Habitat Moist evergreen montane forest with abundant parasitic *Ficus* and an understorey of *Coffea arabica*. Syntopic species at type locality are *Dendromys melanotis*, *Lophuromys chrysopus*, *L. ?sikapus*, *Myomys albipes*, *Mus mahomet*, *Lemniscomys macculus* and *Otomys* sp. (Lavrenchenko 2003).

Abundance Only known from three specimens.

Remarks Longer tail suggests that this species is more arboreal than *D. harringtoni*, and shorter toothrow suggests the diet may be invertebrates and berries/fruits (Lavrenchenko 2003).

Conservation IUCN Category: Endangered.

Geographic range is limited and forest clearance is reducing the extent of suitable habitat.

GENUS *Grammomys*

Thicket Rats

Grammomys Thomas, 1915. Ann. Mag. Nat. Hist., ser. 8, 16: 150. Type species: *Mus dolichurus* Smuts, 1832.

The genus *Grammomys* contains 11 species (Table 32), and has a wide geographical range in many rainforest and savanna habitats throughout sub-Saharan Africa. Four of these species (*G. cometes*, *G. dolichurus*, *G. ibeanus* and *G. kuru* [formerly *G. rutilans*]) have large geographical ranges; the remainder are rather localized. All species are arboreal or scansorial.

The genus is closely related to *Thamnomys* but is now considered as a valid genus although it shares many similarities with *Thamnomys* (see below). The characters of the genus are medium size, rather short and soft pelage, very long semi-prehensile tail (usually 120–160% of HB)

and relatively small hindfeet. The dorsal pelage is usually grey, brown or rufous without any patterning, and ventral pelage is pure white or cream. The t7 cusp (the postero-internal cusp) of M^1 and M^2 is never large and often reduced to a mere connecting ridge between t4 and t8 (a character which contrasts with that of *Thamnomys*). The ridge is inwardly projecting, giving a rounded shape to M^1 and M^2 on the lingual side. Together with the rounded shape of M^3 , the molars are easily distinguishable from the almost rectangular-shaped molars of *Thamnomys* spp., which have a quite large t7. In most species of *Grammomys*, t9 of M^1 and M^2 is well developed and t3 is mostly vestigial. The central row of

Table 32. Species in the genus *Grammomys*. Arranged in order of increasing mean head and body length.
(n. d. = no data.)

^a One specimen only.

^b Two specimens only.

^c Range of measurements; means not available.

^d Formerly *G. rutilans*.

^e Known only from the holotype specimen.

cusps (t2–t5–t8) is markedly enlarged compared with the relatively smaller cusps of *Thamnomys*. The skull is comparatively short, the braincase appearing broad; supraorbital ridges are relatively weak or even absent, and the auditory bullae are small (Figure 66).

All species in the genus are arboreal, living in habitats where there are grasses, tangles, shrubs and trees for climbing. The long tail and semi-opposable digits of the hindfeet enable quick and efficient movement along small stems and twigs, and along larger branches. Thicket Rats are primarily nocturnal; in the daytime, they rest in nests of stems and leaves that are intertwined among the twigs of shrubs, and some may rest in hollows of trees. All species are vegetarian, feeding on a wide range of plants and fruits. Reproduction (for species that have been studied) is mostly seasonal; litter-sizes are small (usually 1–3 young/litter) compared with other rodents of

RIGHT: Figure 66. Skull and mandible of *Grammomys kuru* (HC 1263).

similar size – a character that may be related to continuous nipple-dragging by the mother, even when climbing and active outside the nest at night.

The genus *Grammomys* was split from *Thamnomys* by Thomas (1915) to accommodate those species in which t_7 on M^1 and M^2 was absent or reduced. Prior to Ellerman (1941), who accepted this arrangement, most studies referred to *Grammomys* as a subgenus of *Thamnomys* (see Rosevear 1969 for an historical review). In Ellerman's view, the major differences in cuspidation, and in the form of the feet, were

sufficiently important to warrant generic status to *Grammomys*, a view that is now widely accepted. The genus *Thamnomys* is now confined to three species (see that profile).

Eleven species are recognized here, although one species, *G. kuru* (= *G. rutilans*) may be a complex of two species. Species of the genus are distinguished by size, colour of pelage, size and details of skull characters and chromosome number.

Fritz Dieterlen

Grammomys aridulus JEBEL MARRA THICKET RAT (ARID WOODLAND GRAMMOMYS)

Fr. Souris sylvestre de Jebel Marra; Ger. Jebel Marra Buschmaus

Grammomys aridulus Thomas and Hinton, 1923. Proc. Zool. Soc. Lond. 1923: 268. Kulme, Wadi Aribo, Darfur, Sudan. 3300 ft (1005 m).

Taxonomy Originally described as 'a very well-marked species', later treated as a subspecies of *Grammomys macmillani* (Allen 1939, Ellerman 1941, Setzer 1956, Happold 1966b) or included in *Grammomys dolichurus* (Misonne 1974). Considered to be a valid species by Hutterer & Dieterlen (1984). Synonyms: none. Chromosome number: not known.

Description Small-sized *Grammomys*. Dorsal pelage pallid, reddish-brown to dull olive-brown, darker on mid-dorsal line. Flanks, rump and base of tail bright tawny. Ventral pelage creamy-white, contrasting with colour of flanks. Top of head and neck dull brownish-grey; cheeks grey. Ears bright ochraceous-tawny on outer and inner surfaces; small white patch at base of ears. Vibrissae very long, up to 39–47 mm. Fore- and hindlimbs and feet creamy-buff. Tail extremely long (ca. 163% of HB), darker above, paler below; terminal third with hairs, small brown pencil at tip. In juveniles, dorsal pelage dull brownish on rump, greyish on head. Nipples: 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species The only species of *Grammomys* in its area of distribution. Species of *Grammomys* of similar size are:

G. dolichurus. Tail shorter and relatively shorter (mean 166 mm, ca. 150% of HB); dorsal pelage gingery-brown to cinnamon-brown; widespread in eastern Africa.

G. kuru. Tail of similar length and relative length; dorsal pelage greyish-brown; widespread in western Africa.

Distribution Endemic to Africa. Sahel Savanna BZ / Afroalpine BZ. Recorded only on Jebel Marra, Sudan, and probably endemic to the jebel. Recorded from four localities (Kulme, Gollol, Mortagello and Kelling) on the western side of the jebel at 1000–2000 m where annual rainfall is 800–1000 mm. Not recorded from drier semi-arid lowlands surrounding the jebel. This species has the northernmost geographic range of any species in the genus.

Habitat Trees, bushes, hedges in valleys. May occur close to human habitations. Vegetation in preferred habitat at 4000–6000 ft includes *Cordia abyssinica*, *Ficus* spp., *Euphorbia candelabrum*, *Hyparrhenia pseudocimbaria* and *Andropogon* spp. (Happold 1966b).

Abundance Rare. Known only from the type and a few specimens collected in 1965 (Happold 1966b) and 1983 (Dieterlen & Nikolaus 1985).

Remarks Arboreal, probably with similar adaptations to other species in the genus. One pregnant ♀ and two lactating ♀♀ in Jul (Dieterlen & Nikolaus 1985), and one subadult in Nov (Happold 1966b) suggest reproduction during wet season (May–Sep; 60% of annual rainfall in Jul–Aug; Wickens 1976). Embryo number: 1 (n = 1); litter-size: 4 (one ♀ with young, 3–4 weeks old).

Conservation IUCN Category: Data Deficient.

The very small area of distribution and rarity of the species are cause for concern.

Grammomys buntingi BUNTING'S THICKET RAT (BUNTING'S GRAMMOMYS)

Fr. Souris sylvestre de Bunting; Ger. Buntings Buschmaus

Grammomys buntingi (Thomas, 1911). Ann. Mag. Nat. Hist., ser. 8, 7: 381. Gonyon, Basso, Liberia.

Taxonomy Originally described in the genus *Thamnomys*. Misonne (1974) included *buntingi* within *G. dolichurus* although other authors have regarded it as a valid species (e.g. Rosevear 1969, Petter & Tranier 1975, Musser & Carleton 1993, 2005). Synonyms: none. Chromosome number: 2n = 52, FN = 66 (Petter & Tranier 1975).

Description Small arboreal rat with extremely long tail. Dorsal pelage olive-grey to sandy-brown, becoming reddish-brown on rump; hairs dark grey at base, reddish-brown at tip. Flanks grey. Ventral pelage pure white. Colour of dorsal pelage delineated from ventral pelage by thin line of cream or buff. Ears comparatively small. Fore- and hindlimbs buffy-brown. Tail very long (ca. 157% of HB). Skull with t7 of M¹ poorly developed or absent. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Grammomys kuru. On average larger in all body measurements; skull slightly larger and M¹–M³ longer (5.1–5.3 mm); chromosome number: 2n = 36; may be sympatric or parapatric in Côte d'Ivoire.

Distribution Endemic to Africa. Rainforest BZ (Western Region) and adjacent Northern Rainforest–Savanna Mosaic. Recorded from Sierra Leone, Liberia, Guinea and Côte d'Ivoire. Not recorded from Ghana or Gambia (Grubb *et al.* 1998).

Habitat Probably similar to *G. kuru* – secondary tangles on edge of rainforest (and gallery forests in Rainforest–Savanna Mosaic).

Abundance Uncertain, but probably 'rather rare' (Rosevear 1969). Only one individual was found at Foro-Foro, Côte d'Ivoire, in moist Guinea savanna (= 0.03% of all small rodents, n = 3906; Gautun 1975).

Remarks Very little is known about this species, but its biology is likely to be similar to *G. kuru* (= *G. rutilans*). The diet consists of seeds and leaves (T. S. Jones in Grubb *et al.* 1998).

Conservation IUCN Category: Data Deficient.

***Grammomys caniceps* GREY-HEADED THICKET RAT (GREY-HEADED GRAMMOMYS)**

Fr. Souris sylvestre du Kenya; Ger. Graukopf-Buschmaus

Grammomys caniceps Hutterer and Dieterlen, 1984. Stuttgarter Beitr. Naturk., ser. A, 374: 12. Malindi, Kenya.

Taxonomy Roche *et al.* (1984) referred to specimens of this species from Somalia as *G. dolichurus*. Synonyms: none. Chromosome number: $2n = 56$, $FN = 78$ (Hutterer & Dieterlen 1984; see also below).

Description Small climbing rat with very long tail. Dorsal pelage grey streaked with cinnamon-brown turning to bright cinnamon on rump; hairs mid-grey on basal two-thirds, bright cinnamon on terminal third. Scattered pure black hairs give blackish flecked appearance on back. Flanks paler with fewer black hairs. Ventral pelage pure white, clearly delineated from colour of flanks. Head similar in colour to dorsal pelage. Dark bar running from eye to base of whiskers. Upper lips, lower part of cheeks, chin and throat pure white. Comparatively short (30–34 mm) black vibrissae. Ears large, conspicuous, covered with short pale brown or pale cinnamon hairs. White postauricular spot extending dorsally onto back of head. Forelimbs white, short, with four well-developed digits (Digit 1 reduced to small tubercle without claw). Hindlimbs relatively short, white, with five digits. Tail very long (ca. 150% of HB), brown, scaly, appears almost naked but covered with very short brown bristles; white hairs at terminal end form small inconspicuous pencil. Nipples: $2 + 1 = 6$, or $1 + 1 = 4$.

Geographic Variation Roche *et al.* (1984) analysed the chromosomes of five specimens from Somalia and found a high degree of variation ($2n = 54$ to 61).

Similar Species

G. macmillani. On average larger in body and cranial measurements; dorsal pelage less grey.

G. cometes. On average larger in body and cranial measurements; different geographical distribution.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Known only from Malindi, Kenya, and southern Somalia (Afgoi and Mogadiscio; Roche *et al.* 1984).

Habitat Probably dry coastal savanna. The holotype was found on a palm tree in a tourist area at Malindi. Roche *et al.* (1984) found animals in a nest on an *Acacia* tree.

Abundance No information. Appears to be uncommon.

Remarks Scansorial with a prehensile tail. Captive animals showed well-developed climbing behaviour. They were able to hang upside-down holding on with the hindfeet and curling the tail around a twig. Diet in the wild is unknown, but captive animals fed on seeds,

*Grammomys caniceps*

fruit and insect larvae. Bowl-like nests are constructed in *Acacia* trees (Roche *et al.* 1984). Captive-bred animals were tolerant towards other conspecifics and lived in groups of 5–10 animals in a single large cage; under these conditions they reproduced provided sufficient nest boxes and branches were provided (R. Hutterer unpubl.).

Conservation IUCN Category: Data Deficient.

R. Hutterer

Grammomys cometes MOZAMBIQUE THICKET RAT (MOZAMBIQUE GRAMMOMYS)

Fr. Rat sylvestre de Mozambique; Ger. Mosambik-Buschmaus

Grammomys cometes Thomas & Wroughton, 1908. Proc. Zool. Soc. Lond. 1908: 549. Inhambane, Mozambique.

Taxonomy The taxonomic and geographic limits of this species are uncertain because of the morphological similarity between *G. cometes* and *G. ibeanus*. Misonne (1974) included *ibeanus* as a subspecies of *G. cometes*, as did Hutterer & Dieterlen (1984), with a geographic range from South Africa to S Sudan. Musser & Carleton (1993, 2005) restrict *G. cometes* to south of the Zambezi R., and consider all populations north of the river to be *G. ibeanus* (see that profile). The northern populations, between the Zambezi R. and Sudan, show considerable morphological variability and referring them all to *G. ibeanus* remains questionable (F. Dieterlen unpubl.). The form *silindensis* from S Zimbabwe, considered as a subspecies of *G. cometes* (e.g. Smithers 1983) is now considered a synonym. Synonyms: *silindensis*. Subspecies: none. Chromosome number: not known.

Description Small to medium-sized climbing rat with very long tail; the largest species (with *G. ibeanus*) in the genus. Pelage short and silky. Dorsal pelage reddish-brown to buff; hairs dark slate-grey on basal two-thirds, buff on terminal one-third; some hairs pure black. Ventral pelage pure white, clearly delineated from colour on flanks. Head similar in colour to dorsal pelage. Postauricular patch usually present. Fore- and hindfeet short, white; claws short. Tail very long (120–160% of HB), with a distinct terminal pencil. Skull: greatest length >31 mm; M¹–M³ long (4.5 mm); anterior palatal foramina long, extending posteriorly to level with t3 of M¹. Nipples: 0 + 2 = 4 or 1 + 2 = 6.

Geographic Variation None recorded.

*Grammomys cometes***Similar Species**

G. dolichurus. On average smaller; white postauricular patch absent; skull length <31 mm; easily confused with *G. cometes* in KwaZulu–Natal, South Africa.

G. ibeanus. Similar in size, north of the Zambezi R. only.

Distribution Endemic to Africa. South-eastern part of Zambezi Woodland BZ, and Coastal Forest Mosaic BZ of southern Africa. Recorded from Pirie Forest in Eastern Cape Province of South Africa north through KwaZulu–Natal and (former) Transvaal Provinces to E Zimbabwe and Mozambique south of the Zambezi R. (Musser & Carleton 1993). Following Musser & Carleton (1993, 2005), specimens from Malawi (De Graaff 1981, Ansell & Dowsett 1988) and further north formerly ascribed to this species are considered to be *G. ibeanus*.

Habitat Dense evergreen forests in South Africa (De Graaff 1981). In KwaZulu–Natal, found in mature *Podocarpus* forests and in montane forests; prefers denser, more well-developed forest than *G. dolichurus* (Taylor 1998). Recorded from forest fringes and thickets in Mozambique (Smithers & Lobão Tello 1976).

Abundance Uncertain, but appears to be rare or uncommon in collections. Much less common than sympatric *G. dolichurus*.

Remarks Arboreal and nocturnal. Probably similar to other species in the genus. Embryo number: 3 (n = 1; Ngome Forest, KwaZulu–Natal, South Africa; Taylor 1998).

Conservation IUCN Category: Least Concern.

Status recorded as 'Indeterminate' in South Africa (Smithers 1986b), and as 'Vulnerable' because of its dependence on evergreen forests (Schlitter 1989).

Grammomys dolichurus WOODLAND THICKET RAT (COMMON GRAMMOMYS)

Fr. Souris sylvestre commune; Ger. Wald-Buschmaus

Grammomys dolichurus (Smuts, 1832). Enumer. Mamm. Capensium, p. 28. Near Cape Town, South Africa.

Taxonomy Originally described in the genus *Mus*, but more recently allocated to *Thamnomys* (e.g. Hanney 1965; Smithers 1983) or *Grammomys* (e.g. Hutterer & Dieterlen 1984, Musser & Carlton 1993, Taylor 1998). Many names (including *surdaster*) are now synonyms; individuals in the north of the geographic range may be a separate species *G. surdaster* (Musser & Carlton 1993). Synonyms: *angolensis*, *arborarius*, *baliolus*, *discolor*, *elgonis*, *insignis*, *littoralis*, *polionops*, *surdaster*, *tongensis*. Subspecies: none. Chromosome number $2n = 52$, $FN = 66$ (Petter & Tranier 1975).

Description Small arboreal mouse, with dull gingery-brown dorsal pelage and an extremely long tufted tail. Dorsal pelage gingery-brown or cinnamon-brown suffused with grey and black. Dorsal hairs dark grey at base, gingery-brown on terminal third, often with back tip. Guard hairs, grey tipped with black. Ventral pelage usually pure white, clearly delineated from dorsal pelage, often with thin band of pale orange between dorsal and ventral pelage. Head gingery-brown; ears short and rounded, covered with short ginger hairs. Lacks postauricular white ear patch (cf. *G. cometes*). Chin and throat white. Feet white. Digit 1 of forefoot reduced to stump without claw. Hindfeet relatively short, Digit 5 long, adapted for grasping small twigs. Tail extremely long (ca. 150–180% HB), scaly, with short brown or black bristles; long black hairs form terminal pencil at tip. Nipples: $1 + 2 = 6$; $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species

G. cometes and *G. ibeanus*. On average larger; white subauricular patch.

G. macmillani. Usually slightly smaller; dorsal pelage olive-brown or reddish-brown; chromosome number: $2n = 68-76$.

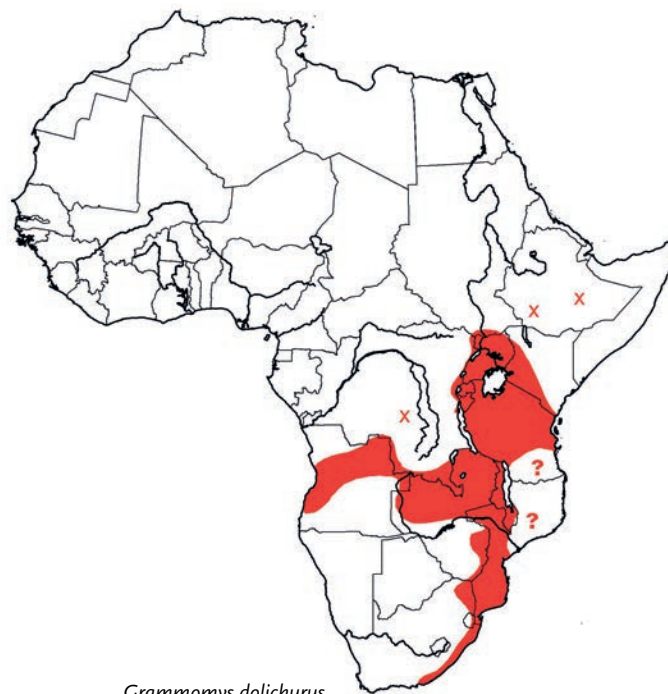

G. kuru. Rainforest BZ; similar in size but tail usually relatively longer; allopatric.

Hylomyscus spp. Smaller (HB: <90 mm, T: <130 mm, WT: <30 g).

Other species of *Grammomys* in eastern Africa (*G. caniceps*, *G. dryas*, *G. gigas*) have restricted ranges.

Distribution Endemic to Africa. Zambezan Woodland BZ, southern part of Somalia–Masai Bushland BZ, marginally in parts of Coastal Forest Mosaic BZ and marginally in lower parts of Afromontane–Afroalpine BZ of South Africa. Recorded from S Sudan through most of eastern Africa to the coastal region of eastern South Africa, and westwards to Angola. Widespread. Outlier populations in southern Ethiopia.

Habitat Woodland savannas and gallery forests within savanna. Recorded in many habitats where climbing is possible, including *Brachystegia* and *Acacia* woodlands, evergreen gallery forests, afromontane forests, shrubs, thickets, tall grasses and reeds.

*Grammomys dolichurus*

Abundance Although probably fairly abundant in suitable arboreal habitats, comprises only a small proportion of small mammals captured on the ground. For example, 0.2% in *Acacia* woodlands and 1.2–6% in plateau grasslands of Malawi (Hanney 1965); 1% in thicket habitats at Lengwe N. P., Malawi (Happold & Happold 1991); 1% in *Pennisetum* grassland and 'grassbush' of E DR Congo (Dieterlen 1967c); 3% in Majanga Forest, Uganda (Delany 1971); and 3.7% in afromontane forests of KwaZulu–Natal, South Africa (Wirminghaus & Perrin 1993). Density of ca. 1.1/ha in afromontane forest of South Africa (Wirminghaus & Perrin 1993).

Adaptations Nocturnal and arboreal; may be terrestrial where trees and bushes are sparse. Very agile, running along twigs and jumping from twig to twig. Adaptations for climbing include long Digit 5 on hindfoot, and extremely long tail for balance. The tail is sometimes wrapped around twigs and small branches but is not fully prehensile. Spherical nests with single entrance made of grasses and leaves, 20–30 cm in diameter, are built up to 4 m above ground, and lined with finely shredded grass. Other nests found in axils of banana leaves and pineapple plants. On occasion, Woodland Thicket Mice have been found in the abandoned nests of birds (barbets and weavers). Rapid development of young, especially early separation of the toes and development of the grasp reflex, are probably adaptations to arboreal life. In afromontane forests of South Africa, body fat varied by a factor of ca. 2.5 during the year (lowest in winter –18% mean minimum in winter; highest in summer –42% mean maximum). The annual fluctuation is lower than for terrestrial rodents in the same habitat, probably because Woodland Thicket Rats

have access to alternative foods (e.g. perched aerial insects and fruits) during winter (Wirminghaus & Perrin 1993).

Foraging and Food Predominantly vegetarian. Probably forages in trees and on the ground. In South Africa, average diet throughout the year was 47% fruit, 46% leaves and stems and 6% insects ($n = 11$); for most of year, diet was purely vegetarian and insects were consumed only in spring (Aug–Nov) (Wirminghaus & Perrin 1992). In Malawi (Hanney 1965), Woodland Thicket Mice are purely vegetarian with a preference for fruit and green bark. Captive individuals fed on cereals and fruit, but would not accept insects.

Social and Reproductive Behaviour Communal, several being found in a single nest. One record stated that they may be 'found in family parties, sometimes several families together' (Sweeney 1970, in Ansell & Dowsett 1988).

Reproduction and Population Structure Reproductive activity varies by locality and climate. In Malawi, pregnant or lactating ♀♀ in Feb, Mar and May (wet season) (Hanney 1965), and in Zimbabwe, pregnant ♀♀ in Jan and Sep (Smithers & Wilson 1979). In South Africa, ♀♀ in reproductive condition mainly in summer and autumn (Dec, Jan, Mar, May, Jul), and young in summer and autumn (Mar–Jul) (Wirminghaus & Perrin 1993). In Uganda, ♀♀ may give birth to young every 5–6 weeks (Delany 1975), suggesting more-or-less continuous reproduction in the tropics and smaller numbers of young/litter. Gestation ca. 24 days. Embryo number: 4.6 (3–6; Malawi; Hanney 1965); 2.8 (1–3; Uganda; Delany 1975). Young precocial at birth, covered with fine greyish hairs. Mean

weight at birth: 4.2 g. Mother nipple-drags young. Eyes open and young climb at Day 15. Growth and development rapid (Bland 1973; Panagis & Nel 1981). Adult size attained at ca. Day 40. Reproductive maturity attained when weight ca. 30 g and HB ca. 80–90 mm (Dieterlen 1967c).

Predators, Parasites and Diseases Domestic cats may prey on these mice in urban areas (e.g. Durban; Taylor 1998). Ectoparasites include 14 species of fleas, four species of mites and two species of ticks (details in De Graaff 1981).

Conservation IUCN Category: Least Concern.

Grammomys dryas ALBERTINE RIFT THICKET RAT (ALBERTINE RIFT GRAMMOMYS)

Fr. Souris sylvestre du Rwenzori; Ger. Dryas-Buschmaus

Grammomys dryas (Thomas, 1907). Ann. Mag. Nat. Hist., ser. 7, 19: 123. Mubuku Valley, E Rwenzori, Uganda. 6000–7000 ft (1830–2130 m).

Taxonomy Originally described in the genus *Thamnomys*, an arrangement modified by Allen (1939) to *Thamnomys* (*Grammomys*) *dryas*. Placed in the genus *Grammomys* by Ellerman (1941), and as a synonym of *Grammomys dolichurus* by Misonne (1963, 1974) and Delany (1975). Referred to as *Thamnomys surdaster dryas* by Rahm & Christiaensen (1963), as *Thamnomys dolichurus dryas* by Rahm (1967), and as *Thamnomys surdaster* by Dieterlen (1967a, c). Maintained as a valid species by Musser & Carleton (1993, 2005). Synonyms: none. Chromosome number: not known.

Description Small to medium-sized rat, with very long tail (ca. 160% HB). Dorsal pelage tawny-brown, richer ochraceous on rump; head grey to greyish-brown. Flanks paler. Ventral pelage pure white. Colour of flanks and ventral pelage separated by thin line of buff. Upper surface of fore- and hindlimbs pale buff. Tail uniformly dark brown, with pencil at tip. Skull lightly built with delicate molars; auditory bullae small; anterior palatal foramina reaching to the level of the front of M^1 . Postero-internal cusp of first and second molars reduced to a narrow connecting ridge, often hardly perceptible. Nipples: $0 + 2 = 4$.

Geographic Variation Specimens from the type locality (Rwenzori Mts) are a brighter ochraceous colour compared with those from Kahuzi–Biega N. P. (DR Congo) and Kibira N. P. (Burundi). In Bwindi Impenetrable N. P., Uganda, two 'forms' may be recognized: (a) a higher elevation form (<2000 m), referred to here as *G. dryas*, with broader zygomatic plate, more inflated auditory bullae, and longer and higher skull; and (b) a mid-elevation form (1500–1700 m) that may represent a distinct taxon.

Similar Species In allied sympatric montane *Thamnomys* (i.e. *T. kempfi*, *T. venustus*), postero-internal cusp is well-developed, and M^1 – M^3 is >6 mm (cf. <5 mm in *Grammomys*). Ventral pelage of *Thamnomys* is grey at base.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Endemic to the Albertine Rift Valley and surrounding hills of Uganda, Burundi, Rwanda and E DR Congo (including Idjwi I. in L. Kivu).

Habitat Exhibits a wide range of habitat preferences. In the L. Kivu region, prefers woodland savanna, banana plantations and sometimes shrubs and hedges around villages (Rahm 1967). Commonest in

*Grammomys dryas*

secondary growth with shrubs adjacent to swamps and in herbaceous savanna (at Tshiziri near L. Kivu, 1500 m). Not recorded in rainforest habitats where replaced by *G. rutilans* (now *G. kuru*) and *Thamnomys kemp* (Rahm 1967). Occurs in forested habitats as well as secondary growth in Kibira N. P. (Burundi, 1880–2390 m) and Bwindi Impenetrable N. P. (Uganda). In Mgahinga Gorilla N. P. (2700 m) prefers recolonizing shrubby habitats in *Hagenia* forest. Recorded at elevations between 1030 m (FMNH, Misonne 1963, Rahm 1967) and 2300 m (FMNH).

Abundance Abundance varies according to habitat and locality. Comprised 2.9% of small mammals (rodents and insectivores) and 2.4% of small rodents at five localities near L. Kivu, DR Congo (Rahm 1967), and was the 8th most common rodent species of 26 species captured ($n = 2340$ small mammals). Percentage abundance varied from 0% ($n = 300$ rodents) to 13% (3rd most abundant rodent; $n = 355$). In *Pennisetum* grasslands near L. Kivu, and in 'grass-bush habitats', formed 1% (and the least abundant) of all small

rodents (Dieterlen 1967a). In other locations, comprised 6% in Mgahinga Gorilla N. P., Uganda; 1% (mesic habitats, 500–1540 m) and 5.5% (forest habitats, 1500–2350 m) in Bwindi Impenetrable N. P., Uganda; and <1% (1220 m), 7% (2300 m) and 12% (2130 m) in Rwenzori Mts (DR Congo) (FMNH).

Remarks Nocturnal and arboreal, but often caught on ground. Vegetarian; stomach contents contained vegetable material and ground nuts (Rahm & Christiaensen 1966). Nests constructed of grasses and herbs found among shrubs and thickets (Rahm 1967). No well-defined breeding season; pregnancies recorded in Feb, Mar, Jul and Nov throughout geographic range. In Feb, one pregnant ♀ of one adult ♀ sampled (Bwindi Impenetrable N. P., Uganda); in Mar, one of two (Kibira N. P., Burundi), one of one (Bwindi Impenetrable N. P., Uganda) and none of three adult ♀♀ sampled (Mgahinga Gorilla N. P., Uganda). In Jul, six of 17 adult ♀♀ sampled (Lwiro, E DR Congo); and in Nov, one of one adult ♀ sampled (Kigezi G. R., Uganda). In Aug, two ♀♀ sampled in Kibira N. P., Rwanda, were not pregnant. No data for other months. Embryo number: 2.8 (1–3, mode 3, $n = 10$; Dieterlen 1967a, Rahm 1967, FMNH).

Conservation IUCN Category: Near Threatened.

Grammomys gigas GIANT THICKET RAT (MOUNT KENYA GRAMMOMYS)

Fr. Souris sylvestre du Mont Kenya; Ger. Grosse Buschmaus

Grammomys gigas Dollman, 1911. Ann. Mag. Nat. Hist., ser. 8, 7: 527. Solai, Mt Kenya, Kenya. 9000 ft (2740 m).

Taxonomy Known only by the holotype, an old ♂ with very worn molars. Recognized as a valid species by several authorities (Allen 1939, Ellerman 1941, Hutterer & Dieterlen 1984, Musser & Carleton 1993, 2005). Hollister (1919), without personal knowledge of the holotype, designated it as a synonym of *G. cometes*. The distinctly larger body and skull measurements suggest that *gigas* should be recognized as a separate species; however, it may be that it is simply a large individual of *G. ibleanus* (Musser & Carleton 2005). The external measurements of *G. gigas* are within the range recorded for *G. ibleanus*,

although the skull and teeth measurements are larger. Synonyms: none. Chromosome number: not known.

Description Medium-sized climbing mouse with very long tail; the largest species (with *G. ibleanus* and *G. cometes*) in the genus. Dorsal pelage 'olive-grey washed with tawny buff, the reddish tint increasing posteriorly on the rump becoming bright orange-red. Head, sides of face, neck and shoulders washed with yellowish buff. Flanks richly tinted with orange-buff and sharply marked off from

the white underparts' (Dollman 1911c). Ventral pelage white tinted with very pale pinkish-buff, the general colour appearing as almost white. Upper surfaces of fore- and hindfeet buff. Tail very long (ca. 152% of HB), covered with short hairs and with longer hairs forming slight pencil at tip. Skull very large and massive. Braincase much larger than in the allied species. Zygoma stout and heavy. Anterior palatal foramina very long. Auditory bullae large and slightly inflated. Molar teeth exceptionally large, the toothrow longer and broader than in *G. ibeanus* (Dollman 1911c). Nipples: not known.

Geographic Variation None recorded.

Similar Species (size comparisons refer to mean values only)

Grammomys ibeanus. Slightly smaller (see also above); sympatric.

G. cometes. Slightly smaller; south of Zambezi R. only.

G. dolichurus. Smaller; commoner; larger geographic range.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known only from the type locality on Mt Kenya. Dollmann (1911c) mentioned a further specimen from Kasituka, west of Mt Kenya.

Habitat No information; presumably similar to *G. ibeanus*.

Abundance Only known by the holotype collected in 1911.

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

Grammomys ibeanus EAST AFRICAN THICKET RAT (EAST AFRICAN GRAMMOMYS)

Fr. Souris sylvestre d'Afrique Est; Ger. Ost Afrikanische Buschmaus

Grammomys ibeanus Osgood, 1910. Field Mus. Nat. Hist. Publ., Zool., ser. 10, 8. Molo, Kenya.

Taxonomy The populations of the *cometes*–*ibeanus* complex north of the Zambezi R. are considered to belong to *G. ibeanus* (following Musser & Carleton 1993, 2004). Considerable variation in morphological variation may indicate that *G. ibeanus*, as understood here, may contain more than one species, but it appears to be a different species from *G. cometes*. The form *insignis* from Mt Elgon, placed as a synonym of *G. dolichurus* by Musser & Carleton (1993), belongs to the *ibeanus*-complex (F. Dieterlen unpubl.). Morphological and distributional limits of *G. ibeanus* are unsatisfactory, particularly the extent of its distribution in Tanzania (Musser & Carleton 2005). Synonyms: *lutosus*, *insignis*. Subspecies: none. Chromosome number: not known.

Description Medium-sized climbing mouse with very long tail; the largest species (with *G. cometes* and *G. gigas*) in the genus. Dorsal pelage rather long and soft, dull olive-brown; hairs dark slate-grey, terminal one-third reddish-brown to dull olive-brown (see also

Geographical Variation). Flanks brownish-grey. Ventral pelage white or cream. Colour of dorsal pelage clearly delineated from ventral pelage, often by thin line of yellow. Ears comparatively large. White postauricular patch absent or present. Fore- and hindfeet with yellowish-red hairs; toes sometimes with silvery hairs. Tail very long (ca. 150% of HB), covered with short hairs and with longer hairs (up to 10 mm) forming slight pencil at tip. Nipples: 1 + 2 = 6.

Geographic Variation In most populations, dorsal pelage is dull olive-brown; in the form *insignis* from Mt Elgon, dorsal pelage is bright tawny-brown and flanks are buffy.

Similar Species (size comparisons refer to mean values only)

G. dolichurus. Smaller HB and T; M¹–M³ shorter (with no overlap in measurements); no postauricular patch; north of the Zambezi R.

G. cometes. Smaller HB and T; M¹–M³ shorter; no postauricular patch; south of the Zambezi R.

*Grammomys ibeanus*

Distribution Endemic to Africa. Zambezian Woodland and Somalia–Masai Bushland BZs, mostly at 2000–3000 m. Recorded from scattered localities in Uganda (Mt Elgon), S Sudan (Imatong Mts), Kenya (both sides of the Rift Valley), Tanzania (rim of Ngorongoro crater, region of L. Manyara, W Usambara Mts, and Mt Poroto), NE Zambia and Malawi. All localities are north of the Zambezi R. (cf. *G. cometes*).

Habitat Probably similar to *G. cometes*. Recorded from moist evergreen montane forests and thickets, edge of moist forest (rim of Ngorongoro crater, Tanzania), and dense vegetation with trees and thickets at 1900–2700 m (Imatong Mts, Sudan) (Dieterlen & Nikolaus 1985, F. Dieterlen unpubl.). On Mt Elgon, found in dense montane

forest, and on rock outcrops with bushes in afroalpine grasslands at 3200–3600 m (Clausnitzer & Kityo 2001, as *G. dolichurus*). The lowest altitude on Mt Elgon, Uganda, seems to be 2750 m, and on Laikipia Plateau, Kenya, ca. 1900 m (Dollman 1911d). In Malawi, recorded from montane forest, bracken, thick undergrowth and inside houses (Ansell & Dowsett 1988, as *G. cometes*) and on the Nyika Plateau (Chitaukali *et al.* 2001).

Abundance No information.

Remarks Arboreal and nocturnal. Embryo number: 3 ($n = 2$; Mt Gargues, Kenya; Hollister 1919). In S Sudan, in Apr (wet season), one lactating ♀ contained two embryos (F. Dieterlen unpubl.). In Malawi (as *G. cometes*), litter-size 2.9 (2–5, $n = 6$); reproduction mainly during the wet season from Nov–Apr (Hanney 1965).

Conservation IUCN Category: Least Concern.

Schlitter (1989) classified *G. cometes* (including *ibeanus*) as ‘Vulnerable’ because of its dependence on evergreen forests.

Grammomys kuru SHINING THICKET RAT (EASTERN RAINFOREST GRAMMOMYS)

Fr. Souris sylvestre de forêt tropicale; Ger. Glanzbuschmaus

Grammomys kuru (Thomas and Wroughton, 1907). Ann. Mag. Nat. Hist., ser. 7, 19: 381. Angu, Uele River, Orientale, NE DR Congo.

Taxonomy Originally described in the genus *Thamnomys*. Referred to as *Thamnomys rutilans* (e.g. Rosevear 1969, Genest-Villard 1972, 1980, Happold 1974), or as *Thamnomys (Grammomys) rutilans* (Misonne 1974) in all publications prior to the present time. Currently allocated to the genus *Grammomys* (see Genus profile). The specific name *rutilans* is now known to be occupied by another species (the non-African *Mus rutilans*), and hence the next available specific name for this species is *kuru* (Musser & Carleton 2005). Not easily distinguished from *G. cometes* (Misonne 1974). Species limits uncertain. Musser & Carleton suggest ‘*G. kuru*’, as understood here, comprises two species: *G. poensis* occurring throughout West Africa from Guinea to Equatorial Guinea, Gabon and N Angola, and *G. kuru* occurring in Central African Republic, DR Congo and W Uganda. Status in Central African Republic, Congo and NW DR Congo uncertain.

Synonyms: *centralis*, *poensis*. Subspecies: none. Chromosome number: $2n = 50$ (as *rutilans*, probably refers to *kuru* from Congo; Matthey 1963a). Chromosome number of $2n = 36$ (*rutilans* in Côte d’Ivoire [Tranier & Dosso 1979] probably refers to *poensis* – see Musser & Carleton 2005).

Description Small arboreal rat with extremely long tail. Dorsal pelage greyish-brown often tinged with dark rufous or chestnut on mid-dorsal region; hairs dark grey at base, brown or dark rufous at tip. Black guard hairs sparsely scattered on mid-back. Flanks paler. Ventral pelage pure creamy-white tinged with orange. Colour of dorsal pelage clearly delineated from ventral pelage, with thin line of conspicuous cinnamon-orange, especially on chest. Head similar in colour to dorsal pelage; nasal regions slightly rufous. Black vibrissae.

Ears small, pigmented with short brown hairs. White subauricular patch absent. Forelimbs short, four digits with short claws; Digit 1 reduced to short pad. Hindlimbs short; hindfeet rather broad; five digits, Digit 1 somewhat elongated; Digit 5 elongated and semi-opposable; short claws. Tail extremely long (ca. 160% of HB), dark brown and scaly with short dark bristles; hairs slightly elongated at tip; tail semi-prehensile. Skull: rather elongated, with slight supraorbital ridges, short rostrum, $t7$ on M^1 well developed; upper incisors slightly opisthodont. Nipples: $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species

G. dolichurus. Ventral pelage pure white, white subauricular patch absent; woodland habitats of the southern savannas; may be sympatric in Uganda.

Hylomyscus spp. On average HB usually smaller; smaller hindfeet; often sympatric and syntopic; widespread in tangles and secondary forest.

Distribution Endemic to Africa. Rainforest BZ and forest relicts in Rainforest–Savanna Mosaics. Recorded from SW Guinea (Mt Nimba) and Côte d'Ivoire eastwards to Cameroon and Central African Republic; also from Equatorial Guinea, Gabon, DR Congo, W Uganda and N Angola, Bioko I. Not recorded from Liberia or Sierra Leone, although may occur in these countries.

Habitat Tangled vegetation in forest clearings and along roadsides, and in secondary forest. Also recorded, rarely, from cocoa and mature cocoa plantations (Jeffrey 1975), and in secondary bush surrounding farmlands. In Dzanga-Sangha, Central African Republic, occurred at similar frequencies in unlogged, logged and monodominant *Gilbertiodendron dewevrei* forests, with no captures in streamside habitats (Ray 1996); preferred micro-habitats were characterized by thick understorey vegetation characteristic of disturbed environments, such as treefall gaps.

Abundance Uncertain; mostly uncommon or rare, but abundance varies geographically. Rosevear (1969) recorded that the species is 'rare' at the western edge of the range (e.g. Côte d'Ivoire). Shining Thicket Rats comprised 7.8% of all small rodents obtained by local collectors trapping on and above ground level in a forest–savanna–farmland mosaic near Ibadan, Nigeria ($n = 584$; Happold 1974), and 5% of all rodents captured above ground level in Mayanga Forest, Uganda ($n = 345$; Delany 1971). They comprised only 1% ($n = 1747$ rodents) captured in terrestrial habitats in Dzanga-Sangha, Central African Republic (Ray 1996). The species was not recorded in primary rainforest when trapping was restricted to ground level only in Ghana (Cole 1975) and Nigeria (Happold 1977).

Adaptations Arboreal and nocturnal. Shining Thicket Rats are primarily arboreal, preferring tangled vegetation where twigs and small branches are less than ca. 25 mm in diameter. They are efficient climbers, using their long tail for balance and gripping small twigs and branches with the elongated semi-opposable Digit 5 of the hindfeet. In Uganda, they have been captured at heights up to ca. 3 m above ground (Delany 1971) but may ascend higher where the tangled vegetation is suitable. In Dzanga-Sangha, Central African Republic,

Grammomys kuru

they were more commonly captured at heights of 2 m and 15 m than on the ground (Malcolm & Ray 2000). Shining Thicket Rats descend to ground level to forage for fruits (see below). Nests are situated in dense vegetation, usually 2–3 m above ground level, and are made of shreds of liana, grasses and other vegetation, which is 'woven' into a hollow sphere (Genest-Villard 1972, D. C. D. Happold unpubl.). Shining Thicket Rats spend the day in their nests; at 21:45–22:00h (some five hours after nightfall) they leave the nest. For the rest of the night until ca. 05:00h they alternate between periods of activity outside and periods of inactivity in the nest (Genest-Villard 1972). Frequent returns to the nest may be associated with temperature control because the temperature in the nest is always warmer than that outside. When disturbed in its nest, a Shining Thicket Rat leaves quickly, descends to the ground and hides in a hole, an unusual escape behaviour for an arboreal species.

Foraging and Food Mainly frugivorous. Forages in tangled vegetation and on the ground (even though never, or rarely, captured on the ground). Perches on small branches while holding food with forefeet. At Mbaiki, Central African Republic, the diet in the wet season (as assessed by analysis of stomach contents) comprises 6% flowers and leaves, 0% seeds, 81% vegetable pulp (probably mostly fruits) and 12% insects; equivalent percentages in the dry season are 6%, 12%, 74% and 8% (Genest-Villard 1980). Shining Thicket Rats are the least insectivorous of 17 species of small mammals (except for *Stochomys longicaudatus*) investigated at Mbaiki. In the wild, they have been observed to feed on 19 spp. of fruits, with variations from month to month depending on which species are fruiting, and on the leaves of 27 spp. of small trees and lianas. In captivity, they ate 48 spp. of fruits (out of 52 spp. offered) (Genest-Villard 1980).

Social and Reproductive Behaviour At Mbaiki, Central African Republic, nests were spaced 30–50 m apart, with only one animal (or a mother with young) in each nest, suggesting a home-

range of 700–2000 m². There is some evidence that males may be territorial since they show agonistic behaviour when one male is confronted with another male (Genest-Villard 1972). In Central African Republic, Shining Thicket Rats share their arboreal niche with *Hylomyscus stella*, *Praomys* sp., *Oenomys hypoxanthus* and *Graphiurus* cf. *murinus*, and do not show agonistic behaviour towards individuals of these species.

Females nipple-drag their young for about 14 days after parturition, until a few days after the eyes of the young have opened. The young remain firmly attached to the mother's nipples, even when she is climbing about outside the nest. The incisors of newborn young are bifurcate at the tip enabling the young to attach very securely to the nipple until about Day 14 after birth.

Reproduction and Population Structure In SW Nigeria (Happold 1974), pregnant ♀♀ (n = 6) were recorded in Mar (end of dry season), Sep, Oct and Nov (end of wet season); during these months more adult ♀♀ were non-pregnant than pregnant. Young animals (less than 20 g, n = 9) were recorded from Apr–Sep (wet season). These limited data suggest a rather long period of reproduction throughout the wet season with only a proportion of adult ♀♀ breeding in any one month. Gestation: ca. 24 days. Litter-size: 1–3 (mode 2; Genest-Villard 1972); 2.1 (2–3, n = 7; Happold 1974). At birth, WT: 4–6 g, ears and eyes closed. Incisor teeth erupt and nipple-clinging begins Day 1. Fine hair on body Day 3. Eyes open Day 6–9. Pelage similar in colour to adult Day 14. Adult size ca. Week 13 (Genest-Villard 1972).

Predators, Parasites and Diseases In Dzanga-Sangha, Central African Republic, predators include the Long-nosed Mongoose

Herpestes naso and other small carnivores. Faecal analysis showed that Shining Thicket Rats comprised 6% of the small rodent prey of the mongoose (n = 86 small rodents, 6 spp.). Likewise they formed 6% of the small rodent prey of other small carnivores (n = 251 small rodents, 10 spp.) (Ray 1998). Shining Thicket Rats are hosts to several species of malarial parasites (*Plasmodium berghi*, *P. vinckei*), none of which are pathogenic to the rats or to humans; they have been used as 'model hosts' to study the biology of malarial parasites in general (Killick-Kendrick 1971).

Conservation IUCN Category: Least Concern.

Grammomys macmillani MACMILLAN'S THICKET RAT (MACMILLAN'S GRAMMOMYS)

Fr. Souris Sylvestre de Macmillan; Ger. Macmillans Buschmaus

Grammomys macmillani (Wroughton, 1907). Ann. Mag. Nat. Hist., ser. 7, 20: 504. Wouida, north of L. Rudolf (= L. Turkana), Ethiopia.

Taxonomy Originally described in the genus *Thamnomys*. Most subspecies are now considered to be synonyms, although one (*G. aridulus*) is now recognized as a valid species. *Grammomys macmillani*, as understood here, is on average smaller than *G. dolichurus*; the two species may be confused on external characters but are easily distinguished by different chromosome numbers. Synonyms: *callithrix*, *erythropygus*, *gazellae*, *oblitus*, *ochraceus*, *usambarae*, *vumbaensis*, *vumbensis*. Subspecies: none. Chromosome number: 2n = 68–76 (Petter & Tranier 1975, Civitelli *et al.* 1989).

Description Small arboreal mouse with very long tail; the smallest species of the genus. Dorsal pelage olive-brown or grey, bright rufous-brown on rump. Flanks paler. Small rusty subauricular tufts. Ventral pelage white or creamy-white. Colour of dorsal pelage clearly delineated from colour of flanks, usually by yellow or orange line. Colour of head similar to dorsal pelage. Limbs short. Tail very long (ca. 160% of HB), with short hairs, with slight pencil of longer hairs at tip. Skull: similar to other *Grammomys*, but with shorter greatest length and shorter M¹–M³. Nipples: 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species

G. dolichurus. Similar in size; chromosome number: 2n = 52; partly sympatric.

Distribution Endemic to Africa. Guinea Savanna BZ and Northern Rainforest–Savanna Mosaic, extending southwards into southern regions of Somalia–Masai Bushland BZ. Recorded from S Sudan, Central African Republic, NE DR Congo, S Ethiopia, Kenya, Uganda and Tanzania (Hutterer & Dieterlen 1984). Also recorded from Sierra Leone (Grubb *et al.* 1998, Musser & Carleton 2005) and Liberia (Musser & Carleton 2005; but not by Kuhn 1966). Limits of distribution uncertain. In addition, Musser & Carleton (1993, 2005) include Malawi, Mozambique and E Zimbabwe, a statement pending revision (and not shown on map).

Habitat Forests, riverine forests, edges of forests, swamps with trees, and grasslands with trees and undergrowth. May also be found

*Grammomys macmillani*

in hollow trees, and in roofs of huts and houses. Most habitats in S Sudan have an annual rainfall of ca. 1000 mm.

Abundance No information.

Remarks Little information available. Arboreal and nocturnal. The diet is largely vegetable material.

Conservation IUCN Category: Least Concern.

Grammomys minnae ETHIOPIAN THICKET RAT (ETHIOPIAN GRAMMOMYS)

Fr. Souris sylvestre d’Ethiopie; Ger. Minna-Buschmaus

Grammomys minnae Hutterer and Dieterlen, 1984. Stuttgarter Beitr. Naturk., Série A Biol. 374: 10. Bulcha Forest, S of Dilla, Sidamo Province, Ethiopia. ca. 1800 m.

Taxonomy Olert *et al.* (1978) described, without naming, a single specimen of a rodent from S Ethiopia that seemed somewhat intermediate between *Grammomys dolichurus* and *Thallomys paedulus*. This was subsequently nominated as the type of *G. minnae* in a review of the genus *Grammomys* (Hutterer & Dieterlen 1984). Synonyms: none. Chromosome number: 2n = 32, FN = 64 (Olert *et al.* 1978).

Description Small *Grammomys*, similar in size to *G. dolichurus* and *G. macmillani*. Dorsal pelage uniformly greyish-brown, except for a slight dark mask round the eyes (in adults). Ventral pelage creamy-white. Colour of dorsal pelage clearly delineated from ventral pelage. Hindfeet greyish-white. Tail very long (ca. 157% of HB), sparsely furred, hairs at tip slightly longer than at base forming a slight pencil. Nipples: not known.

Geographic Variation None recorded.

Similar Species

G. macmillani. Similar size; skull has wider interorbital region, shorter diastemma, wider and longer M¹ but smaller M³; chromosome number: 2n = 68–76; probably parapatric.

G. dolichurus. Similar size; chromosome number: 2n = 52, FN = 66; probably parapatric.

*Grammomys minnae*

Distribution Endemic to Africa, Somalia–Masai Bushland BZ. Recorded only from Ethiopia, at Bulcha Forest in the southern Rift Valley of Ethiopia and near Arba Minch at ca. 1800 m. Limits of distribution uncertain.

Habitat Gallery forest in bushy savanna (Hutterer & Dieterlen 1984).

Abundance Only known from the holotype and two others.

Remarks Nest built 10 m above the ground (H. Rupp in Hutterer & Dieterlen 1984).

Conservation IUCN Category: Vulnerable.

GENUS *Heimyscus* African Smoky Mouse

Heimyscus Misonne, 1969. Mus. Roy. Afrique Cent., Zool. 172: 125. Type species: *Hylomyscus fumosus* Brosset, Dubost, and Heim de Balsac, 1965.

Heimyscus fumosus.

Heimyscus is a monotypic genus restricted to Congo Basin in the Rainforest BZ. The characters of the genus are given in the species profile. *Heimyscus* bears close resemblance to *Hylomyscus*, the genus under which it was originally classified. External characters that distinguish this genus from *Hylomyscus* include longer thinner hindfeet, shorter Digits 1 and 5, smaller plantar tubercles and shorter tail. The molar teeth have pronounced cusps, more widely separated than in *Hylomyscus*. The affinities of the genus are uncertain. DNA/DNA hybridization studies indicate that *Heimyscus fumosus* is closer to *Hylomyscus stella* than to species of *Praomys*, *Myomyscus* (= *Myomys*) and *Mastomys* (Chevret *et al.* 1994), but mitochondrial cytochrome *b* analysis suggest that *Heimyscus* is divergent to *Hylomyscus* and more closely related to *Praomys* (Lecompte *et al.* 2002a). The single species is *Heimyscus fumosus*.

Justina C. Ray & Jay R. Malcolm

Heimyscus fumosus AFRICAN SMOKY MOUSE

Fr. Souris fumeuse; Ger. Afrikanische Rauchmaus

Heimyscus fumosus (Brosset, Dubost and Heim de Balsac, 1965). Biologia Gabonica 1: 154. Makokou, Gabon.

Taxonomy Originally described in the genus *Hylomyscus*, but later allocated to a new genus by Misonne (1969a), a classification confirmed by Robbins *et al.* (1980) on the basis of marked differences in cranial and external characters between *Heimyscus* and *Hylomyscus*. Synonyms: none. Chromosome number: 2n = 40 (Primus *et al.* 2006).

Description Small delicate mouse with soft short greyish-brown pelage. Dorsal pelage greyish-brown with a faint reddish tint in some individuals. Ventral pelage greyish-white and not clearly delineated from flanks. Eyes very small. Ears relatively tall. Vibrissae whitish, giving the snout a frosted or powdered appearance. Fore-

and hindfeet with short white hairs. Hindfeet narrow; Digit 5 reaches slightly beyond base of Digit 4, and is longer than Digit 1. Six relatively small metatarsal pads regularly distributed on plantar surface of hindfoot. Tail long (ca. 100% of HB), appears naked. Females significantly heavier than ♂♂ (Duplantier 1982, Ray 1996). Skull: similar to *Hylomyscus*; upper incisors opisthodont; anterior palatal foramina end well anteriorly to M¹; mean length of M¹–M³ shorter than in *Hylomyscus* (except for *H. parvus* [shorter] and *H. allenii* [similar]); cusps on molar teeth well-developed, mostly to a greater extent than in *Hylomyscus* (Figure 67). See Brosset *et al.* 1965 for full description. Nipples: 1 + 2 = 6.

Figure 67. Skull and mandible of *Heimyscus fumosus* (RMCA 10035). Details of the occlusal surface of the upper molar teeth are obscure and not included.

Geographic Variation None recorded.

Similar Species

Hylomyscus spp. Tail considerably longer than head and body; Digits 1 and 5 of HF longer (Digit 5 semi-opposable), and tubercles larger and positioned closer together; pelage reddish in colour, rougher in texture; ventral pelage whiter and more clearly delineated from flanks; partially sympatric with *H. aeta*, *H. alleni*, *H. parvus* and *H. stella*.

Praomys spp. Usually larger and heavier; tail longer; eyes larger; hindfeet broader.

Distribution Endemic to Africa, Rainforest BZ (West Central Region, Gabon Subregion). Recorded only from Gabon, S Cameroon, S Central African Republic and Congo (Brosset *et al.* 1965, Petter & Genest 1970, Robbins *et al.* 1980, Granjon 1991, Ray 1996, Malcolm & Ray 2000, Nicolas *et al.* 2003a).

Habitat In Central African Republic, found in all forest habitats except close to streams (Ray 1996), with slightly higher capture rates in undisturbed forest than in secondary forest along logging roads (Malcolm & Ray 2000). In Gabon, more abundant in forest than in secondary habitats bordering cultivation (Brosset *et al.* 1965) and slash-and-burn cultivation (J.-M. Duplantier unpubl.). In primary rainforest prefers micro-habitats with relatively dense understorey and open canopy (Duplantier 1989, Ray 1996).

Abundance In undisturbed rainforest at Makokou, Gabon, comprised 4.6–20.5% (mean 11.5%, $n = 549$; 9 spp.) of small rodents and was the second or third commonest species (after *Hylomyscus stella*) depending on the time of year; density 0.4–2.7/ha (mean 1.4/ha) (Duplantier 1989). In Dzanga-Sangha, Central African

Republic, comprised 9.7% of terrestrial captures from unlogged forest (10 of 103 captures), 6.6% from skid trails (9 of 136), 6.9% from secondary logging roads (12 of 174), 5.2% from primary logging roads (10 of 191); and 0% from mono-dominant *Gilbertiodendron dewevrei* forest (0 of 34) (J. Malcolm & J. Ray unpubl.; Malcolm & Ray 2000). At Mont Doudou, Gabon, comprised 8% ($n = 675$; 11 spp.) and 12% ($n = 802$; 10 spp.) of trapped small rodents during the course of 12 months, and was the fourth commonest species after *Hylomyscus stella*, *Hybomys univittatus* and *Praomys* cf. *misonnei* (Nicolas & Colyn 2003).

Adaptations Strictly terrestrial (Duplantier 1982; Malcolm & Ray 2000). Digs underground burrows or lives within tree-root cavities; burrows have two exit passages. Nests are filled with dead leaves (Duplantier 1982).

Foraging and Food Diet composed of ca. 50% insects and 50% fruit seeds and pulp, with seeds especially common. Arthropods (cockroaches, caterpillars, beetle and fly larvae, termites and myriapodes) present in all stomachs examined (Duplantier 1982).

Social and Reproductive Behaviour In Makokou, Gabon, home-ranges slightly larger for ♂♂ ($2900 \pm 1608 \text{ m}^2$, $n = 12$) than ♀♀ ($2500 \pm 776 \text{ m}^2$, $n = 12$). Maximum recapture distance for ♂♂ averaged 50.5 m ($n = 22$), and for ♀♀ 37.5 m ($n = 30$) (Duplantier 1982).

Reproduction and Population Structure In Gabon, reproductive activity evident throughout the year with a peak of activity during the dry season (Jan–Mar) (Duplantier 1989). In another part of Gabon, ♀♀ were only reproductively active from Aug to Mar (Nicolas & Colyn 2003). Litter-size: 2.1 (1–3, $n = 7$; Dzanga-Sangha, Central African Republic; J. C. Ray & J. R. Malcolm unpubl.), 2.6 (2–4, $n = 7$; Gabon; Nicolas & Colyn 2003), 3 and 4

Heimyscus fumosus

($n = 2$; Makokou, Gabon; Dubost 1968, Duplantier 1982), 3 ($n = 1$; Kouilou Basin, Congo; Granjon 1991). Average number of captures of ♀♀ significantly greater than for ♂♂ at Makokou, Gabon (Duplantier 1982). In SW Gabon, the sex ratio not significantly different overall, between seasons or age classes (Nicolas *et al.* 2003b). The age class composition differed between seasons, the population experiencing a gradual ageing from Apr to Sep, simultaneously with an increase in mean body weight (Nicolas *et al.* 2003b). In SW Gabon, ♀♀ reached sexual maturity later than ♂♂ (Nicolas *et al.* 2003b).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

GENUS *Hybomys*

Forest Mice

Hybomys Thomas, 1910. Ann. Mag. Nat. Hist., ser. 8, 5: 85. Type species: *Mus univittatus* Peters, 1876.

Hybomys univittatus.

Figure 68. Skull and mandible of *Hybomys trivirgatus* (HC 977).

This genus contains six species of medium-sized, dark-coloured terrestrial rodents (Table 33), representing two well-defined subgenera: *Hybomys* with four species (*H. badius*, *H. basili*, *H. lunaris* and *H. univittatus*) and *Typomys* with two species (*H. planifrons* and *H. trivirgatus*). Their collective distribution is closely tied to the distribution of the Rainforest BZ (as well as montane rainforest). In West Africa, species in the genus are recorded from SW Guinea to S Nigeria (excluding the Dahomey Gap); in central Africa, from Cameroon to S Uganda, and southwards through Gabon, Congo and DR Congo to NC Zambia. They are found generally at lower altitudes (100–1000 m) but as high as 2600 m in the Rwenzori Mts.

Species in the genus are medium-sized murines with variable amounts of dark dorsal striping. The dorsal pelage is some shade of brown, with overtones ranging from drab yellowish to dark reddish, and the ventral pelage is typically dull whitish-grey. A single mid-dorsal black stripe is always present, sometimes weakly marked; and in *H. trivirgatus* it is bordered by an additional stripe on each side. The pelage is moderately soft and short; juvenile pelage colour is like that of adults but the texture softer and finer. Pinnae are darkly pigmented and thinly haired. Digits 1 and 5 of the hindfoot are relatively short, extending only to the base of Digits 2–4; plantar surfaces are black and hairless, with five plantar pads (hypothecar absent). Tail is shorter than

Table 33. Species in the genus *Hybomys* (see also Figure 69). Arranged according to number and conspicuousness of stripe(s).

| Species | Dorsal stripe(s) | Position of stripe(s) | Subgenus ^a | Chromosome number | Distribution and notes |
|-----------------------|--|--|-----------------------|-------------------|--|
| <i>H. trivirgatus</i> | Three, inner usually conspicuous; outer usually inconspicuous (see text) | Inner stripe: forehead to base of tail.
Outer stripes: shoulder to base of tail | <i>Typomys</i> | 2n = 40, 42 | Sierra Leone – W Nigeria |
| <i>H. planifrons</i> | One, conspicuous | Neck to base of tail | <i>Typomys</i> | 2n = 35, 38, 39 | Guinea – Côte d'Ivoire |
| <i>H. univittatus</i> | One, sometimes inconspicuous | Neck/shoulders to base of tail | <i>Hybomys</i> | 2n = 44, 46, 48 | SE Nigeria – Uganda – NW Zambia |
| <i>H. badius</i> | One, inconspicuous | Neck to base of tail | <i>Hybomys</i> | n. d. | S Cameroon only |
| <i>H. basilioi</i> | One, inconspicuous | Mid shoulders to base of tail | <i>Hybomys</i> | n. d. | Bioko I. only. Largest species (mean HB: 137 mm) |
| <i>H. lunaris</i> | One, inconspicuous | Mid shoulders to rump | <i>Hybomys</i> | 2n = 48 | Rwenzori Mts only. Smallest species (HB: 108 mm) |

^a See details in genus profile.

head and body (T: ca. 75–85% of HB), dusky to almost black. Skull characters include the following: moderate size (GLS: ca. 31–36 mm), braincase lacking prominent ridging even in old animals; interorbital region with slight supraorbital shelf and low beaded edges; zygomatic arches parallel-sided, low-slung over their mid-section; and auditory bullae medium-sized. The molars are strongly cuspidate, acuminate until heavily worn; M³ about one-half the size of M²; cusp t3 of M¹ smaller than t1; t7 absent; t9 variable in size and occurrence on M¹ and M² depending on the species; M³ with large t1 and without a t3; anteroconid of M₁ deeply bifurcate, with or without an anteromedial conulid; and the development of accessory cusps on labial cingula variable according to the species. Upper incisors opisthodont, without grooves; anterior surface yellow to yellowish-orange (Figure 68).

All species appear to be predominantly insectivorous, mostly diurnal and generally solitary in habits. Habitats within the Rainforest BZ include primary and secondary forest, densely vegetated 'gaps' formed by natural treefalls and by logging, and swampy areas with leaf litter and dense vegetation. *Hybomys* is mostly a rare genus, typically comprising <2% of the small rodent community and occasionally up to 30% when conditions are temporarily very favourable.

Variation of many characters within *Hybomys* concords with the two subgeneric divisions (e.g. see Rosevear 1969, Van der Straeten & Verheyen 1982, Carleton & Robbins 1985, Verheyen & Van der Straeten 1985). (1) Subgenus *Hybomys*: pectoral mammae present; skull profile evenly arched; zygomatic plate broad and vertical; anterior palatal foramina longer; alisphenoid strut present; accessory molar cusps usually present; M1/m1 roots = 5/5; limited to the

West Central, East Central and South Central Regions of the Rainforest BZ. (2) Subgenus *Typomys*: pectoral mammae absent; skull flatter; zygomatic plate narrow and slanted; anterior palatal foramina shorter; alisphenoid strut absent; accessory molar cusps usually absent; M1/m1 roots = 3/2; limited to the Western Region of the Rainforest BZ (sometimes called the 'Upper Guinea Forests') and the West Central Region (West Nigeria Subregion).

In view of the many morphological contrasts and their distributions within different biogeographic regions, some systematists have arranged *Hybomys* and *Typomys* as separate genera (Thomas 1911a, Van der Straeten 1984). Others have viewed their relationship as sister taxa, expressed at the level of distinctive subgenera (Allen 1939, Carleton & Robbins 1985), with general affinity to members of the arvicanthine assemblage (Ellerman 1941), in particular *Dephomys* (Misonne 1969a). Immunological data have supported the close relationship of *Hybomys univittatus* and *Stochomys longicaudatus* among 15 African murid genera studied, but other taxa critical to the issue of *Hybomys* and *Typomys* as genera or subgenera were not included (Watts & Baverstock 1995a). Resolution of the appropriate taxonomic ranking accorded to *Hybomys* and *Typomys* will require additional phylogenetic studies that include other rainforest rats, especially *Dephomys* and *Stochomys*.

The species are distinguished on the form and number and position of stripes on the back (Figure 69), cranial size and shape, development of the anterior palatal foramina, presence/absence of certain molar cusps, and karyological differences.

Michael D. Carleton

Figure 69. Schematic diagram of the stripes on the dorsal pelage of *Hybomys* spp.

(a) *H. badius*, (b) *H. basilioi*, (c) *H. lunaris*, (d) *H. planifrons*, (e) *H. trivirgatus* (Sierra Leone), (f) *H. trivirgatus* (Nigeria), (g) *H. univittatus* (after original by D. C. D. Happold). In some individuals, stripes may be inconspicuous or even absent (see text for details).

Hybomys badius CAMEROON FOREST MOUSE (CAMEROON HIGHLAND HYBOMYS)

Fr. Rat forestier du Cameroon; Ger. Kamerun-Streifenmaus

Hybomys badius Osgood, 1936. Zool. Ser. Field Mus. Nat. Hist. 20: 254. Southwest slope of Mt Cameroon, Cameroon.

Taxonomy Subgenus *Hybomys*. Originally described as a subspecies of *Hybomys univittatus*. The form *eisentrauti* was described as a separate species (Van der Straeten & Hutterer 1986) but is tentatively included in *H. badius* by Musser & Carleton (2005), an action that needs further study and documentation. Synonyms: *eisentrauti*. Subspecies: none. Chromosome number: not known.

Description Medium-sized dark brown forest mouse with single mid-dorsal stripe. Pelage silky and shiny; hairs fine, ca. 8 mm. Dorsal pelage dark reddish-brown to very dark brown, faintly flecked with yellowish-brown or chestnut-brown; hairs dark grey with yellowish-brown subterminal band and black tip; numerous slightly longer pure black hairs. Black mid-dorsal stripe from between ears or neck to base of tail; stripe weakly defined but mostly clearly visible. Ventral pelage greyish-brown, often tinged with buff; hairs pale grey at base, whitish-grey or buff at tip. Colour of ventral pelage not clearly delineated from colour of flanks. Head similar in colour to dorsal pelage. Head and neck thickset, muzzle blunt. Ears rounded, darkly pigmented. Fore- and hindfeet blackish-brown; soles of hindfeet black. Tail long (ca. 85% of HB) ringed with small blackish scales; numerous short dark bristles. Nipples: 1 + 2 = 6.

Geographic Variation The form *eisentrauti* (from Mt Lefo and Mt Oku, Cameroon) has greyish-white ventral pelage, and the indistinct mid-dorsal stripe usually extends from shoulders or mid-back to base of tail.

Similar Species

H. univittatus. Similar in size; hindfoot on average slightly longer; dorsal colour less dark, mid-dorsal stripe more obvious; rainforests of S Cameroon.

Distribution Endemic to Africa. Rainforest BZ (West Central Region, Eastern Nigeria sub-region). Known only from Mt Cameroon, Rumpi Hills and Mt Kupé (*badius*), and from Mt Lefo and Mt Oku in the Bamenda highlands (*eisentrauti*). Probably also other highlands in the Mamfe Region, W Cameroon (Eisentraut 1963, 1973).

Habitat Dense lowland forest (lowest altitude 30 m) and montane forest up to 2000 m.

Abundance Very common on Mt Cameroon (Eisentraut 1973).

Remarks Strictly terrestrial; active at day and night (Eisentraut 1973). Partly carnivorous; the stomach of one animal from Mt Oku

*Hybomys badius*

contained 60% animal matter (O. Fülling pers. comm.). Pregnant ♀♀ in Oct–Jan (no data for other months). Embryo number: 1.8 (1–2, mode 2; n = 6). Subadults were observed at the end of Oct and in Nov (Eisentraut 1973).

Conservation IUCN Category: Endangered.

***Hybomys basilioi* BASILIO'S FOREST MOUSE (BIOKO HYBOMYS)**

Fr. Rat forestier de Basilio; Ger. Basilius Streifenmaus

Hybomys basilioi Eisentraut, 1965. Zool. Jahrb. Syst. 92: 20. Mocaltal, Fernando Poo (= Bioko I., Equatorial Guinea). 1200 m.

Taxonomy Subgenus *Hybomys*. Originally described as a subspecies of *H. univittatus*; raised to specific rank by Van der Straeten (1985). Synonyms: none. Chromosome number: not known.

Description Medium-sized dark mouse, with indistinct mid-dorsal stripe on rump. Similar in general colour and form to other species in genus. Pelage long, soft and shiny. Dorsal pelage dark reddish-brown, slightly speckled with yellowish-brown; hairs grey at base, black at tip or with subterminal band of yellowish-brown and black tip. Black mid-dorsal stripe, if present, very inconspicuous, from mid-back to base of tail. Ventral pelage whitish-grey, colour usually limited to close to mid-ventral line; hairs grey at base, off-white or pale grey at tip. Other characters similar to other species in genus. Males are slightly larger than ♀♀.

Geographic Variation None recorded.

Similar Species All other *Hybomys* species are on average smaller and occur on the mainland.

Distribution Endemic to Africa. Occurs only on Bioko I. (Equatorial Guinea), and the only species of *Hybomys* on the island; 450–2000 m.

Habitat Closed and montane forests, also forest edges in dense cover (Eisentraut 1965).

Abundance In suitable habitats the species may be locally abundant.

Remarks Terrestrial. Mainly nocturnal but also active during the day (Eisentraut 1965). Pregnant ♀♀ found in Oct and Dec. Litter-size: 1–2 (Eisentraut 1965, 1973).

Conservation IUCN Category: Endangered.

Hybomys lunaris (Thomas, 1906). Ann. Mag. Nat. Hist., ser. 7, 18: 145. Mubuku Valley, Rwenzori East, Uganda. 6000 ft (1830 m).

Taxonomy Originally described as *Mus univittatus lunaris*. Subgenus *Hybomys*. Although *lunaris* was described as a subspecies, it is now raised to specific rank on the basis of chromosomal traits (Verheyen & Van der Straeten 1985) and morphometric analyses (Van der Straeten *et al.* 1986). Carleton & Robbins (1985) suggested that *lunaris* from the region of the type locality is at present confined only to that area, a statement confirmed by Kerbis Peterhans *et al.* (1998). The variability

within the species (and hence its geographic range) is uncertain. The populations named as *H. lunaris* by Dieterlen (1985a, b) are now provisionally considered to represent *H. univittatus*. Synonyms: none. Chromosome number: 2n = 48 (Rwanda; Verheyen & Van der Straeten [1985]; however, this may not represent *H. lunaris* as defined here. See Musser & Carleton 2005).

Description Thomas (1906) wrote: '[This species has the] general characters of the typical western *M. univittatus*, but size smaller and colour more olivaceous, not turning rufous on the rump, which is blackish olivaceous. Belly-hairs greyish tipped with buffy; a line down outer edge of thighs also buffy. Dorsal streak not sharply defined and not extending on to neck and head. Upper surface of hands blackish-brown, of feet rufous-brown. Tail practically naked, black above, rather lighter below. Skull similar to that of true *univittatus*, but smaller and lighter throughout. Molars decidedly narrower.' Musser & Carleton (2005) referring to the holotype and to two specimens in the USNM from Kanyawara, a place near to the type locality, state that these 'precisely fit Thomas's description in their colouration, delicate skull, and small size. These two specimens contrast sharply with the larger robust skulls seen in our examples from Uwinka, Rwanda, the same locality where Verheyen and Van der Straeten obtained karyotypic preparations.'

Geographic Variation None recorded.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Restricted to the Rwenzori Mts (Kerbis Peterhans *et al.* 1998). Van der Straeten *et al.* (1986) enlarged the range to include NE and E DR Congo, W Uganda and Rwanda. However, individuals from the enlarged area are not representative of true *lunaris*, which (morphologically) is known only from the Rwenzori Mts (Musser & Carleton 2005).

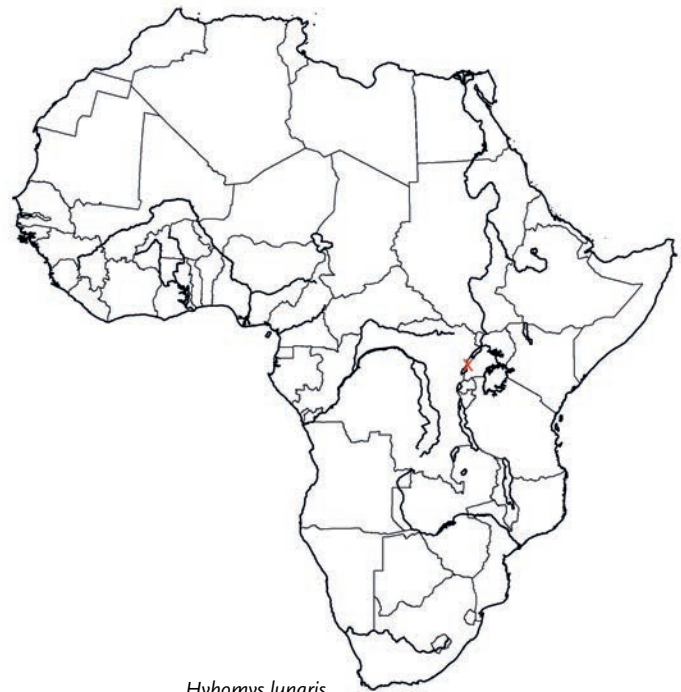

Habitat Montane forest on the eastern slopes of Rwenzori Mts, mostly between 1830 and 2440 m (Thomas & Wroughton 1910, Misonne 1963). On the western slopes of Rwenzori Mts, the altitudinal range of the montane forest is confined to 1900–2100 m (Misonne 1963).

Abundance R. B. Wroughton (in Thomas & Wroughton 1910) wrote: 'This was a rare species on Rwenzori and only two examples were obtained during many months' continuous trapping'.

Remarks Apparently no other information available.

Conservation IUCN Category: Vulnerable.

Montane forests on the Rwenzori Mts are under threat.

Hybomys planifrons LIBERIAN FOREST MOUSE (LIBERIAN FOREST HYBOMYS)

Fr. Rat forestier à front plat; Ger. Millers Streifenmaus

Hybomys planifrons (Miller, 1900). Proc. Washington Acad. Sci. 2: 641. Mount Coffee, 400–500 ft (122–152 m), Liberia.

Taxonomy Subgenus *Typomys*. Originally described as *Arvicanthis planifrons*, but subsequently considered to be a subspecies of either *Hybomys univittatus* (Allen 1939) or *H. trivirgatus* (Rosevear 1969). Re-established as a valid species on the basis of various cranial and dental attributes, and a different karyology from other species in the genus (Carleton & Robbins 1985). Synonyms: none. Chromosome number: 2n = 35, 38, 39; FN = 40, 42 (Tranier & Dosso 1979, Carleton & Robbins 1985).

Description Medium-sized, dark-coloured murine with a single mid-dorsal black stripe that extends from the level of the pinnae to base of tail. Dorsal pelage rich, dark brown; hairs dark grey at base with rufous subterminal band. Ventral pelage similarly dark; hairs dark grey at base with warm buff to ochraceous tips. Ears short and darkly pigmented, moderately covered with fine hairs. Upper surface of hindfeet dusky brown, plantar surfaces black and hairless. Tail short (ca. 75–80% of HB), sparsely haired, black all around or only slightly paler underneath. Skull of the *Typomys* configuration (see

Genus profile); anterior palatal foramina relatively long and reaching the level of the front edge of M^1 ; bony palate correspondingly shorter; interorbital constriction relatively narrow; cusp $t9$ of M^1 typically absent or present ($<7\%$) only as a bulge of the enamel crest linking $t6$ – $t8$. Sexual dimorphism in size negligible (Carleton & Robbins 1985). Nipples: $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species

H. trivirgatus. Dorsum with one dark mid-dorsal stripe bordered on each side by a less well-defined black stripe, from level with pinna (or shoulders/mid-back in some parts of range) to base of tail; skull with shorter anterior palatal foramina that terminate anteriorly to the level of M^1 ; interorbital constriction broader; cusp $t9$ of M^1 usually present; may be sympatric with *H. planifrons* from E Sierra Leone to SW Côte d'Ivoire.

Distribution Endemic to Africa. Rainforest BZ (Western Region). Recorded from SW (Kounankan Massif) and SE (Mt Nimba region) Guinea, Sierra Leone, Liberia and SW Côte d'Ivoire west of the Sassandra R. (Carleton & Robbins 1985, Barnett *et al.* 1996). Altitudinal range from ca. 100 m to 1000 m (Grubb *et al.* 1998).

Habitat Primary and secondary rainforest, and riverine forest, typically in micro-habitats with dense, moist ground cover. In Nimba Mts, Liberia, collected in dense vegetation of rainforest at lower altitudes than *H. trivirgatus* (Coe 1975). In Sierra Leone, found in moist semi-deciduous forest with luxuriant understorey and lush ground cover dominated by stands of *Marantachloa* sp. (Marantaceae) (Carleton & Robbins 1985), and in cocoa plantations with abundant vegetation (Grubb *et al.* 1998).

Abundance No census information available but locally restricted and uncommon (e.g. $<1\%$ of small rodents trapped in Outamba-Kilimi region, N Sierra Leone; M. D. Carleton unpubl.).

Remarks Terrestrial. Limited trapping records indicate that these striped forest mice are diurnal (Sierra Leone; Carleton & Robbins 1985). Forages on ground. Mainly insectivorous, but also feeds on fruits and other vegetable matter (Sierra Leone: Grubb *et al.* 1998). Two embryos recorded in one specimen (label, USNM) from Sierra Leone.

Hybomys trivirgatus THREE-STRIPED FOREST MOUSE (WEST AFRICAN HYBOMYS)

Fr. Rat forestier à trois bandes dorsale; Ger. Dreistreifenmaus

Hybomys trivirgatus (Temminck, 1853). Esquisses zoologiques sur la Côte de Guinée. Part I, Mammifères, p. 159. Dabocrom, Ghana.

Taxonomy Originally described in the genus *Mus*. Subgenus *Typomys*. *Hybomys trivirgatus* formerly included Miller's (1900) *planifrons* as a well-defined subspecies (e.g. Rosevear 1969, Misonne 1974) until *planifrons* was reinstated to a full species based on morphological and karyotypic differences (Carleton & Robbins 1985). Ingoldby (1929) described *pearsei* (type locality = Lagos, Nigeria) as a subspecies of *H. trivirgatus*, an arrangement considered invalid by Rosevear (1969) and Happpold (1987). *Hybomys trivirgatus* is now considered to be a

monotypic species whose closest relative is *H. planifrons*, the other West African member of the subgenus *Typomys* (Carleton & Robbins 1985). Synonyms: *pearsei*. Subspecies: none. Chromosome number: $2n = 40, 42, 43$; $FN = 40, 42, 43$ (Tranier & Dosso 1979, Carleton & Robbins 1985, Verheyen & Van der Straeten 1985).

Description Medium-sized rodent with three dark dorsal stripes usually visible. Dorsal pelage yellowish- to greyish-brown and finely

*Hybomys trivirgatus*

speckled; hairs pale grey at base with ochraceous subterminal band. Mid-dorsal stripe black and prominent, usually extending from crown or forehead to rump but sometimes from shoulders/mid-back to rump in some populations; lateral stripes pale dusky and shorter, sometimes only faintly defined in certain individuals or populations (especially in Nigeria). Ventral pelage variable, typically drab greyish-white, occasionally with extensive suffusion of buff-tipped hairs. Upper surface of hindfeet pale brown; plantar surface black and naked. Tail long (ca. 80% of HB), dark brown to blackish, usually indistinctly paler ventrally. Skull of the *Typomys* configuration (see Genus profile); interorbital constriction relatively broad; anterior palatal foramina short and wide, not reaching the level of the anterior edge of M^1 , and bony palate correspondingly long; $t9$ usually present on M^1 (ca. 75–95% of specimens). Sexual dimorphism in size negligible (Van der Straeten & Verheyen 1982). Nipples: $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species

H. planifrons. Lateral stripes absent and mid-dorsal stripe terminating anteriorly about the level of the pinnae; interorbital constriction narrower; anterior palatal foramina longer; cusp $t9$ lacking on M^1 and M^2 ; may occur sympatrically with *H. trivirgatus* from E Sierra Leone to SW Côte d'Ivoire.

Distribution Endemic to Africa. Rainforest BZ (Western Region and West Central Region [Western Nigerian Subregion]). Recorded from E Sierra Leone to SW Nigeria, west of the Niger R. (Carleton & Robbins 1985, Happold 1987, Grubb *et al.* 1998). Not recorded

in S Togo and Benin (Dahomey Gap). Altitudinal range from near sea level to 1200 m (Coe 1975).

Habitat Undisturbed rainforest (Happold 1975b, 1977); also recorded in cocoa plantations and secondary bush adjacent to forest (Jeffrey 1977).

Abundance Rarely encountered using typical field census methods, e.g. comprised only 1–2% of small terrestrial rodents at various sites in SW Nigeria (Happold 1975b, 1977). Higher relative abundances recorded elsewhere, e.g. 11% in Ghana (Cole 1975).

Adaptations Terrestrial. Activity reported as diurnal (07:00–16:00h) (Ghana; Cole 1975) and as both diurnal and nocturnal (Nigeria; Happold 1977).

Foraging and Food Forages in natural thickets along valley bottoms and valley slopes, avoiding bare ground and retreating to fallen logs when disturbed. Mainly insectivorous (ants, termites, beetles, orthopterans) but feeds on some vegetable material (Ghana; Cole 1975).

Social and Reproductive Behaviour Trapping data suggest that animals live in small groups because individuals were frequently found in the same or adjacent traps within a restricted area (Cole 1975, Happold 1977).

Reproduction and Population Structure Pregnant ♀♀ recorded mainly in wet season (Mar, Jul and Sep). Litter-size: 2.8 (2–3, $n = 4$; Nigeria; Happold 1974, 1987).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

***Hybomys univittatus* ONE-STRIPED FOREST MOUSE (PETERS'S HYBOMYS)**

Fr. Rat forestier bai; Ger. Einstreifenmaus

Hybomys univittatus (Peters, 1876). Monatsber. K. Preuss. Akad. Wiss. Berlin, p. 479. Dongila, Gabon.

Taxonomy Originally described in the genus *Mus*. Subgenus *Hybomys*. The definition of this form is uncertain. There is considerable morphological and karyotypic variation among populations assigned to *H. univittatus*, with several forms previously classified as subspecies now elevated to species level (Carleton & Robbins 1985, Verheyen & Van der Straeten 1985). The populations named as *H. lunaris* by Dieterlen (1967b, 1985a, b) are now provisionally considered to be *H. univittatus* (see also *H. lunaris*). Synonyms: *rufocanus*. Subspecies: none. Chromosome number: $2n = 44, 46, 48$ (Carleton & Robbins 1985, Verheyen & Van der Straeten 1985).

Description Medium-sized dark mouse with one black mid-dorsal stripe. Pelage soft and sleek; hairs long, 12–14 mm. Dorsal pelage dark reddish-brown to very dark brown, with yellowish-brown speckling. Hairs dark grey at base with black tip, or with subterminal band of yellowish-brown and black tip. Black mid-dorsal stripe from nape of neck or shoulders to base of tail (sometimes rather inconspicuous). Ventral pelage tawny to whitish-grey, hairs grey with off-white, buff or pale brown tip. Colour of dorsal pelage and ventral pelage clearly delineated on flank. Head and neck thickset, muzzle blunt. Ears small, very round and appearing naked. Eyes relatively large. Fore- and hindfeet black. Digits 1 and 5 reach only to the base of Digits 2, 3 and 4. Digit 5 slightly longer than Digit 1. Soles of hindfeet shiny black with five metatarsal pads on plantar surface. Tail long (ca. 85% of HB), very black, mostly naked, with dense rings of very short bristles; may be slightly bicoloured. Nipples: $1 + 2 = 6$.

Geographic Variation Colour of dorsal and ventral pelage variable, even at any given locality; dorsal stripe sometimes not detectable.

Similar Species

Hybomys badius. Pelage shorter; mid-dorsal stripe usually longer and often more visible; range very restricted (highland areas of Cameroon).

H. lunaris. Lighter, more delicate skull (E DR Congo only).

H. trivirgatus and *H. planifrons*. West Africa only.

Distribution Endemic to Africa. Rainforest BZ (West Central [Eastern Nigeria and Gabon Subregions], East Central and South Central Regions), and some outlier forests in Rainforest–Savanna Mosaics. Recorded from SE Nigeria (east of the Niger R.), Cameroon, Gabon, extreme S Central African Republic, N DR Congo, SC Uganda, W Rwanda and extreme NW Zambia (Delany 1975, Ansell 1978, Carleton & Robbins 1985, Happold 1987, Ray 1996). Outlier populations in C DR Congo and S DR Congo/NW Zambia (Ansell 1978, Carleton & Robbins 1985). Replaced by *H. trivirgatus* and *H. planifrons* in West Africa, west of the Niger R.

Habitat Rainforest, especially where gaps in the canopy allow dense herbaceous cover on the ground. Readily takes advantage of both natural and human-made secondary habitats within the Rainforest BZ,

provided cover is present. In SW Central African Republic, prefers habitats with dense understorey and low canopy cover (Ray 1996). Capture rates were higher along primary and secondary forestry roads than along narrower, less-damaged tracks (Malcolm & Ray 2000). In Kibale Forest, Uganda, population numbers were higher in gaps in mature and logged forests than in non-gaps, and where ground cover was most dense. Number of captures increased with increasing forest patch size (Struhsaker 1997). Frequently associated with moist forests near rivers or swamps, characterized by rich herbaceous flora, abundant leaf litter and heavy shade (Sanderson 1940, Delany 1964a, Kingdon 1974). Present in gallery forests or montane forests at elevations up to ca. 2000 m (Rosevear 1969, Carleton & Robbins 1985).

Abundance Abundance varies greatly according to location and forest disturbance. Generally an uncommon species although it is generally the commonest species in forests with extensive gaps. During 44 months of trapping in Kibale Forest, Uganda, density and relative abundance increased significantly with increased logging intensity, e.g. mean density was 0.14 individuals/ha (comprising 1.6% of all rodent species captured) in unlogged forest; 3.02/ha (22.5%) in lightly logged forest; and 4.14/ha (26.7%) in heavily logged forest (Struhsaker 1997). In SW Central African Republic, relative abundance was 0% along streams ($n = 200$), 0.7% in mono-dominant *Gilbertiodendron dewevrei* forest ($n = 406$), 4.1% ($n = 458$) in unlogged mixed-species forest, and 12.6% of all captures ($n = 704$) along secondary logging roads. In E DR Congo, it represented 15.1% of total captures ($n = 93$) in 'primary' forest and 9.5% ($n = 169$) in cultivated secondary bush (Rahm 1967). In undisturbed rainforest at Makokou, Gabon, relative abundance on

*Hybomys univittatus*

a 9-ha study site ranged from 0% to 4.2% (mean: 2.16%, 21 of 971 captures) during six trapping sessions over 15 months (Duplantier 1989). It was the most commonly captured species in an undisturbed forest in SW Gabon, representing 24% of 1531 captures (Nicolas & Colyn 2003). In undisturbed mixed forest in Ituri Forest, DR Congo, comprised 19 of 60 (31.7%) individuals captured (Gubista 1999).

Adaptations Terrestrial (Genest-Villard 1978a, Duplantier 1982, Malcolm & Ray 2000), although a good swimmer (Thomas 1888a). Diurnal and nocturnal (Rahm 1967, Rosevear 1969, Genest-Villard 1978). Trapping near L. Kivu, DR Congo, yielded 60% of total captures ($n = 30$) at 08:00h (caught overnight), 16.7% at 12:00h and 23.3% at 17:00h (Rahm 1967). Individuals live and breed in burrows found in cavities under tree roots, stumps, or rotting logs (Kingdon 1974, Duplantier 1982). Nests are made from twigs (Genest-Villard 1978b) or leaves (Duplantier 1982). An individual may have three or more burrows (with those of a ♀ often as close as 10 m apart), and there is a tendency to use one burrow more than the others (Genest-Villard 1978b). Males usually spend several nights in the same burrow, while ♀♀ seldom spend more than two consecutive nights in the same burrow unless they have young. Males emerge from the burrow between 07:20h and 08:50h, have resting periods in mid-morning and late afternoon, and return to the burrow for the night between 17:45h and 18:05h. Individuals cover about 500 m each day with a mean speed ranging from 80 to 90 cm/min in the afternoon and 110 cm/min in the mornings. Females are not as active as ♂♂, and cover shorter distances, generally not wandering more than 50 m from their burrow (Genest-Villard 1978b).

Foraging and Food Omnivorous and insectivorous; diet varies geographically. At M'Baiki, Central African Republic (Genest-Villard 1980), diet varied seasonally: 70% insects, 25% fruit pulp and 5% seeds in wet season, and 61% insects, 21% fruit pulp and 17% seeds in dry season. Most of the insect food consisted of termites and ants. At least 30 species of fruit were eaten in the wet season, fewer during the dry season, as well as cultivated fruit and seeds, particularly during the dry season. Although leaves are not important components of stomach

contents, feeding observations indicated that they were regularly sought after and consumed, although in small quantities. Radio-collared individuals foraged beneath the leaf litter or fallen woody debris, and insects were snapped up opportunistically when encountered (Genest-Villard 1980). In Makokou, Gabon, during the wet season, diet was mostly fruit pulp, although arthropods (cockroaches, caterpillars, beetle and fly larvae, ants, termites and myriapods) were present in 99% of stomachs, usually in small quantities. In the dry season, proportionately less pulp and more seeds and insects were consumed (Duplantier 1982). In Kibale Forest, Uganda, almost 70% of stomach contents comprised fruit pulp and seeds; other identifiable items of the diet were equal proportions of insects and herbaceous matter. Feeding experiments on captive individuals demonstrated a preference for dried seeds rather than fresh seeds and fruit (Struhsaker 1997). Reported to feed opportunistically from fruit scattered on the ground by arboreal frugivorous primates and birds (Kingdon 1974).

Social and Reproductive Behaviour Mainly solitary. Home-range of radio-collared individuals was 4.5–6.1 ha ($n = 6$ ♂♂) and 1.4–1.8 ha ($n = 4$ ♀♀). Home-ranges of neighbouring ♂♂ do not overlap and ♂♂ do not tolerate other ♂♂ in their home-range, suggesting strong territoriality. A ♂ gives chase and bites intruders within his home-range. There is little overlap in the ranges of any individuals, although the home-ranges of one or more ♀♀ may overlap with that of a ♂. Males exhibit home-range fidelity throughout their life-span, whereas ♀♀ may leave one home-range for another. Individuals do not sleep together in the same burrows. Young ♂♂ and ♀♀ disperse from their natal area (Genest-Villard 1978b).

Reproduction and Population Structure In Central African Republic, reproductive activity in ♂♂ and ♀♀ occurred at all times of the year, with a peak of activity during wet season (Aug–Nov) (Ray 1996). In E DR Congo, reproduction corresponded with the end of the wet season when fruiting is at its peak, and reproductive activity was not evident during dry season (Rahm 1970). Gestation: 29–31 days (Petter & Genest 1967). Litter-size: 2.5 (1–5, $n = 38$; Makokou, Gabon; Dubost 1968); 2.6 (2–6, $n = 10$; Dzanga-Sangha, Central African

Republic; J. C. Ray & J. R. Malcolm unpubl.); 2.6 (2–4, n = 20; SW Gabon; Nicolas & Colyn 2003). Mean body weights in Dzanga-Sangha were significantly lower in dry season than in the wet season. Head, body and tail fully grown at about Week 20 (Petter & Genest 1967). First parturition, on average, at 4.5 months of age (range: 11 weeks to 7 months). Male life-span ca. 12 months (Genest-Villard 1978b).

Predators, Parasites and Diseases Remains found in scats of mongooses and other small carnivores in Dzanga-Sangha, Central African Republic (Ray 1998). Hunted by pygmies using crossbows, especially in the wet season (Genest-Villard 1980).

Conservation IUCN Category: Least Concern.

GENUS *Hylomyscus*
Wood Mice

Hylomyscus Thomas, 1926. Ann. Mag. Nat. Hist., ser. 9, 17: 174. Type species: *Epimys aeta* Thomas, 1911.

The genus contains eight species (Table 34) and is endemic to Africa. It is widely distributed in lowland and montane rainforests of tropical Africa from Guinea to Angola and DR Congo, and in afroalpine habitats of East African mountains.

Species of *Hylomyscus* are very small to small arboreal mice, soft-furred, with a very long tail, slender and relatively short hindfeet, and large round ears. The skull is relatively broad, smooth and rounded, with small zygomatic plate, small auditory bullae and small narrow molars; upper incisor teeth are pro-odont, orthodont or opisthodont (depending on the species); and anterior palatal foramina

end well anterior to M¹ or level with anterior end of M¹ (Figure 70). Wood Mice are agile climbers, using the digits of the hindfeet to grip small branches and twigs. Digit 5 of the hindfoot is opposable or semi-opposable. Wood Mice are exclusively nocturnal and have an omnivorous diet. In many habitats only one species of *Hylomyscus* is present, but in others 3–4 species appear to be sympatric.

Figure 70. Skull and mandible of *Hylomyscus stella* (HC 890).

| | Colour of ventral pelage | Distribution |
|--|---------------------------------|--|
| | Dark grey at base, brown at tip | Scattered localities in Gabon, Congo, Central African Republic, S Cameroon, N DR Congo |
| | Grey at base, white at tip | Sierra Leone to Togo. Cameroon to Central African Republic |
| | Grey at base, white at tip | Rainforest. Widespread from Nigeria to Kenya |
| | Grey at base, white at tip | Rainforest BZ of central Africa |
| | Grey at base, white at tip | Angola; perhaps SE DR Congo |
| | Grey at base, white at tip | Mt Oku, Cameroon |
| | Grey at base, white at tip | E DR Congo, Rwanda, Burundi, Uganda, Kenya, Tanzania, WC Angola. Highland |
| | Pure white | Liberia, Côte d'Ivoire and Ghana |

Hylomyscus was previously treated as a subgenus of *Rattus* (e.g. by Ellerman 1941) or of *Praomys* (e.g. by Davis 1965 and Misonne 1974), but its generic status is now recognized by most authorities (e.g. Allen 1939, Hatt 1940a, Heim de Balsac & Aellen 1965, Rosevear 1966, 1969, Robbins *et al.* 1980). The genus is part of the monophyletic 'Praomys group' comprising *Praomys*, *Myomyscus* (formerly *Myomys*), *Mastomys* and *Hylomyscus* (Chevret *et al.* 1994), which is more closely related to *Mus* than to *Rattus*. Analysis of skeletal and dental traits

(Lecompte *et al.* 2002a), mitochondrial cytochrome *b* (Lecompte *et al.* 2002b) and other characters show that the first three genera cluster together and that *Hylomyscus* is clearly separate and monophyletic.

Species in the genus are distinguished primarily by size, tail length and pelage colour.

Fritz Dieterlen

Hylomyscus aeta BEADED WOOD MOUSE (BEADED HYLOMYSCUS)

Fr. Rat à poil doux de Thomas; Ger. Perlen-Waldmaus

Hylomyscus aeta (Thomas, 1911). Ann. Mag. Nat. Hist., ser. 8, 7: 591. Biteye, Dja River, Cameroon.

Taxonomy Originally described in the genus *Epimys*. Synonyms: *laticeps*, *schoutedeni*, *weileri*. Subspecies: none. The form *grandis*, described as a subspecies of *H. aeta*, is now considered to be a separate species. Chromosome number: $2n = 54$, $FN = 86$ (Robbins *et al.* 1980).

Description Small mouse with cinnamon-brown pelage and very long tail. Dorsal pelage cinnamon-brown; hairs dark grey at base, cinnamon-brown at tip. Some longer guard hairs present. Juvenile pelage black to grey-brown. Ventral pelage pure white in appearance; hairs dark at base, white at tip. Colour of dorsal pelage and ventral pelage clearly delineated on flanks and separated by buffy line. Rostrum short and blunt with long vibrissae. Eyes and ears large relative to head size. Hindfoot broad; Digit 5 rather long, ending near the middle of the terminal joint of Digit 4; Digit 1 ending beyond the base of Digit 2. On forefoot, Digit 5 about equal in length to Digit 2. Both fore- and hindfeet covered with short white hairs. Tail very long (ca. 145% of HB) with short hairs on the extreme end. Skull: supraorbital ridges very well developed (to a greater extent than other species in

the genus); frontal bone concave at interorbital constriction; anterior palatal foramina end anteriorly to or level with anterior end of M^1 ; upper incisors opisthodont. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

H. allenii/stella. Skull and body on average smaller and lighter in weight; ventral pelage not as pure white; supraorbital ridges on skull absent; tail naked.

H. parvus. Tail shorter; skull smaller.

Praomys spp. On average larger body size; tail usually relatively shorter; Digit 5 of hindfoot short; non-arboreal.

Heimyscus fumosus. Digit 5 on hindfoot short; pelage darker; tail shorter; eyes smaller.

Distribution Endemic to Africa. Rainforest BZ (mostly East Central and South Central Regions, and Gabon Subregion of West Central Region). Recorded from Cameroon, Equatorial Guinea (including Bioko I.), Gabon, S Central African Republic, Congo, DR Congo, W Uganda and NW Burundi (Dubost 1968, Eisentraut 1969a, Petter & Genest 1970, Musser & Carleton 1993, 2005, Malcolm & Ray 2000). Geographic limits uncertain (Musser & Carleton 1993, 2005).

Habitat In Dzanga-Sangha, Central African Republic, strong positive correlation between number of captures and density of understorey, with slightly higher preference for primary logging roads over unlogged forest (Malcolm & Ray 2000). In W Cameroon and Bioko I., occurs at medium to high altitudes (1200–2100 m) (Eisentraut 1969a).

Abundance Less common than other sympatric *Hylomyscus* spp. Comprised 9.5% of 1187 small mammals captured in traps set at three different heights in Dzanga-Sangha, Central African Republic (Malcolm & Ray 2000).

Adaptations Arboreal. Of the relatively common species of rodents, *H. aeta* was the only species to increase in abundance with increasing height of traps set above ground (Malcolm & Ray 2000).

Foraging and Food Predominantly vegetarian (Rosevear 1969). At Makokou, Gabon, consumed fruit (pulp and seeds) and insects,

Hylomyscus aeta

slightly favouring fruit (56.5%) rather than insects (43.5%) during dry season, but preferring insects (92%) instead of fruit (8%) during wet season (Genest-Villard 1980).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Litter-size: 2.8 (2–3, $n = 8$; Makokou, Gabon; Dubost 1968); and 2.8 (2–3, $n = 4$; Dzanga-Sangha, Central African Republic; J. C. Ray & J. R. Malcolm unpubl.).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Hylomyscus alleni ALLEN'S WOOD MOUSE (ALLEN'S HYLOMYSCUS)

Fr. Rat à poil doux d'Allen; Ger. Allens Waldmaus

Hylomyscus alleni (Waterhouse, 1838). Proc. Zool. Soc. Lond. 1837: 77 (publ. 1838). Fernando Poo (= Bioko I., Equatorial Guinea).

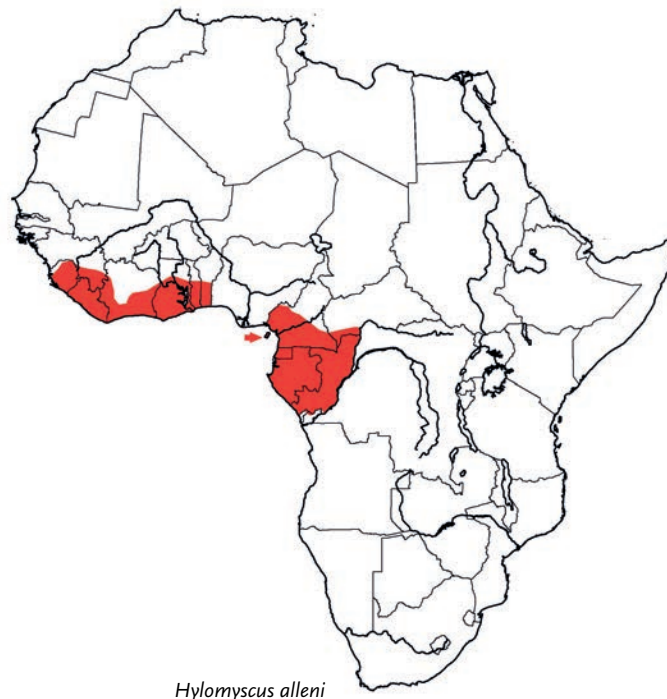

Taxonomy Originally described in the genus *Mus*. This species has had a history of taxonomic problems. Rosevear (1969) restricted *H. alleni* to Fernando Poo (= Bioko I.), but subsequent authors (e.g. Robbins *et al.* 1980) considered that it also occurs on the mainland of West Africa. The holotype was a juvenile specimen (Rosevear 1966, Robbins *et al.* 1980), which complicates definition of the species. *Hylomyscus alleni* is difficult to separate from *H. stella* using morphological characters, biometric analyses, or even cranial and dental features in some cases (Robbins *et al.* 1980, Iksandar *et al.* 1988). Synonyms: *canus*, *montis*, *simus*. Subspecies: none. Chromosome number: $2n = 46$, $FN = 68$ (Robbins *et al.* 1980).

Description Small climbing mouse with soft brownish pelage and very long tail. Dorsal pelage reddish-brown to greyish-brown; hairs grey at the base with brown-orange tips. Ventral pelage greyish-white; hairs grey on basal half, white on terminal half. Muzzle pointed. Eyes surrounded by faint dark ring. Ears large relative to head and covered by short fine red hairs that are barely detectable. Hindfoot narrow; Digit 1 of hindfoot reaches beyond the base of Digit 2; Digit 5 long, reaching as far as the middle of the terminal joint of Digit 4. On forefoot, Digit 5 about equal in length to Digit 2. Fore- and hindfeet covered with short white hairs. Tail very long (ca. 150% of HB), appears naked. Skull: no supraorbital ridges; incisors slightly proodont. No sexual dimorphism in size. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

H. aeta. Body size on average larger; pronounced supraorbital ridges on skull, no eye-ring, foot broader, base of tail with hairs.

Hylomyscus alleni

H. stella. Incisors orthodont.

H. parvus. Tail on average shorter; skull smaller.

Praomys spp. Body size on average larger; tail usually relatively shorter; Digit 5 of hindfoot shorter; terrestrial.

Heimyscus fumosus. Digit 5 on hindfoot shorter, pelage darker; tail almost always shorter; eyes smaller; terrestrial.

Distribution Endemic to Africa. Rainforest BZ (Western Region and parts of West Central Region [Eastern Nigeria and Gabon Subregions]). Recorded from two separate areas: (a) Sierra Leone, Guinea (e.g. Mt Nimba), Côte d'Ivoire, S Ghana and Togo; and (b) Cameroon, Equatorial Guinea (incl. Bioko I.), Gabon and SW Central African Republic (Musser & Carleton 1993, Grubb *et al.* 1998, Malcolm & Ray 2000). Not recorded from Benin and Nigeria.

Habitat Rainforest. Prefers micro-habitats characterized by relatively sparse understorey, dense canopy cover and an abundance of large trees (Adam 1977, Ray 1996). Abundant in primary and old secondary forests where shrubs and creepers plentiful, and in dense farm bush (Grubb *et al.* 1998). On Bioko I., none captured in montane forest in spite of intensive trapping (Eisenbraut 1969a). Found in drier parts of the bare forest floor (Sanderson 1940).

Abundance Often the commonest species in relatively undisturbed forests; present but less abundant in degraded forests characterized by dense understorey and fewer large trees (Adam 1977, Ray 1996). In SW Central African Republic comprised 54.1% of all captures ($n = 458$) from unlogged mixed-species forest, 70.0% from monodominant *Gilbertiodendron dewevrei* forest ($n = 406$), 31.5% along secondary logging roads ($n = 704$) and 79.5% along streams ($n = 200$) (Ray 1996). In S Côte d'Ivoire, most commonly trapped small mammal (e.g. 46.6% of 670 and 47.4% of 78 captures) in undisturbed forest habitats; less abundant in highly degraded forests (0% of 83 and 8.7% of 23 captures), swamp forests (8.9% of 191) and gallery forests (12.5% of 40) (Adam 1977). In Tai Forest, Côte d'Ivoire, represented 18.4% of captures in forest habitats and 6.1% in rice and groundnut fields (Dosso 1975b). In sacred groves (forested 'islands' surrounded by savanna or secondary growth) of S Ghana, represented 12.9% of 280 small mammals, and second in abundance after *Praomys tullbergi* (Decher 1997). Because these mice are primarily arboreal (see below), terrestrial trapping may not reflect true relative abundance.

Adaptations Nocturnal (Sanderson 1940, Jeffrey 1975). Arboreal (Sanderson 1940, Rosevear 1969), although known to spend some time on ground (Dosso 1975b, Jeffrey 1975, Malcolm & Ray 2000). Agile climber (Grubb *et al.* 1998); climbing ability is enhanced because the elongated Digit 5 is almost opposable and is used for gripping small twigs, and the long tail is used as a counterbalance while climbing. Nests in holes are constructed in trees, bananas or plantains (Grubb *et al.* 1998). More commonly trapped in understorey and upper strata than on the ground (Adam 1977, Malcolm & Ray 2000). In forest at Adiopodoumé, Côte d'Ivoire, represented only 18.1% of small mammals captured on the ground, but 73.8% at 0–2 m, 87.9% at 2–5 m and 80% at >5 m (Adam 1977; see also Malcolm & Ray 2000). In contrast, trapping on logging roads in Dzanga-Sangha, Central African Republic, revealed some evidence for greater proportional abundance on the ground than at other heights (Malcolm & Ray 2000).

Foraging and Food Predominantly vegetarian (Rosevear 1969). In Sierra Leone, diet included seeds, roots, stems and fruits, with some insects (Taylor 1984, in Grubb *et al.* 1998).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Reproductive activity in ♂♂ and ♀♀ occurred at all times of the year, but with peaks of activity during the wet season (Ray 1996). During the dry season, relatively few ♀♀ were reproductively active, lactating and/or gravid; testes of ♂♂ were at their smallest size and only a small proportion of ♂♂ had scrotal testes. Litter-size: 2.7 (1–4, $n = 9$; Dzanga-Sangha, Central African Republic; J. C. Ray & J. R. Malcolm unpubl.). Mean body weights in Dzanga-Sangha significantly lower in dry season than in wet season.

Predators, Parasites and Diseases Found in scats of small carnivores from Dzanga-Sangha, although at disproportionately lower frequency than expected from population numbers revealed by trapping (Ray 1998).

Conservation IUCN Category: Least Concern.

Close association with undisturbed forests, and general absence from secondary forests, means that deforestation and degradation of forests (e.g. by logging and clearance for agriculture) constitute potential threats.

***Hylomyscus carillus* ANGOLAN WOOD MOUSE (ANGOLAN HYLOMYSCUS)**

Fr. Rat à poil doux d'Angola; Ger. Angolische Waldmaus

Hylomyscus carillus (Thomas, 1904). Ann. Mag. Nat. Hist., ser. 7, 13: 418. Pungo Andongo, Angola. 1200 m.**Taxonomy** Originally described in the genus *Mus*. Sometimes considered to be related to *H. aeta* or *H. alleni*, but may be more closely related to *H. stella* (details in Musser & Carleton 2005). Definition of this species is uncertain: Crawford-Cabral (1998) lists it as the only species of *Hylomyscus* in Angola, but Musser & Carleton (2005) suggest that two other species (*H. denniae* and *H. stella*) may also occur there. Synonyms: none. Chromosome number: not known.**Description** Small very long-tailed climbing mouse; one of the larger species in the genus. Pelage soft, moderately dense, dorsal hairs ca. 8 mm. Dorsal pelage brown to rufous-brown; hairs dark grey at base, rufous, pale brown or black at tip. Grey colour of base may show on surface of pelage. Flanks slightly paler, sometimes more rufous. Ventral pelage whitish-grey; hairs dark grey on basal half, white on terminal half. Lips, cheeks, throat and chest white. Long dark vibrissae (up to 25 mm). Forelimbs short, white above; Digits

*Hylomyscus carillus*

2, 3, 4 and 5 long with short claws; Digit 1 reduced to tubercle, without claw. Hindlimbs slightly elongated, especially hindfoot. Hindfoot white above; Digit 1 short; Digits 2, 3, 4 and 5 long; all digits with claws. Tail very long (ca. 130% of HB), not bicoloured, appears naked but ringed with small scales; small tuft of hairs on tip. Skull with strong supraorbital ridges; incisor teeth orthodont. Nipples 1 + 2 = 6 or 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

H. stella. On average slightly smaller; supraorbital ridges small or absent; incisor teeth orthodont; ? allopatric.

H. aeta. Skull larger; supraorbital ridges well-developed; incisor teeth opisthodont; allopatric, possibly parapatric in SE DR Congo.

Distribution Endemic to Africa. Zambezan Woodland BZ (northern part). Recorded from W and C Angola; perhaps occurs in SE DR Congo (Crawford-Cabral 1998). Misonne (1974) gives a larger range, which includes Cameroon, Gabon, Congo, DR Congo, W Uganda, N Angola and Bioko I., but which probably includes specimens now allocated to *H. aeta* and *H. stella* (see also Musser & Carleton 2005). Limits uncertain.

Habitat Unknown; 'probably occurs throughout ... the more forested areas' (Hill & Carter 1941).

Abundance Uncertain. Known from only 12 localities (Crawford-Cabral 1998; but see also above).

Remarks One ♀ collected in Jun was pregnant with six embryos (label, BMNH). Three ♀♀ collected at Hanha in May were lactating (Hill & Carter 1941).

Conservation IUCN Category: Least Concern.

Hylomyscus denniae MONTANE WOOD MOUSE (MONTANE HYLOMYSCUS)

Fr. Rat à poil doux de montagne; Ger. Gebirgswaldmaus

Hylomyscus denniae (Thomas, 1906). Ann. Mag. Nat. Hist., ser. 7, 18: 144. Mubuku Valley, Rwenzori East, Uganda. 7000 ft (2130 m).

Taxonomy Originally described in the genus *Mus*. The definition of this species is unclear (Musser & Carleton 2005). Bishop (1979) listed three subspecies: the comparatively large *H. d. denniae* (from Mt Kenya and the Aberdare Ranges, Kenya), the smaller *H. d. vulcanorum* (from W Kenya and the Kigezi/Virunga Mts of SW Uganda and E DR Congo) and *H. d. anselli* (a new subspecies from Zambia and N Tanzania), although none of these are currently recognized. The species is morphologically close to *H. carillus*; specimens described as *H. carillus* from WC Angola (Hill & Carter 1941) are probably *H. denniae* (Musser & Carleton 2005). The form *endorobae*, assessed as close to *Praomys* (Van der Straeten & Robbins 1997), is considered a *Hylomyscus* by Musser & Carleton (2005).

Specimens from E DR Congo and Rwanda appear to be relatively large and to associate with *denniae*. Synonyms: *anselli*, *endorobae*, *vulcanorum*. Subspecies: none. Chromosome number: 2n = 48 (west of L. Kivu, DR Congo; det. J. Olert unpubl.).

Description One of the largest and darkest species in the genus. Pelage rather long (ca. 8–10 mm), soft and dense. Dorsal pelage dark brownish-grey, without rufous colouration as in some other species in the genus; hairs dark grey with brownish tip. Flanks similar to dorsum with tinge of rufous. Ventral pelage whitish-grey; hairs dark grey with white at tip. Head similar in colour to dorsum. Rufous-buff on cheek between eye and ear. Upper lips, chin and throat

whitish-grey (similar to ventral pelage). Vibrissae long, black. Large eyes, surrounded by narrow ring of black hairs. Upper surfaces of fore- and hindlimbs white. Upper surface of each digit of hindfeet with small tuft of white hairs. Tail very long (ca. 140% of HB), dark, ringed with small scales; appears naked but with many small dark bristles; hairs slightly longer at tip. Skull: small and delicate; frontal bone at interorbital constriction smooth; supraorbital ridges small; anterior palatal foramina long and wide, reaching to M^1 ; cheekteeth narrow, over 4 mm in length. Nipples: $2 + 2 = 8$.

Geographic Variation Bishop (1979) recognized three subspecies (now synonyms) on the basis of length of the anterior palatine foramina and ratio with the condylo-occipital length:

H. d. denniae: most of eastern Africa.

H. d. vulanorum: Virungu Volcanoes (DR Congo); Rwenzori Mts, Impenetrable Forest, Mt Elgon (Uganda) and Cherangani Hills (Kenya).

H. d. anselli: Tanzania and Zambia.

Similar Species

H. aeta. On average slightly smaller; sympatric only in E DR Congo.

H. stella. Smaller; frontal bone concave; sympatric only in E DR Congo.

Praomys delectorum. Slightly larger, with longer ears, shorter tail and longer hindfeet; not arboreal; sympatric only in Tanzania.

P. jacksoni. Larger in all respects except ear length; not arboreal; sympatric in Uganda, E DR Congo and N Zambia.

Distribution Endemic to Africa. Zambezian Woodland BZ, southern part of Somalia–Masai Bushland BZ and parts of the Eastern Rainforest–Savanna Mosaic. Recorded in several discrete areas: (a) Rwenzori Mts (DR Congo/Uganda), the Virunga Mts (DR Congo/Uganda/Rwanda) (Misonne 1963, Delany 1975, Verschuren *et al.*

1983), and west and east of L. Kivu (DR Congo/Rwanda/Burundi); (b) Mt Elgon (Uganda/Kenya), Cherangani Hills, Mt Kenya and Aberdare Ranges of Kenya; (c) Highland areas of Mt Kilimanjaro, Mt Meru and Ngorongoro Crater, South Pare Mts, Uzungwa Mts, Rungwe Mts and Ukinga in Tanzania (Bishop 1979, Kingdon 1974, Stanley *et al.* 1998a); (d) several localities in NE and N Zambia (Ansell 1978); and (e) WC Angola. The species is presumed to have had a wider and more continuous distribution in the past (Misonne 1969a).

Habitat In E DR Congo and Rwanda, lives in *Hagenia* forests, heath forests of *Erica arborea* and sub-alpine habitats with *Senecio* and *Lobelia*, from ca. 2000 m to ca. 4400 m. Occurs in most trapping sites within these habitats, e.g. recorded in 20 of 23 sites (F. Dieterlen unpubl.). On Mt Elgon, Uganda, found only in montane forest and bamboo (but not in heather, swamps or rocky habitats) (Clausnitzer & Kityo 2001). On South Pare Mts, Tanzania, occurs occasionally at 1100 m (Stanley *et al.* 1998a).

Abundance Mostly common, but abundance varies with habitat. Comprised 7–30% of small mammals in most habitats in E DR Congo and Rwanda (F. Dieterlen, unpubl.). Recorded as ‘extremely common’ in the Rwenzori Mts (Thomas & Wroughton 1910). In South Pare Mts, Tanzania, at 2000 m, recorded at two (of four) sites, and where caught comprised 11% ($n = 9$, 3 spp.) and 30% ($n = 33$, 6 spp.) of small rodents; in both instances, was the second most common species after *Praomys delectorum* (Stanley *et al.* 1998a).

Adaptations Arboreal and mostly nocturnal. Constructs nests in tree holes. The very long tail and short hindfeet appear to be adaptations for climbing among branches and vines.

Foraging and Food Omnivorous. Forages both on and above the ground. In E DR Congo, vegetable material is the principal food (remains in all 28 stomachs examined), but insects and other invertebrates are also eaten (remains in 10 of the 28 stomachs) (F. Dieterlen, unpubl.). In other localities, food varied slightly: mainly insects, but also fruits and starchy matter on the Virunga Mts (Verschuren *et al.* 1983), and invertebrates, seeds and fruit pulp on Mt Elgon, Uganda (Clausnitzer 2003).

Social and Reproductive Behaviour Individuals in captivity were peaceful and did not display agonistic behaviour towards conspecifics (F. Dieterlen unpubl.).

Reproduction and Population Structure Reproductive rate and embryo number varied seasonally near L. Kivu, E DR Congo (F. Dieterlen unpubl.). In the ‘dry’ season (Jul–Aug; rainfall 25–50 mm/month) and early wet season (Sep; ca. 150 mm/month) 80% of ♀♀ were pregnant or lactating ($n = 35$). During the wet season (Oct–May; rainfall ca. 150–210 mm/month), the reproductive rate decreased to 9% ($n = 34$) in Oct–Jan, but then increased to 47% ($n = 29$) in Feb–May. Embryo number: 4.55 (3–7, $n = 29$ ♀♀). Mean number of embryos was higher at the end of the dry season (Jul, Aug) and the beginning of the wet season (Sep) than at other times of the year. Testes length of adult reproductively active ♂♂ was 6–8 mm. Females mature when 22 g, and first pregnancies occur when 22–25 g; ♂♂ mature when 22 g and when testes are 5 mm in length (F. Dieterlen, unpubl.).

Hylomyscus denniae

Conservation IUCN Category: Least Concern.

Conservation of montane forests are necessary for the conservation of this species (Schlitter 1989).

Hylomyscus grandis LARGE WOOD MOUSE (MOUNT OKU HYLOMYSCUS)

Fr. Rat à poil doux grande; Ger. Grosse Waldmaus

Hylomyscus grandis Eisentraut, 1969. Z. Säugetierk. 34: 300. Oku Mts, West Cameroon. 2100 m.

Taxonomy Described as a subspecies of *H. aeta* by Eisentraut (1969a) and Musser & Carleton (1993). Raised to specific status by Hutterer *et al.* (1992). Synonyms: none. Chromosome number: unknown.

Description Small arboreal mouse; the largest species in the genus *Hylomyscus*. Pelage fine and soft; dorsal hairs ca. 10 mm on back. Dorsal pelage greyish-brown to bright cinnamon-brown; hairs medium grey, brownish at tip (some with black tip). Ventral pelage whitish-grey; hairs dark grey, white at tip. Ventral colour clearly delineated from colour of flanks. Head similar in colour to dorsal pelage. Nose, upper lips, chin, lower cheeks off-white or whitish-grey. Vibrissae long and black. Ears small, darkly pigmented, with slight covering of short dark brown or black hairs. Forefeet small, with sparse whitish hairs; five digits; Digit 1 reduced and without claw. Hindfeet relatively short, with sparse whitish hairs; five digits, all with claws. Tail very long (145% of HB), ringed with scales; appears naked but with very short black bristles; longer bristles at tip. Skull and molars larger than in *H. aeta*. Nipples 1 + 1 = 4.

Geographic Variation None recorded.

Similar Species

H. aeta. Mostly smaller in external dimensions, skull smaller and narrower; cheekteeth smaller; widespread including S Cameroon.

H. stella. Smaller on average in external dimensions; skull smaller and narrower; cheekteeth smaller; may occur in the same area.

Distribution Endemic to Africa. Recorded only from the region of Mt Oku in C Cameroon.

Habitat Montane forest at 2100 m.

Abundance Apparently rare; known only from four specimens.

Remarks Very long tail suggests a scansorial life-style. A pregnant ♀ collected on 22 Jan had 5–6 embryos (specimen in ZFMK).

Conservation IUCN Category: Critically Endangered.

***Hylomyscus parvus* LESSER WOOD MOUSE (LESSER HYLOMYSCUS)**

Fr. Rat à poil doux africain; Ger. Kleine Waldmaus

Hylomyscus parvus Brosset, Dubost and Heim de Balsac, 1965. Biologia Gabonica 1: 149. Belinga Mts, Gabon.

Taxonomy Synonyms: none. Chromosome number: $2n = 46$, $FN = 70$ (Robbins *et al.* 1980).

Description Very small climbing mouse with short round head and stout body; smallest species in the genus. Dorsal pelage chocolate-brown or dark brown; hairs dark grey at base, brown at tip. Paler on flanks. Ventral pelage brownish-white; hairs brown, some with white tip. No clear delineation between colour of dorsal and ventral pelage. Ears large, rounded, naked or with very short hairs. Limbs relatively long for a *Hylomyscus*. Forelimb with short white hairs; Digit 1 of forefoot very short, without claw; Digits 2–5 long, each with small claw. Hindfoot short; Digit 1 short. Tail very long (140–165% of HB), pale, sparsely covered with very short pale hairs. Juvenile pelage grey-brown to almost black, darker than in adults. Skull: small and delicate; incisor teeth orthodont or very slightly pro-odont; very slight supraorbital ridges; frontal bone slightly concave or obviously concave at supraorbital constriction; anterior palatal foramina long and wide, not reaching the level of the anterior edge of M^1 ; incisor and molar teeth narrow. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

Other *Hylomyscus* spp. On average larger; dorsal pelage paler.

Heimyscus fumosus. Digit 5 on hindfoot shorter; pelage softer and darker; tail relatively shorter; eyes smaller.

Pracomys spp. Overall size larger; hindfoot longer; Digit 5 of hindfoot shorter.

Distribution Endemic to Africa. Rainforest BZ (West Central Region [Eastern Nigeria and Gabon Subregions] and East Central Region). Recorded only from two localities in Gabon, one in Congo (Brosset *et al.* 1965), one in Central African Republic (Genest-Villard 1980), six in South Cameroon (Robbins *et al.* 1980, Dudu *et al.* 1989) and one in N DR Congo (Dudu *et al.* 1989). Probably more widespread within the central African rainforests than these records indicate.

Habitat Primary and secondary forest (Brosset *et al.* 1965, Dudu *et al.* 1989, J.-M. Duplantier unpubl.), but also abandoned fields in DR Congo (Dudu *et al.* 1989).

Abundance Uncommon or rare. Represented 3.1% of rodents trapped at Masako, DR Congo (Dudu *et al.* 1989) and 2.6% at Makokou, Gabon (Duplantier 1982). Much less common at Masako than sympatric *H. stella* (very numerous) and *H. aeta* (uncommon).

Adaptations Terrestrial, scansorial and arboreal (Robbins *et al.* 1980).

Foraging and Food In Central African Republic, diet (as assessed by stomach contents) is fruit and insects, and similar to that of *H. stella*. In captivity, eats pulp of fruits and seeds (Genest-Villard 1980).

Social and Reproductive Behaviour Sex ratio: 1 : 1 at Makokou, Gabon ($n = 16$) (J.-M. Duplantier unpubl.).

Reproduction and Population Structure Embryo number: 2.4 (2–3, $n = 5$; Gabon; Dubost 1968, J.-M. Duplantier unpubl.).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Hylomyscus stella STELLA WOOD MOUSE (STELLA HYLOMYSCUS)

Fr. Rat à poil doux de Stella; Ger. Stella-Waldmaus

Hylomyscus stella (Thomas, 1911). Ann. Mag. Nat. Hist., ser. 8, 7: 590. Ituri Forest, between Mawambi and Avakubi, E DR Congo.

Taxonomy Originally described in the genus *Epimys*. Closely related to *H. alleni*, and difficult to separate from this species. Robbins *et al.* (1980) united the species with *H. alleni* in the 'alleni-group' because both species have a concave frontal bone at the interorbital constriction, narrow incisors and narrow molars. See also *H. alleni*. Synonyms: *kaimosi*. Subspecies: none. Chromosome number shows polymorphism, according to locality: $2n = 46$, $FN = 70$ and $2n = 46$, $FN = 72$ (DR Congo; Matthey 1963a); $2n = 46$, $FN = 74$ (Central African Republic; Viegas-Péquignot *et al.* 1983); $2n = 48$, $FN = 86$, $aFN = 82$ (Burundi; Maddalena *et al.* 1989).

*Hylomyscus stella*.

Description A small beautiful climbing mouse with very long tail. Pelage soft. Dorsal pelage rufous-brown; hairs dark grey, rufous-brown or dark brown at tip. In juveniles, dorsal pelage darker grey, without rufous tinge. Ventral pelage greyish-white or silvery-white; hairs grey at base, whitish at tip. Colour of ventral pelage clearly delineated from dorsal pelage. Head small, similar in colour to back. Ears large, rounded, slightly pigmented; appear almost naked, but with very short hairs. Hindfeet short and broad; Digit 5 opposable. Upper side of fore- and hindfeet white, sometimes yellowish- to reddish-brown. Tail very long (ca. 150% of HB), dark, ringed with small scales, almost naked but with very short bristles. Skull: small and delicate; supraorbital ridges small or absent; frontal bone slightly concave at interorbital constriction, incisors orthodont; incisors and molar teeth narrow. Nipples: $2 + 2 = 8$.

Geographic Variation None except for karyotypic variation (see Taxonomy).

Similar Species

H. alleni. Very similar; incisors pro-odont; marginally sympatric.

H. grandis. On average larger; very restricted distribution in Cameroon.

H. parvus. On average smaller in all respects.

Promys jacksoni. On average larger; partly arboreal; sympatric in DR Congo.

*Hylomyscus stella*

Distribution Endemic to Africa. Rainforest BZ (West Central, East Central and South Central Regions). Recorded from W Nigeria, S Cameroon, Gabon, SW Central African Republic, Congo, DR Congo (including Rwenzori Mts and Virunga Mts), SW Uganda, Rwanda and Burundi. Isolated records in Gotel Mts on Nigeria–Cameroon border (Hutterer *et al.* 1992), Imatong Mts in S Sudan (F. Dieterlen unpubl.), Uganda (Delany 1975) and Kakamega Forest and other forest relicts in W Kenya (Bishop 1979). Altitudinal distribution from near sea level (e.g. W Nigeria) to at least 2250 m (Burundi, Rwenzori Mts). Geographic range uncertain due to morphological similarity with *H. alleni*.

Habitat Primarily arboreal and associated with tangles, shrubs and the lower storeys of forest. In Nigeria, found in tangled vegetation in abandoned farmlands, 'palm bush', secondary growth bordering paths and roads in forested areas, and in open areas of rainforest where shrubs and creepers form a dense growth (Happold 1987). In the Virunga–Rwenzori region recorded in forests at 800–2250 m, in dense and dark places in bamboo forests, and in other forest types (Verschuren *et al.* 1983). Delany (1975) caught many more individuals at 0.5–9.0 ft above the ground, mostly at 1.5–6 ft, than on the ground. In lowland rainforest (800–1700 m) in E DR Congo, preferred habitat was primary forest on hills (where comprised 25% of captured small mammals); less favoured habitats were ravines with streams (17%), secondary forest (20%) and cultivation (5%) (F. Dieterlen unpubl., Rahm 1970). Although mainly arboreal, descends to the ground to forage and hence (in some localities) caught in considerable numbers on the ground (Duplantier 1989);

in contrast, very few were caught at ground level in rainforest in Nigeria (Happold 1977).

Abundance Difficult to assess because of arboreal habits. At Makokou, NE Gabon (where caught on the ground), comprised 58% of small mammals (9 spp., $n = 549$), ranging from 55 to 72% depending on time of year (Duplantier 1989). (A second species of *Hylomyscus*, *H. parvus*, comprised only 0.5–2.5%.) Likewise, the most abundant species at two localities at Monts Doudou, SE Gabon, comprising 26% ($n = 675$; 10 spp.) and 39% ($n = 802$; 10 spp.) of small mammals during a 12-month period (Nicolas & Colyn 2003). In E DR Congo, the third most numerous species after *Hybomys univittatus* and *Praomys jacksoni* (Dieterlen 1985a). In W Nigeria, comprised 58% of arboreal species in a forest–farmland habitat (Happold 1974), but only 5.6% of small rodents in a mark-recapture study over three years in rainforest (Happold 1977).

Adaptations Primarily arboreal, but also terrestrial. Nocturnal. Very active and agile when climbing amongst creepers and shrubs. Holds on to narrow twigs using long opposable Digit 5 of hindfoot, and uses long tail for balance.

Foraging and Food Forages on branches and on the ground. Besides feeding on live insects (see below), forages in leaf litter for dead insects. In Central African Republic, diet in the dry season (as assessed by analysis of stomach contents) was 56% vegetable material (mainly fruits) and 44% insects (mainly termites, with some ants and beetles). In the wet season, diet changed to 8% vegetable material and 92% insects (Genest-Villard 1980). Feeding is selective: in captivity, individuals ate 35 species of fruits and rejected 21 species. Different parts of fruits are eaten depending on the species (and probably also on nutritive value and ease of consumption): fruit pulp (47%) and seeds (28%) are preferred foods, and nuts (12%), arils (7.5%) and nutshells (2.5%) are less preferred (Genest-Villard 1980). The small incisor teeth and small narrow molar teeth limit which species of fruit, and which parts of a fruit, can be masticated and ingested. In E DR Congo, wild-caught individuals ate insects less often (remains in only 16 of 61 stomachs); captive animals consumed 35 spp. of fruits (Rahm 1972, F. Dieterlen unpubl.).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Reproduction occurs throughout the year with peaks of activity during the wet

season. In W Nigeria, pregnant ♀♀ recorded in all months except Dec and Feb (long dry season) and Aug (little dry season) (Happold 1974). On a yearly basis, pregnancy rate was just over 50%. A similar pattern of reproduction recorded in Uganda (Delany 1971) and Sudan (F. Dieterlen unpubl.). In E DR Congo (Dieterlen 1985a, b) pregnancy rate was 80% ($n = 132$) during the main wet season (Nov–May), 8–25% during the dry season (Jun–Aug) and 40% during the early wet season (Sep–Oct) (Dieterlen 1985a, b). Gestation: ca. 29.5 days (Delany 1971) – rather long for a rodent of this size. Mean embryo number varies according to season. During the wet season (Nov–Apr), it averaged 3.71 (range 3.3 [Mar] to 4.5 [Nov]); during the dry season and early wet season (May–Oct), it averaged 3.07 (range 2.0 [Jun] to 3.5 [Oct]). Mean embryo number also varies by locality: 3.4 (Gabon; Dubost 1968), 3.21 (Uganda; Delany 1971), 2.9 (1–4; Nigeria; Happold 1974). Females become mature at 13–16 g (Happold 1974, Dieterlen 1985a, Duplantier 1989, Dudu 1991), and most first pregnancies occur when weight is 15–20 g. At birth, young are naked and blind, and weigh 1.2–1.8 g. Dark pigmentation visible on Day 6–9. Thin covering of hair dorsally and ventrally Day 9–14. Adult pelage Day 25–48. Weight 4–8 g on Day 20 and 9–12 g on Day 40 (Delany 1971).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

GENUS *Lamottemys*

Mount Oku Rat

Lamottemys Petter, 1986. Cimbabesia, Ser. A, 8: 98. Type species: *Lamottemys okuensis* F. Petter, 1986.

A monotypic genus found only on Mt Oku, Cameroon. The genus is characterized by medium size, uniformly dark brown pelage, and tail about equal in length to the head and body. Digit 5 of forefoot very short with nail (as in *Desmomys*) and not with claw (as in *Oenomys*). Skull shape similar to a young *Oenomys*, upper incisors with faint groove (as in *Desmomys* but unlike *Oenomys*), upper molars stephanodont

(frequent connections between cusps) as in *Oenomys* (Figure 71). The genus appears to be closely related to *Oenomys* (Dieterlen & Van der Straeten 1988, Musser & Carleton, 1993) rather than to *Desmomys* as suggested by Petter (1986). The single species is *Lamottemys okuensis*.

R. Hutterer

Lamottemys okuensis MOUNT OKU RAT (MOUNT OKU LAMOTTEMYS)

Fr. Rat du Mont Oku; Ger. Oku-Lamotte-Maus

Lamottemys okuensis Petter, 1986. Cimbebasia, Ser. A, 8: 98. Mt Oku, W Cameroon.*Lamottemys okuensis*.

Taxonomy Externally similar to *Oenomys* but with distinctive cranial characters (see Genus profile). Synonyms: none. Chromosome number: not known.

Description Small to medium-sized mouse, similar in colour to *Hybomys* spp. but without any dark mid-dorsal stripe. Pelage soft and shiny. Dorsal pelage dark blackish-brown tinged with russet-brown, speckled with yellowish-brown; hairs dark grey, with yellowish-brown subterminal band and black tip. Many long pure black guard hairs. No mid-dorsal dark stripe. Ventral pelage yellowish-grey, paler than dorsal pelage; hairs grey at base, yellowish at tip. Colour of dorsal pelage merges with colour of ventral pelage. Head similar in colour to dorsal pelage. Ears relatively large, darkly pigmented, with some short black or dark brown hairs. Forelimbs yellowish-brown with four digits; Digit 1 absent; Digit 5 reduced in size with nail (not claw). Hindlimbs yellowish-brown, five digits, each with claw. Tail long (ca. 100% of HB), black, ringed with scales, many very small black bristles. Skull: see genus profile. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Hybomys badius. Externally similar but with faint black dorsal stripe; Digit 5 of forefoot with claw.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Restricted to the Kilum-Ijim Forest of Mt Oku, an old volcano in North West Province, Cameroon; this forest is isolated and has an area of only 21 km² and a high level of endemism (Eisentraut 1968b).

Figure 71. Skull and mandible of *Lamottemys okuensis* (ZFMK 91232; after original photograph by R. Hutterer).*Lamottemys okuensis*.

Habitat Undisturbed montane forest, at 2100–3000 m, where there is a dense understorey of brush, thornbushes and herbaceous plants (Eisentraut 1982).

Abundance Appears to be rare or uncommon.

Remarks The characters and proportions of the body (in comparison with *Oenomys* and *Desmomys*) suggest that it is mainly terrestrial and herbivorous (O. Fülling pers. comm.). Litter-size perhaps small: one ♀ captured on 24 Jan during the dry season contained one embryo (Dieterlen & Van der Straeten 1988). Mongooses and genets occur in Oku forest (Maisels *et al.* 2001) and are likely predators. Like other rodents, this species is hunted for food by the local community (O. Fülling pers. comm.).

Conservation IUCN Category: Endangered.

GENUS *Lemniscomys*

Grass Mice

Lemniscomys Trouessart 1881. Bull. Soc. Etud. Scient. Angers 10: 124. Type species: *Mus barbarus* Linnaeus, 1766.

Lemniscomys macculus.

The genus *Lemniscomys* is endemic to Africa and contains 11 species (Table 35) that inhabit grassland habitats north of the Sahara in NW Africa (one species) and large areas of savanna south of the Sahara (ten species). Striped grass mice are easily recognized by the attractive longitudinal stripes on the back and sides of the body, a cryptic pattern that elegantly blends the mice with the colour of their grassland habitat. Compared with Africa's other striped grass mice, genus *Rhabdomys*, Digit 5 of the forefoot in species of *Lemniscomys* is vestigial. The periosteum investing the braincase of *Lemniscomys*, as well as certain other arvicanthine rodents (*Arvicanthis*, *Pelomys*, *Rhabdomys*), is densely pigmented with melanin granules, an adaptation that is believed to provide protection from deleterious levels of ultraviolet radiation in these predominantly diurnal small mammals (Hill 1942, Timm & Kermott 1982).

Species of *Lemniscomys* are small to medium in size. Pelage relatively short (hairs ca. 5–8 mm over middle rump), closely adpressed to the body; hairs stiff to slightly hispid in some forms, especially over the rump. Dorsal pelage is characterized by a dark mid-dorsal stripe, dusky to black, that extends from the middle crown to the rump. On either side of this stripe are white or pale buff longitudinal lateral stripes on a dark grey or brown background. Three general patterns are evident: (a) lateral stripes absent or faint (*griselda* species-group); (b) continuous lateral stripes not broken into spots (*barbarus* species-group); and (c) lateral stripes that are normally continuous near the mid-dorsal line but broken into lines of spots more laterally (*striatus* species-group). The number and width of the lateral stripes vary according to species and populations. Ventral pelage is white, cream, or buff and sharply delineated from colour of back, sometimes accented by a buffy or pale orange lateral line. Pinnae short and broadly rounded, covered with tawny to rufescent hairs. Tail longer than head and body (T ca. 110–120% of HB); moderately hairy, partially obscuring annulations; bicolouration weakly defined, dorsal hairs blackish and ventral hairs reddish. Forefoot appearing three-fingered; Digits 2–4 normally developed, Digit 5 nearly as small as Digit 1 and, like it, equipped with a nail instead of a claw. Hindfoot narrow, with Digits 1 and 5 of hindfoot very short, their claws reaching the metatarsal–phalangeal joint of Digits 2–4. Plantar surface of metatarsus and digits naked, tarsus hairy; modal number of plantar pads variable according to species-group, typically six in *striatus* group, five in *griselda* species-group (hypotheneal indistinct or absent) and four in *barbarus* species-group (thenar and hypotheneal minute or absent).

Skull is narrow, rostrum short, cranial profile evenly arched. Zygomatic arches parallel-sided, lateral flaring slight even in old animals; zygomatic plate broad but short, leading edge straight to weakly concave, dorsal notch deeply incised. Interorbital region constricted, dorsal edges convergent and marked by a low supraorbital bead and small shelf. Braincase elongate, temporal ridging weak; interparietal comparatively short and narrow. Anterior palatal foramina

Table 35. Species in the genus *Lemniscomys*. Arranged in order of number and pattern of lateral stripes.
(n. d. = no data.)

| Species | Lateral stripe pattern (species-group) | Lateral stripes on each flank | Colour of ventral pelage | |
|-----------------------|--|--|--------------------------|--|
| <i>L. barbarus</i> | Continuous stripes not broken into spots (<i>barbarus</i>) | 7–8; pale yellow | White | |
| <i>L. zebra</i> | Continuous stripes not broken into spots (<i>barbarus</i>) | 6–7; honey-coloured | White or cream | |
| <i>L. hoogstraali</i> | Continuous stripes not broken into spots (<i>barbarus</i>) | 5; wide, white, interspersed with four narrow slightly spotted; very dark background | White | |
| <i>L. bellieri</i> | Some stripes broken into spots (<i>striatus</i>) | 8; similar in colour to background; all spotted | White | |
| <i>L. macculus</i> | Some stripes broken into spots (<i>striatus</i>) | 6–8; pale; upper stripes spotted | White | |
| <i>L. mittendorfi</i> | Some stripes broken into spots (<i>striatus</i>) | 8; pale; upper stripes spotted on dark background, lower stripes continuous | Greyish | |
| <i>L. striatus</i> | Some stripes broken into spots (<i>striatus</i>) | 4; obvious upper stripes, spotted; irregular pattern of spots below, not always in lines | White | |
| <i>L. roseveari</i> | Faint and obscure (<i>griselda</i>) | None (or obscure spotting not in stripes) | White | |
| <i>L. linulus</i> | Faint or none (<i>griselda</i>) | None (or obscure pale spotting) | Pure white | |
| <i>L. griselda</i> | None (<i>griselda</i>) | None | White | |
| <i>L. rosalia</i> | None (<i>griselda</i>) | None | White or off-white | |

long (ca. 75–82% of diastema length), extending between the anterior roots of the first molars; foramina broader and bluntly pointed anteriorly, narrower and acute posteriorly. Optic foramen large, nearly the size of the anterior alar fissure. Carotid circulation lacking supraorbital branch (sphenofrontal foramen and squamosal-alisphenoid groove absent, stapedia foramen present). Alisphenoid strut absent and auditory bullae medium-sized. Molars low crowned, moderately broad, with blunt cusps. Third molars approximately two-thirds the size of the second molars. Cusps t1 and t3 of M¹, as well as t4 and t6, approximately equal in size; t3 of M² tiny but present; t9 present on M¹⁻², small and closely connected to t8; M¹⁻² lacking t7 and posteroloph.

Figure 72. Skull and mandible of *Lemniscomys zebra* (HC 1322).

Anteromedian and labial cusplets variably developed on m₁₋₂, small if present; posterolophid of m₁₋₂ small, absent in some forms. Molar root formula: $\frac{5}{5}, \frac{4-5}{4}, \frac{3}{3}$. Upper incisors opisthodont and short, without grooves, enamel surface pale to medium orange (Figure 72). Grass mice are typically common where grass cover is suitably dense for nests and runways. They are recorded from natural savanna grasslands and woodlands, agricultural fields, abandoned farms and many other habitats where there is abundant grass cover. They are terrestrial and never dig burrows. Unlike many other grassland rodents, they are largely diurnal or crepuscular, and hence may be seen scampering through grasses during the daytime. When disturbed, they run quickly along little paths into the densest nearby cover. Grass mice feed principally on grass stems and seeds and, to a lesser extent, insects. The distribution and abundance of grass mice is patchy. Some species are widespread, others have very restricted distributions. In favoured habitats they may attain high population densities, but in other places, they are not common. When environmental conditions are good, grass mice are fecund, and hence population numbers increase rapidly. Population numbers oscillate greatly, especially in areas where savanna grasses are burned; after fire, when the grasses begin to sprout, recolonization occurs from unburnt grasslands nearby.

Lemniscomys is closely related to a group of genera that Misonne (1969a) informally acknowledged as the ‘*Arvicanthis* Division’. Although Misonne (1969a) affiliated certain Asian genera within this Division, subsequent studies (Musser 1987a, Ducroz *et al.* 2001) have supported its recognition as a radiation of six genera indigenous to Africa (*Arvicanthis*, *Desmomys*, *Lemniscomys*, *Mydomys*, *Pelomys*, *Rhabdomys*), and have separated Misonne’s Asian genera from the *Arvicanthis* Division. Within this clade of six genera, gene-sequence analyses portray *Lemniscomys* as the most basal lineage (Ducroz *et al.* 2001). The monophyly of the genus itself is corroborated by both morphological and molecular data (Ellerman 1941, Misonne 1969a, Ducroz *et al.* 2001). Fossils are so far recorded only from middle to late Pleistocene sites in Morocco (as *L. barbarus*, Amani & Geraads 1993), East Africa (as *L. aff. striatus*, Wesselman 1984) and DR Congo (as *L. rosalia*; Avery 1995, 1996).

| | Mid-dorsal stripe | HB mean (mm) | GLS mean (mm) | Chromosome number | Notes |

| | Well defined | 121 | 31.0 | n. d. | Angola, Zambia |
| | Wide | 136 | 31.9 | 2n = 54, FN = 64 | Widespread in Zambezan Woodland BZ |

No subgenera have been recognized, but the 11 species of *Lemniscomys* are divisible into three species-groups based on the pattern of their dorsal markings (see above): *griselda* species-group (*L. griselda*, *L. linulus*, *L. rosalia* and *L. roseveari*); *barbarus* species-group (*L. barbarus*, *L. hoogstraali* and *L. zebra*); and *striatus* species-group (*L. bellieri*, *L. macculus*, *L. mittendorfi* and *L. striatus*). Although these pelage-defined associations receive some support from other morphological traits (Carleton & Van der Straeten 1997) and craniodental morphometry

(Van der Straeten 1980b, Van der Straeten & Verheyen 1980), their monophyletic stature and phylogeographic relationships invite research using other information sources. Chromosome number is variable according to species, ranging from 2n = 44 to 2n = 56 (Van der Straeten & Verheyen 1978a, Gautun *et al.* 1986, Filippucci *et al.* 1986).

Michael D. Carleton

Lemniscomys barbarus BARBARY GRASS MOUSE (BARBARY LEMNISCOMYS)

Fr. Souris rayé de Barbarie; Ger. Mehrstreifen-Grasmaus

Lemniscomys barbarus (Linnaeus, 1766). Syst. Nat., 12th edn., 1. Addenda. Barbaria (= Morocco).

Taxonomy Originally described in the genus *Mus*. Species-group: *barbarus*. Most authors in the past, e.g. Rosevear (1969), Misonne (1974) and Musser & Carleton (1993), included all striped grass mice within a single species, *L. barbarus*. However, recent study has shown that the name *barbarus* should be used only for the North African representatives of the *barbarus* species-group (Carleton & Van den Straeten 1997). The North African *L. barbarus* is geographically isolated from other populations of the species-group south of the Sahara (see maps). It is likely that northern (*L. barbarus*) and southern (*L. zebra*) populations of the species-group were contiguous in the past when the Sahara was more mesic than at present. Much less is known about this species than about *L. zebra*, the most northerly of the sub-Saharan species of the genus. Synonyms: *ifniensis*. Subspecies: none. Chromosome number: 2n = 54 (Algeria; Filippucci *et al.* 1986).

Description Medium-sized grass mouse with pale lateral stripes. Dorsal pelage buffy-brown, with narrow dark mid-dorsal stripe and six or seven unbroken ochre or pale yellow stripes on each flank. Ventral pelage white. Head narrow and pointed, similar in colour to dorsal pelage. Ears large and rounded, covered with short rufous

hairs. Tail long (115% of HB), sparsely haired, dark above, pale below. Forefoot has only three functional digits. Nipples 2 + 2 = 8.

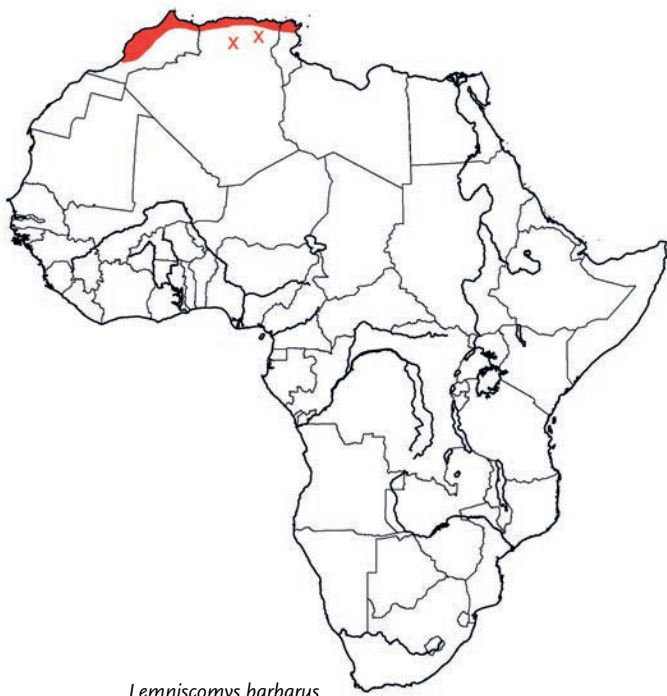

Geographic Variation None recorded.

Similar Species There are no other species of *Lemniscomys* in Africa north of the Sahara.

Distribution Endemic to Africa. Mediterranean Coastal BZ. Recorded from coastal regions (mostly north of the Atlas Mts) of Morocco, Algeria and Tunisia.

Habitat Bushes and grassy habitats along the coastal zone, where ground cover is dense. In Tunisia, also found in fields of lucerne, tomatoes and artichokes (Bernard 1969). Not recorded in the Haut Atlas or Saharan Atlas mountains (Aulagnier & Thévenot 1986, Kowalski & Rzebik-Kowalska 1991).

Abundance Mostly uncommon or rare even in preferred habitats, although densities may be high when conditions are suitable. In

Morocco, populations large in some years, very small in others (Brosset 1960).

Adaptations Terrestrial. Burrows are complex with 2–3 chambers, and are excavated under bushes and where food is available (e.g. in cultivated fields) (Lamine Cheniti & Sani 1989). Individuals in captivity were most active before and during sunset, and in the early morning after sunrise; a third lesser peak of activity occurred in the middle of the night. In cold weather, activity declined, especially at night (Lenkiewicz & Saint Girons 1964).

Foraging and Food Probably herbivorous (or omnivorous). These grass mice eat many sorts of food, often feeding close to the burrows;

may also feed on crops. Leaves of *Asphodelus microcarpus* (which have a high water content) found in burrows during dry season (Lamine Cheniti & Sani 1989).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Pregnant ♀♀ found in Tunisia in May, Jun and Sep; ♂♂ and ♀♀ not in reproductive condition during Nov–Jan. Adult ♂♂ reproductively active all year in Tunisia. Embryo number: 7.5 (3–11; Tunisia; Bernard 1969).

Predators, Parasites and Diseases Owls prey on striped grass mice in Algeria (Kowalski & Rzebik-Kowalska 1991).

Conservation IUCN Category: Least Concern.

These mice live in areas that have large human populations. Destruction of natural grassy habitats may be a threat to their survival.

Lemniscomys bellieri BELLIER'S GRASS MOUSE (BELLIER'S LEMNISCOMYS)

Fr. Souris rayée de Bellier; Ger. Belliers Grasmaus

Lemniscomys bellieri Van der Straeten, 1975. Rev. Zool. Afr. 89: 906. Ayeremou (= Lamto), Côte d'Ivoire.

Taxonomy Species-group: *striatus*. Related to *L. macculus*. Earlier studies included this species within *L. striatus*. Synonyms: none. Chromosome number: 2n = 56 (Van der Straeten 1975b).

Description Small grass mouse with well-defined black mid-dorsal stripe. Dorsal pelage yellowish-brown tending to grey on flanks; hairs grey at base. Eight lateral stripes on each flank broken into spots, pale buffy, and often not well differentiated from background colour. Only the spots of the 3rd, 4th and 5th stripes are arranged in well-defined lines. In extreme cases, the dorsal region has a close resemblance to that of *L. linulus*. Ventral pelage pure white, rarely washed with buff. Fore- and hindfeet washed with buff. Tail long (ca. 100% of HB), bicoloured, dark brown above, nearly white below. Nipples 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

L. linulus. Lateral stripes absent; may be sympatric.

L. striatus. Larger; lower lateral stripes broken into spots; sympatric.

L. macculus. Same body measurements but with different pattern of stripes; eastern Africa only.

L. zebra. All stripes continuous; paler; sympatric.

Distribution Endemic to Africa. Guinea Savanna BZ and Northern Rainforest–Savanna Mosaic. Recorded only west of the Dahomey Gap from Côte d'Ivoire and Ghana. One record from Guinea. May occur in Sierra Leone (Grubb *et al.* 1998). Probably more widely distributed than records indicate (Van der Straeten 1975a).

Habitat Grasslands, especially where *Isobertina doka* and *I. danielli* trees are common. In the Rainforest–Savanna Mosaic found in savanna

habitats, whereas *L. striatus* occurs closer to the forest edge (Van der Straeten 1975a).

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Lemniscomys griselda **GRISELDA'S GRASS MOUSE (GRISELDA'S LEMNISCOMYS)**

Fr. Souris rayée de Griselda; Ger. Griselda-Grasmaus

Lemniscomys griselda (Thomas, 1904). Ann. Mag. Nat. Hist., ser. 7, 13: 414. Muene Coshi, Angola.

Taxonomy Described as *Arvicanthis dorsalis griselda* (Thomas 1904c). Species-group: *griselda*. Formerly considered the nominate form of a polytypic species occurring in southern and eastern Africa. This species, *L. rosalia* and *L. roseveari* are morphometrically similar with considerable inter-species overlap in characters, and none have longitudinal lateral stripes. Van der Straeten (1980a) considered the nominate *griselda* to be a distinct species restricted to Angola, and separate from *L. rosalia* and *L. roseveari*. Ansell (1978) assigned specimens from NW Zambia to the nominate *L. griselda* and mentioned the possibility of intergradation with subspecies of *L. rosalia*. The *griselda* species-group (i.e. *L. griselda*, *L. linulus*, *L. rosalia* and *L. roseveari*) is in need of revision (Crawford-Cabral 1998, Musser & Carleton 2005). Synonyms: none. Chromosome number: not known.

Description Medium-sized grass mouse with coarse pelage and a single dark mid-dorsal stripe (similar to *L. rosalia*). Dorsal pelage pale grey-brown. Black mid-dorsal stripe extends along spine from neck to base of tail. Flanks slightly paler than dorsal pelage. No longitudinal lateral stripes on flanks. Ventral pelage white. Head with blunt nose and long vibrissae. Muzzle pale yellow. Ears medium-sized. Yellowish eye-ring present. Limbs medium-sized, same colour as flanks. Forefeet with three functional digits, Digits 1 and 5 greatly reduced. Hindfeet with three elongated digits, Digits 1 and 5 shorter. Tail long (ca. 100% of HB), dark with sparse short hairs.

Geographic Variation None recorded.

Similar Species

Lemniscomys rosalia. Very similar, no lateral stripes on flanks; greater suffusion of buff on dorsal pelage and flanks; allopatric and widespread.

L. roseveari. No lateral stripes; probably parapatric.

L. striatus. Well-defined lateral stripes on flanks.

Distribution Endemic to Africa. Zambezan Woodland BZ. Recorded from Angola and Zambia. Widespread on the Angolan plateau (Crawford-Cabral 1998), extending into NW Zambia (Ansell 1978).

Habitat No information.

Abundance Reported to be very common in Angola (Monard 1935). Considering the large number of localities from which museum specimens have been collected (Crawford-Cabral 1998), this species is probably not uncommon on the Angolan plateau.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Lemniscomys hoogstraali HOOGSTRAAL'S GRASS MOUSE (HOOGSTRAAL'S LEMNISCOMYS)

Fr. Souris rayée de Hoogstraal; Ger. Hoogstraals Grasmaus

Lemniscomys hoogstraali Dieterlen, 1991. Bonn. Zool. Beitr. 42: 11. 12 miles N of Niayok, Paloich, Upper Nile Province, Sudan.

Taxonomy Known only from a single old adult male specimen. Species-group: *barbarus*. Status of this species is uncertain because the single specimen is imperfect (Musser & Carleton 2005). Synonyms: none. Chromosome number: not known.

Description Small grass mouse, similar to but larger than *L. zebra*; one of the darkest of *Lemniscomys* spp. (together with *L. mittendorfi*). Mid-dorsal black stripe. Flanks very dark with five wide white unbroken lateral stripes on each flank, narrow anteriorly near head, wider posteriorly on rump. Four small narrow white stripes, often broken into small spots and streaks, on each flank in between the wide unbroken stripes. The wide white lateral stripes on the black background are extremely marked, giving a very 'zebra-like' effect (more so than in *L. barbarus* and *L. zebra*). Ventral pelage almost pure white, without any cinnamon or yellowish border between colour of dorsal pelage and ventral pelage. Ears rounded, covered with short rusty-brown hairs, and rusty-brown hairs at base. Fore- and hindfeet whitish. Tail long (ca. 100% of HB; tail tip missing), bicoloured, with short bristles, black above, pale below. Skull larger than in *L. zebra*; anterior palatal foramina ending anteriorly to M¹. Nipples: not known.

Geographic Variation None recorded.

Similar Species

Lemniscomys zebra. Smaller body and skull (especially HF), fewer narrower longitudinal stripes; yellowish border between dorsal and ventral pelage, fore- and hindfeet yellowish or cream.

L. striatus. Lateral stripes broken into spots and streaks.

Distribution Recorded only from the type locality, east of the Nile R. and north of Malakal, EC Sudan.

Habitat Forested grassland with *Acacia mellifera* and *Balanites aegyptiaca* trees.

Abundance Very rare. Only a single specimen was obtained amongst ca. 100 small rodents (mainly *Mastomys* sp., *Acomys cinereus* and *Arvicanthis niloticus*) collected near the type locality. Another single specimen of *L. zebra* was collected nearby.

Lemniscomys hoogstraali

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Lemniscomys linulus SENEGAL GRASS MOUSE (SENEGAL LEMNISCOMYS)

Fr. Souris rayée de Senegal; Ger. Senegal-Grasmaus

Lemniscomys linulus (Thomas, 1910). Ann. Mag. Nat. Hist., ser. 8, 6: 429. Gamon, French Gambia (= Senegal).

Taxonomy Originally described in the genus *Arvicanthis*. Species-group: *griselda*. Originally described as a species but Allen (1939) treated it as a subspecies of *L. griselda*. Re-instated as a valid species by Van der Straeten (1980b). Synonyms: none. Chromosome number: not known.

Description Small grass mouse. Dorsal pelage buffy-grey becoming more ochraceous posteriorly. Well-defined black mid-dorsal stripe. Many faint lateral stripes of very small pale spots, not well defined (and barely visible) in some individuals; hairs with pale tips where forming small spots. Spots obscure in museum specimens (so appearance is similar to *L. griselda*). Ventral pelage pure white with buff line separating colour of flanks and ventral pelage. Fore- and hindfeet with buff hairs. Tail long (ca. 105–110% of HB), dark above, ochraceous laterally and buff below. Nipples 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

L. striatus. Well-defined lateral stripes on flanks, mostly broken into spots.

L. zebra. Well-defined lateral stripes on flanks, not broken into spots.

Distribution Endemic to Africa. Guinea and Sudan Savanna BZs of West Africa west of the Dahomey Gap. Recorded from Côte d'Ivoire, Senegal and Mali (L. Granjon unpubl.). May have a more extensive distribution from Gambia to Ghana (Grubb *et al.* 1998).

Habitat Agricultural land, bush and grass (specimen labels) and dry woodland savanna (Bellier & Gautun 1967). Co-exists with *L. striatus* and *L. zebra* in some localities.

Abundance Rather common. In NE Côte d'Ivoire, five times as many specimens of this species were captured compared to other *Lemniscomys* (*L. zebra* and *L. striatus*) (Bellier & Gautun 1967).

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Lemniscomys macculus BUFFOON GRASS MOUSE (BUFFOON LEMNISCOMYS)

Fr. Souris rayée tachetée; Ger. Tüpfelgrasmaus

Lemniscomys macculus (Thomas & Wroughton, 1910). Trans. Zool. Soc. Lond. 19: 515. Mokia, SE Rwenzori, Uganda.

Taxonomy Originally described in the genus *Arvicanthis*. Species-group: *striatus*. Considered to be a valid species and not a small form of the larger *L. striatus* (Van de Straeten & Verheyen 1979a). Probably closely related to *L. bellieri*. Often confused with *L. striatus*, with which it is sympatric in Kenya and Ethiopia (Musser & Carleton 2005). Synonyms: *akka*. Subspecies: none. Chromosome number: $2n = 56$, $FN = 60$ (Ethiopia; Bulatova *et al.* 2002).

Description Small grass mouse, second smallest of all the grass mice, very similar morphologically to *L. striatus*. Dorsal pelage dark brown, mostly so dark that the mid-dorsal line is nearly inconspicuous. Seven (sometimes six or eight) pale (never white) longitudinal lateral stripes on each flank; upper stripes broken into irregular spots or streaks, lower stripes (from the 4th downwards) tend to be continuous. Ventral pelage white. Hindfeet small. Fore- and hindfeet white or whitish-yellow. Tail very long (ca. 110–120% of HB), bicoloured, upper surface brownish-black, lower surface paler. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species

L. striatus. Body and skull on average larger (HB: 116 [107–123] mm, HF: 25 [2–27] mm, GLS: 28.4 [26.1–30.9] mm); weight on average heavier (41 [31–48] g).

Distribution Endemic to Africa. Guinea Savanna BZ and Northern and Eastern Rainforest–Savanna Mosaic in eastern Africa.

*Lemniscomys macculus*

Recorded from NE DR Congo, Uganda, SE Sudan, N Kenya and SW Ethiopia. Possibly also occurs in Rwanda, Burundi and N Tanzania (E. Van der Straeten pers. comm.). Limits uncertain.

Habitat Dry river beds, open grasslands with *Acacia* and *Euphorbia candelabra* and, rarely, in dense grasslands (H. Rupp unpubl., Verheyen & Verschuren 1966). In SE Sudan, occurs in regions where annual rainfall is 800–1200 mm. Also occurs on rocky outcrops (Verheyen & Verschuren 1966). Unlike *L. striatus*, not found in cultivated areas.

Abundance Uncertain. In habitats in Uganda where *L. macculus* and *L. striatus* were sympatric (and sometimes syntopic), *L. macculus* was the least numerous of the two species (Verheyen & Verschuren 1966, Delany 1975).

Adaptations Terrestrial and partly diurnal. Constructs small underground burrows. Nests may be constructed on the surface of the ground, in burrows, or in natural holes, which are sometimes shared with the toad *Bufo regularis* (Verheyen & Verschuren 1966).

Foraging and Food Stomach contents consisted entirely of grasses (Verheyen & Verschuren 1966).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Pregnancies recorded in wet season in Sudan ($n = 5$ ♀♀). Embryo number: 6.0 (5–7). Pregnancies not recorded during dry season (H. Rupp unpubl.). Litter-size larger than in *L. striatus*, perhaps an adaptation to the drier environmental conditions and shorter period of reproduction.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

***Lemniscomys mittendorfi* MITTENDORF'S GRASS MOUSE (MITTENDORF'S LEMNISCOMYS)**

Fr. Souris rayée de Mittendorf (Souris rayée du Lac Oku); Ger. Mittendorfs Grasmaus

Lemniscomys mittendorfi Eisentraut, 1968. Bonn. Zool. Beitr. 19: 7. L. Oku, Cameroon.

Taxonomy Species-group *striatus*. Shows morphometric affinities with *L. macculus* and *L. bellieri* (Van der Straeten & Verheyen 1980). Synonyms: none. Chromosome number: $2n = 56$, $FN = 66-72$ (Fülling 1992).

Description Small striped grass mouse with a striking dark-brown coloured pelage. One of the darkest of *Lemniscomys* spp. (together with *L. hoogstraali*). Dorsal pelage dark brown, with a small black mid-dorsal stripe; flanks greyish. Eight pale-spotted lateral stripes; top three stripes with clearly visible spots, lower stripes tend to be continuous without spots. Ventral pelage grey; hairs grey at base, white on terminal half but tending to brownish-yellow on chest. Eye-ring and nasal region buff. Fore- and hindfeet buff, sparsely haired. Tail long (ca. 86% of HB), bicoloured, thickly clothed with short hairs in the middle section, black above, whitish-buff below. Nipples: not known.

Geographic Variation None recorded.

Similar Species

L. macculus. Similar body size; tail on average longer (and relatively longer); ventral pelage pure white; longitudinal stripes similar to *L. mittendorfi*; East Africa and NE DR Congo.

L. bellieri. Similar size; ventral pelage pure white; faint pattern of pale lateral stripes; west of Dahomey Gap.

L. striatus. Larger; less dark; does not occur on Mt Oku, although widespread in surrounding regions.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known only from the type locality in Cameroon.

Habitat Afroalpine grass savanna with bushes above the montane forest zone on Mt Oku (ca. 2300 m).

Abundance Rare; known from only ten specimens.

Remarks Apparently no other information available.

Conservation IUCN Category: Vulnerable.
Geographic distribution very restricted.

Key Reference Van der Straeten & Verheyen 1980.**Erik Van der Straeten*****Lemniscomys rosalia* SINGLE-STRIPED GRASS MOUSE (SINGLE-STRIPED LEMNISCOMYS)**

Fr. Rat rayée de Rosalie; Ger. Einsstreifen-Grasmaus

Lemniscomys rosalia (Thomas, 1904). Ann. Mag. Nat. Hist., ser. 7, 13: 414. Monda, Tanzania.

Taxonomy Originally described in the genus *Arvicanthis*. Species-group: *griselda*. Formerly known as *Lemniscomys griselda*, but now considered to be a different species, *L. rosalia* (Van der Straeten 1980a) and closely related to *L. griselda* and *L. roseveari*. See also *Lemniscomys griselda*. Synonyms: *calidior*, *dorsalis*, *fitzsimonsi*,

maculosus, *mearnsi*, *phaeotis*, *sabiensis*, *sabulatus*, *spinalis*, *zuluensis*. Subspecies: five recognized by Meester *et al.* (1986), but they are of dubious value and not recognized here. Chromosome number: $2n = 54$, $FN = 64$ (NE Tanzania; Fadda *et al.* 2001).

Description Medium-sized grass mouse with coarse pelage, without lateral stripes. Dorsal pelage variable shades of pale orange-brown grizzled with dark brown; dorsal hairs grey at base, orange-brown or brown at tip. Black mid-dorsal stripe extends from neck to base of tail. Colour of rump usually rich buffy. Flanks slightly paler than dorsal pelage. No lateral stripes on flanks. Ventral pelage white to off-white; hairs white. Head with blunt nose and long vibrissae. Muzzle same colour as dorsal pelage. Ears medium-sized, buffy. Yellowish-orange eye-ring often conspicuous. Limbs medium-sized, same colour as flanks. Forefeet with three functional digits; Digits 1 and 5 greatly reduced. Hindfeet with three elongated digits. Digits 1 and 5 shorter. Tail long (ca. 100% of HB), dark above, pale below. Nipples: $2 + 2 = 8$.

Geographic Variation Individuals from arid western regions of southern Africa are noticeably paler than individuals from the mesic east. This difference, however, appears to be clinal rather than discrete.

Similar Species

- L. griselda* and *L. roseveari*. Lateral stripes absent or very faint; allopatric.
- L. macculus*. Smaller; many lateral stripes; maybe parapatric in East Africa.
- L. striatus*. Many lateral stripes, some broken into spots; maybe parapatric in East Africa.
- L. zebra*. Many lateral stripes, all continuous (not broken into spots); maybe parapatric in East Africa.

Distribution Endemic to Africa. Zambezan Woodland BZ and southern part of Somalia–Masai Bushland BZ. Recorded from E and N South Africa, E Swaziland, Zimbabwe, Mozambique, Malawi, N Botswana, N Namibia (De Graaff 1981), S Angola (Crawford-Cabral 1998) and Zambia (Ansell 1978). A separate population occurs in Tanzania and S Kenya (Swynnerton & Hayman 1950).

Lemniscomys rosalia

Habitat Tolerates a wide range of savanna habitats, but tall, dense grass is essential. Vacates recently burnt areas (Korn 1981, Swanepoel 1981, Bowland & Perrin 1988) but may return after grass has recovered (Monadjem & Perrin 1997). Often occurs in agricultural landscapes, especially fallow fields. Not recorded from montane grasslands and forests (Monadjem 1999a).

Abundance Very varied; common to very common in suitable habitats, but often rare or absent in some parts of its range. In Swaziland, replaces *Mastomys natalensis* as the numerically dominant species in tall *Hyperthelia*–*Hyparrhenia* grasslands about one year after a fire. Density reaches 15/ha under natural conditions, but higher where supplementary food is available (Monadjem & Perrin 1997). In other parts of range, abundance is varied: e.g. in S Malawi comprised 1% ($n = 222$ small rodents; 9 spp.) in thicket-clump savanna during one year, and present in only six out of nine trapping periods (Happold & Happold 1991); in Mozambique, comprised 0% in Oct, Jan and Apr, and ca. 8% in Jul (Gliwicz 1985); and in Zimbabwe, 0% in miombo, mopane and thicket habitats during the course of one year (1992–93), although known to be present in small numbers in miombo and mopane woodland in a previous year during the cool dry season (Linzey & Kesner 1997a).

Adaptations Terrestrial and predominantly crepuscular (A. Monadjem unpubl.). Builds untidy nests of grass, which are placed on the ground, usually at the base of a clump of grass.

Foraging and Food Herbivorous tending toward granivorous. In Swaziland, diet was 85% vegetable material and 15% seeds ($n = 9$ stomachs; Swaziland; Monadjem 1997b).

Social and Reproductive Behaviour Home-ranges of individuals appear not to overlap. Individuals kept in captivity exhibit aggression towards each other (A. Monadjem unpubl.), suggesting that individuals may defend territories. In captivity, ♂♂ share a nest with a ♀ and assist with the care of the young.

Reproduction and Population Structure Reproduction confined to the wet season. In N KwaZulu–Natal, South Africa, ♀♀ reproductively active from Sep to Dec (Swanepoel 1972); juvenile recruitment mostly in Jan–Mar (Swaziland and South Africa). Mean litter-size: 6.1 (Swaziland; Monadjem 1998a) and 6.5 (6–7, $n = 4$; KwaZulu–Natal, South Africa; Taylor 1998). Litter-sizes from 2 to 11 recorded elsewhere (Skinner & Smithers 1990). Gestation (in captivity): ca. 24 days. Birth-weight: 2.6 g. Incisors erupt Day 6–8. Young weaned Day 20 (Scott & Meester 1988). Population numbers relatively stable between seasons, except after a fire when all individuals move out of the burnt area. Individuals return to former range about three months after the fire (Monadjem & Perrin 1997). Survival rates low, and few individuals live for more than a year.

Predators, Parasites and Diseases Preyed on by Black-shouldered Kites *Elanus caeruleus* (Mendelsohn 1982), and recorded from pellets of Barn Owls *Tyto alba* in Swaziland (M. Avery, in litt.).

Conservation IUCN Category: Least Concern.

This widespread and numerous species is unlikely to become threatened in the near future.

Lemniscomys roseveari ROSEVEAR'S GRASS MOUSE (ROSEVEAR'S LEMNISCOMYS)

Fr. Rat rayée de Rosevear; Ger. Rosevears Grasmaus

Lemniscomys roseveari Van der Straeten, 1980. Ann. Cape Prov. Mus. Nat. Hist. 13 (5): 55. Balovale (= Zambezi), Zambia. 1015 m.

Taxonomy Species-group: *griselda*. Closely related to *L. griselda* and *L. rosalia*. The status of this species is uncertain (Musser & Carleton 2005). See also *L. griselda*. Synonyms: none. Chromosome number: not known.

Description Medium-sized grass mouse with black mid-dorsal stripe and obscure pale lateral spots. Dorsal pelage brownish, tending to greyish anteriorly and yellow-ochre posteriorly; well-defined black mid-dorsal stripe from between the ears to rump. Flanks covered with small spots of pale-tipped buff or ochraceous-buff hairs, which are not clearly aggregated into longitudinal lines. Ventral pelage pure white, edged with a buff line. Ears, fore- and hindfeet yellow-ochre. Hindfoot longer in ♂ ♂ than in ♀ ♀. Tail long (ca. 110% of HB), dark above, ochraceous-orange or yellow-ochre laterally, white below. Upper incisors mostly with faint grooves. Nipples 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

L. rosalia. Less brownish; Angola.

L. griselda. Less brownish; southern Africa and Tanzania.

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded from two localities in Zambia: the type locality (Zambezi [= Balovale]) and Solwezi. Probably more widely distributed than present records indicate.

Habitat No information.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Lemniscomys roseveari

Lemniscomys striatus STRIATED GRASS MOUSE (STRIATED LEMNISCOMYS)

Fr. Rat rayée d'Afrique; Ger. Streifengrasmaus

Lemniscomys striatus (Linnaeus, 1758). Syst. Nat, 10th edn., 1: 62. 'India' (= Sierra Leone; see Allen 1939: 394).

Taxonomy Originally described in the genus *Mus*. Species-group: *striatus*. Synonyms: *ardens*, *dieterleni*, *fasciatus*, *luluae*, *lynsei*, *massaicus*, *micropus*, *orientalis*, *pulchella*, *pulcher*, *spermophilus*, *venustus*, *versustus*, *wroughtoni*. Subspecies: five are recognized by Van der Straeten & Verheyen (1980) (see Geographic Variation), but their status is uncertain. Recent analysis suggests that *massaicus* may be a valid species (with *dieterleni* as subspecies), and *lynsei* may also be a distinct species (E. Van der Straeten in litt.). Therefore, probably only two subspecies (*L. s. striatus* and *L. s. venustus*) are valid. Chromosome number: $2n = 44$ (Côte d'Ivoire; Van der Straeten & Verheyen 1978a).

Description Small grass mouse with black mid-dorsal stripe and lines of pale spots on back and flanks. Dorsal pelage brown often flecked with ochre. Black mid-dorsal stripe from neck to base of tail; flanks with four lines of pale yellow lateral stripes on each upper flank, each stripe broken into oblong or roundish spots. Additional spots not arranged in lines on lower flanks. Shape and clarity of spots very variable. Some individuals rufous or cinnamon on rump and base of tail. Ventral pelage white, clearly delineated from flanks. Head rather narrow and pointed, similar in colour to dorsal pelage; eye-ring and nasal region sometimes rufous. Ears large and rounded, covered with short rufous hairs. Forefoot with three functional toes. Tail long (ca. 125% of HB), dark above, pale below, sparsely haired. Nipples: $2 + 2 = 8$.

Geographic Variation Considerable variation in colour in different parts of range: individuals in and close to Rainforest BZ are darker with well-defined spots; individuals in savanna and drier habitats are paler with spots less well defined, some merging to form continuous lines. Size also varies in different parts of range. Five subspecies recognized by Van der Straeten & Verheyen (1980); subspecies distinguished by width of black mid-dorsal stripe, number and pattern of lateral stripes, and geographic location. May be distinguished by discriminate function analysis.

L. s. dieterleni: DR Congo.

L. s. striatus: West Africa (Sierra Leone to Cameroon).

L. s. lynsei: Jebel Marra, Sudan.

L. s. massaicus: Kenya, Uganda, Tanzania, N Malawi, Burundi, Rwanda, Sudan.

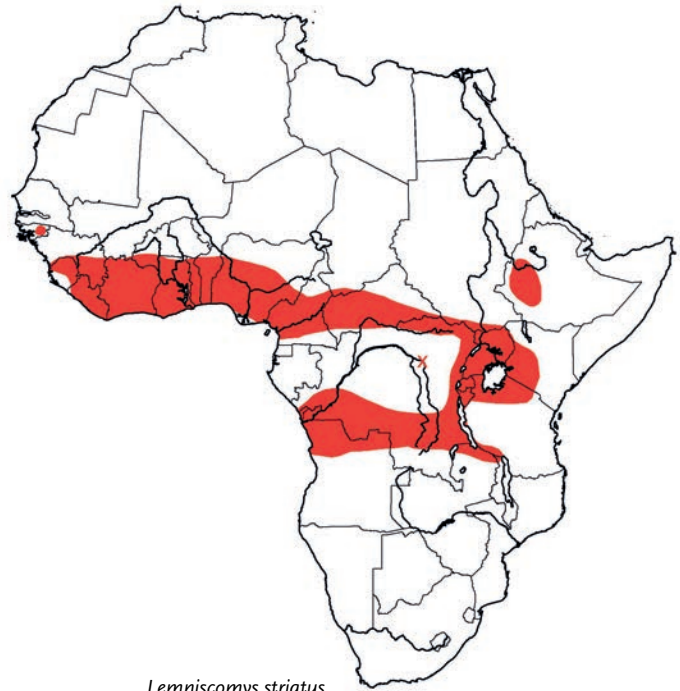

L. s. venustus: N Nigeria, N Benin (boundary Guinea and Sudan Savanna BZs); largest subspecies (HF: 26–33 mm; GLS: 28.4–34.6 mm).

Similar Species

L. zebra. Lateral stripes continuous (not broken into spots); usually paler; distribution further north but sympatric with *L. striatus* in southern parts of Guinea Savanna BZ.

L. bellieri. Upper lateral stripes broken into spots, lower stripes continuous; Côte d'Ivoire and Ghana.

L. linulus. Very well defined black mid-dorsal stripe; lateral stripes broken into spots, often obscure; Senegal and Côte d'Ivoire.

Lemniscomys striatus

L. macculus. On average smaller (HB: 99 (81–118) mm; 6–8 yellowish lateral stripes on each flank, upper stripes broken into irregular spots or streaks; partly sympatric in eastern Africa.

Distribution Endemic to Africa. The most widespread species in the genus. Guinea Savanna BZ, Rainforest–Savanna Mosaics, and northern parts of Zambezan Woodland BZ. Recorded from Sierra Leone to S Sudan and Uganda; W Kenya and N Tanzania; extreme N Malawi, NE Zambia; DR Congo and N Angola (including Cabinda). Also occurs in grassy patches in the Rainforest BZ, especially close to rainforest–savanna border. Isolated populations in C Sudan (Jebel Marra) and SW Ethiopia. Range expanding in Rainforest BZ due to human-induced environmental changes.

Habitat Dense cover of grasses or herbs in regions of moderate rainfall (1500–2000 mm/year). Found in woodland savannas, grassland savannas, rice fields, farmlands, abandoned fields and plantations (provided there is adequate grass cover). In Rainforest BZ, occurs only where there is natural or man-made grass cover, e.g. roadsides, farmlands, plantations. Not recorded from rainforest relicts in savanna. Rarely found in northern part of Guinea Savanna BZ or in Sudan Savanna BZ, where *L. zebra* occurs (see also below).

Abundance In optimal habitats, comprise the majority of small rodents, e.g. 48% (Foro-Foro, Côte d'Ivoire; Gautun 1975) and 47% (Queen Elizabeth National Park, Uganda; Cheeseman & Delany 1979). In other habitats, they are less numerous, e.g. 18% (Dabou, Côte d'Ivoire), 13% (grassbush, E DR Congo), 5% (*Pennisetum*, E DR

Congo) (Gautun 1975; Dieterlen 1967c). Many seemingly suitable habitats do not seem to contain any spotted grass mice.

The composition and structure of grasslands determine population numbers. In Queen Elizabeth N. P., Uganda, *L. striatus* occurs in all five major (unburnt) habitats. *Capparis* bush, *Themeda* and *Hyperrenia* grasslands contain higher numbers of grass mice than *Cymbopogon* and *Imperata* grasslands. In each of these habitats, grass mice form a varying proportion of the rodent fauna, from 40% in *Cymbopogon*, and *Themeda* to 27% in *Hyperrenia*. Population numbers fluctuate throughout the year in relation to reproductive activity, immigration and emigration (Neal 1970).

Burning of grasses at the beginning of the dry season also affects numbers. Immediately after burning, population numbers are reduced by 50–75% in all habitats. During the following months, numbers in burnt *Imperata* and *Themeda* grasslands gradually increase to their former levels whereas numbers decline in unburnt grasslands. In *Cymbopogon* grasslands – not a preferred habitat when unburnt – numbers increase dramatically (up to four-fold), because of rapid growth of good cover and immigration from less preferred habitats; after about ten months, numbers fall to pre-burn levels. All habitats that have been burnt contain higher populations of grass mice 3–10 months after burning than do unburnt habitats (Neal 1970, Delany 1972, Cheeseman & Delany 1979).

Seasonal changes in population parameters of grass mice in W Uganda are: density ranges from 2.6 to 16.1 individuals/ha; biomass (live trapping) from 233 to 467 g/ha in unburnt grasslands and from 374 to 1496 g/ha in burnt grasslands; net annual production from 1520 to 2804 g/ha/year (Cheeseman & Delany 1979).

Adaptations Terrestrial and crepuscular, with some activity at night prior to midnight. In unburnt grassland in Kivu, 62% of captures were during daytime (Dieterlen 1967a). Runways are made in grass and herbs; and nests are built of finely shredded grasses on the surface under dense cover. Body weight varies seasonally (usually 20% higher in wet season than dry season). Liver and body fat levels increase (especially in ♀♀) during the wet season (Field 1975) and decrease during the dry season when the fat is utilized. Increase in fat level is closely correlated with rainfall and with the quantity and quality of food. Spotted grass mice are adaptable: their populations exhibit seasonal changes in numbers (see above), they breed opportunistically, and move from one type of grassland to another as conditions dictate.

Foraging and Food Omnivorous or herbivorous. In Uganda, the most frequently eaten foods especially during the dry season were grass stems and inflorescences; seeds were eaten occasionally, but leaves were rarely eaten. During the wet season, insects (mainly termites) formed a major part of the diet (62–100% in some months). Insects formed an important source of protein during the breeding season (Field 1975). In coffee plantations in Central African Republic, from Aug to Oct, the diet was insects (up to 50%), seeds and fruits of several species (20%) and leaves (30%) (Genest-Villard 1980). In Kivu, stomachs contained 90% seeds and no insects (Dieterlen 1967a).

Social and Reproductive Behaviour Little information. Usually found singly or in pairs. Spotted grass mice have rapid flight reactions, and they appear to be 'nervous' when disturbed.

Reproduction and Population Structure Seasonal; closely related to pattern of rainfall. In Côte d'Ivoire (Gautun 1975), pregnancy rates vary seasonally: 70–100% during early wet season (Apr–Jun) and late wet season (Oct–Nov); 6–40% during mid wet season (Jul–Sep); and 0% during dry season (Dec–Mar). In Uganda (Neal 1977), where rainfall occurs in all months of the year, there are two peaks of rainfall: Mar–May and Aug–Dec. Pregnancies recorded in Apr–Jun and Sep–Dec, beginning from about one month after onset of rainfall peaks. Counts of placental scars after the two breeding seasons each year suggest 1–3 litters/♀ (one litter 16%; two litters 81%, three litters 3%; n = 37 ♀♀). Postpartum oestrus in ♀♀. Males reproductively active (increase in size of testes and seminal vesicles) in Apr–Jun and Sep–Dec. Timing and duration of reproduction related directly and indirectly to effects of rainfall (Neal 1977). Reproduction in burnt areas is slightly advanced compared to unburnt areas probably because of higher nutritive value of sprouting grass (Field 1975). Gestation: 22.6 ± 1.4 days. Mean embryo number in Côte d'Ivoire: 4.1 (first breeding season), 6.5 (second breeding season); in Uganda: 5.02 ± 0.18 (3–8), n = 58. Litter-size: 4.78 ± 0.17 (2–8 in Uganda). Embryo reabsorption: 4–50% (Côte d'Ivoire). Birth-weight: 1.6–1.8 g (in litter of five young). Body weight at maturity: 26 g (♀♀), 28 g (♂♂). Young sparsely haired at birth; pelage shows striped pattern as in adults.

Populations in Queen Elizabeth N. P., Uganda, contain individuals of most age groups in each month (age assessed on toothwear: classes I [young] to XIV [old]); proportion of each age-class changing in sequence each month due to effects of natality and mortality. Cohort born Sep–Dec forms Classes II–VI in Jan–Apr, and Classes V–VII (mature) in Apr–May. Some of these individuals are still alive in Nov (now age-classes XII–XIV, ca. 12 months old). Numbers of each cohort decline as members of the cohort increase in age. Second cohort (born Apr–Jul) form Classes II–VI in Jul–Nov and some individuals (age-class XII–XIV) are still alive in following Apr–May (Cheeseman & Delany 1979). Longevity in the wild rarely more than ca. 12 months.

Predators, Parasites and Diseases In Uganda, preyed upon by many species of birds of prey, mongooses *Herpestes ichneumon* and snakes.

Conservation IUCN Category: Least Concern.

This common, widespread and adaptable species is not threatened.

Lemniscomys zebra ZEBRA GRASS MOUSE (HEUGLIN'S LEMNISCOMYS)

Fr. Rat rayée zébrée; Ger. Zebragrasmaus

Lemniscomys zebra (Heuglin, 1864). Beit. Zool. Cent.-Afrika's Leopoldina 31: 10. Bahr el Ghazal, Sudan.

Taxonomy Originally described in the genus *Mus*. Species-group: *barbarus*. Previous authors, e.g. Rosevear (1969), Misonne (1974), Happold (1987) and Musser & Carleton (1993), considered *zebra* to be a synonym or subspecies of *L. barbarus*. However, Carlton & Van der Straeten (1997) showed that the striped grass mice immediately south of the Sahara should be considered as a separate species from the North African *L. barbarus*. Besides differences in the pattern of stripes, *L. zebra* has a smaller and less robust skull than *L. barbarus*. *Lemniscomys zebra*, as understood here, shows great variation in the colour and pattern of lateral stripes throughout its large range, and includes many forms, which, in the past, have had specific rank. Synonyms: *albolineatus*, *convictus*, *dunni*, *manteufeli*, *nigeriae*, *nubalis*, *olga*, *orientalis*, *oweni*, *spekei*. Subspecies: none. Chromosome number: $2n = 54$. FN = 58 (Niger; Dobigny *et al.* 2002b).

Description Small grass mouse with pale lateral stripes along flanks; the only species (with *L. barbarus*) with unbroken lateral stripes (i.e. not broken into spots or streaks). Dorsal pelage yellowish-brown or brown. Black mid-dorsal stripe from neck to base of tail. Six or seven honey-yellow or cream unbroken lateral stripes on each flank, each stripe as wide as the brownish 'background' colour. Ventral pelage white or cream. Head narrow and pointed, similar in colour to dorsal pelage. Ears large and rounded, covered with short pale rufous hairs. Tail long (ca. 110% of HB), sparsely haired, dark above, pale below. Forefoot has only three functional digits. Nipples: $2 + 2 = 8$.

Geographic Variation Considerable variation in colour in different parts of range, especially with respect to background colouration. Southern margins of Sahara: dorsal pelage yellowish-brown to pale brown with narrow dark mid-dorsal stripe and cream stripes on flanks. Guinea savanna: dorsal pelage medium brown to dark brown, well-defined black mid-dorsal stripe and cream stripes on flanks. S Sudan and East Africa: dorsal pelage dark brown or black, wide black mid-dorsal stripe, and thin cream stripes on flanks.

Similar Species

- L. barbarus*. Similar pattern of lateral stripes on back and flanks; on average larger; Morocco, Algeria and Tunisia only.
- L. striatus*. Pale lateral stripes broken into spots; moist savanna habitats including grassy areas in Rainforest BZ.
- L. bellieri*. Upper lateral stripes broken into spots, lower stripes continuous; Côte d'Ivoire and Ghana.
- L. linulus*. Well-defined black mid-dorsal stripe; spots and stripes often obscure; Senegal and Côte d'Ivoire.
- L. macculus*. 6–8 yellowish lateral stripes, upper stripes broken into irregular spots or streaks; partly sympatric in eastern Africa.

Distribution Endemic to Africa. Sahel, Sudan and Guinea BZs, and Northern and Eastern Rainforest–Savanna Mosaics; also southern part of Somalia–Masai BZ. Recorded from Senegal to C

*Lemniscomys zebra*

and S Sudan (including Jebel Marra [*dunni*]), Uganda, S Kenya and N Tanzania. Isolated populations in Niger (Damergou). Not recorded in Ethiopia although may occur close to the Sudan–Ethiopian border (Carleton & Van der Straeten 1997).

Habitat Dry grasslands and wooded grasslands in areas of low rainfall where there is good cover of grass, herbs or bushes. Prefers drier habitats than *L. striatus*. May be parapatric or sympatric with *L. striatus* in some habitats in West Africa and East Africa.

Abundance Mostly uncommon or rare, even in preferred habitats. Zebra Grass Mice formed 0.4% of all small rodents (9 spp.) at Foro-Foro, Côte d'Ivoire (Gautun & Petter 1972), and 12% in Karamoja, Uganda (Delany 1964a). Usually less abundant than *L. striatus*.

Adaptations Terrestrial, living and nesting on the surface. Zebra Grass Mice make runways through grass, and cut grass with their teeth for nests. When disturbed or frightened, they rush quickly under piles of dead grass or other dense vegetation where their striped pelage provides good camouflage. They are active mostly before and during sunset, and in the early morning after sunrise. In cold weather, activity declines especially at night. See also *L. barbarus*.

Foraging and Food No definite information, but probably herbivorous (or omnivorous) as for other species of *Lemniscomys*.

Social and Reproductive Behaviour Little information. Usually found singly or in pairs.

Reproduction and Population Structure Little information. Embryo number: 5 (n = 1; Uganda; Delany 1964a); 5 (n = 1; Togo; E. van der Straeten unpubl.).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Although uncommon, this widespread species does not appear to be threatened.

D. C. D. Happold & Fritz Dieterlen

GENUS *Malacomys* Swamp Rats

Malacomys Milne-Edwards, 1877. Bull. Sci. Soc. Philom. Paris, ser. 6, 12: 10. Type species: *Malacomys longipes* Milne-Edwards, 1877.

Malacomys longipes.

The genus *Malacomys* is endemic to Africa and contains three species, which live in rainforest habitats in West and central Africa. The genus is characterized by relatively large size, large naked ears, long vibrissae, elongated muzzle (more so than in most other small rodents) and long hindlimbs. Dorsal pelage is brown or very dark grey, soft and dense, and with a velvet-like texture. Ventral pelage is white or greyish-white, also short and velvet-like. Limbs are long, especially the hindfoot, which has loose-knit metatarsals that allow the digits to splay outwards. Hindfoot with five plantar pads (cf. *Praomys*). The skull is long and narrow, especially in the nasal region; posterior limit of anterior palatal foramina well anterior to M¹ (cf. *Praomys*), cheekteeth small and cuspidate; and t3 on M² small or absent (cf. *Praomys* where t3 is always present) (Figure 73). The common names – Long-footed Rats or Swamp Rats – refer to the relatively long hindfoot (longer than for other species of equivalent size, except for the semi-aquatic *Colomys*, *Deomys* and *Nilopegamys*) and the preference of these species for moist damp environments

Species in this genus are mostly terrestrial, and live in primary and secondary forest in the Rainforest BZ. They are usually (but not always) commonest near streams, in moist habitats on the lower slopes of valleys or in swampy areas of rainforests. When walking, especially on soft and water-logged soil, the body is lifted high off the ground

Figure 73. Skull and mandible of *Malacomys edwardsi* (HC 1354).

and the toes of the hindfeet are splayed to provide extra support. The diet is omnivorous, and includes slugs and earthworms. In body form and ecology (especially affinity for moist environments close to water), the genus shows similarities to *Colomys* and *Nilopegamys*. Abundance varies according to the species and location, contributing 7–23% of small terrestrial rodents in some localities.

The relationship of *Malacomys* to other genera is uncertain. Although previously considered to be distantly related to other genera (Misonne 1974), DNA hybridization shows a relationship to the *Praomys* group (i.e. *Praomys*, *Hylomyscus*, *Mastomys*, *Myomyscus* [= *Myomys*]) and to the *Mus* group (Chevret 1994). However, cladistic analysis suggests that the relationship with the *Praomys* group is not so close (Lecompte *et al.* 2002b). Two species formerly allocated to the genus *Malacomys* are currently in the genus *Praomys* (*P. lukolelae* and *P. verschurenii*), thus strongly suggesting a close relationship

between these two genera (see Rautenbach & Schlitter 1978, Van der Straeten & Verheyen 1979b, Musser & Carleton 1993, 2005). There is some evidence that *P. verschureni* and *P. lukolelae* may even represent a separate genus (E. van der Straeten pers. comm.).

The three species are distinguished by body size, length of hindfoot and geographic distribution.

D. C. D. Happold

***Malacomys cansdalei* CANSDALE'S SWAMP RAT (CANSDALE'S MALACOMYS)**

Fr. Rat palustre de Cansdale; Ger. Cansdales Sumpfratte

Malacomys cansdalei Ansell, 1958. Ann. Mag. Nat. Hist., ser. 13, 1: 342. Oda, Ghana.

Taxonomy This very long-footed rat from West Africa was described as a subspecies of *M. longipes* (Ansell 1958), and considered to be the western representative of *Malacomys longipes* of central Africa (Rautenbach & Schlitter 1978). Now considered to be a valid species (Van der Straeten & Verheyen 1979b, Grubb *et al.* 1998). Synonyms: *giganteus*. Subspecies: none. Chromosome number: not known.

Description Medium-sized long-footed rat, slimly built with large ears, long hindfeet and very long tail, similar in general dimensions to *M. edwardsi*. Pelage soft, dense and short, with a velvet-like texture. Dorsal pelage cinnamon; basal half of dorsal hairs medium grey, terminal half cinnamon; paler than in other species in the genus. Ventral pelage mostly white; ventral hairs white, pale grey at base; grey colouration visible on some parts of ventral pelage. Chin, chest and throat white. Head slender and muzzle elongated; vibrissae long; eyes large; ears elongated, rounded at tips, hairless, deeply pigmented, and very mobile. Tail very long (ca. 136% of HB), thin, almost hairless, dark above, pale below. Nipples 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species

M. edwardsi. HF shorter (34 mm or less); nipples 0 + 2 = 4; sympatric in Ghana and further west.

M. longipes. Very similar in size; east of Niger R. only; allopatric.

Praomys tullbergi. Smaller body size; HF and T shorter; sympatric and syntopic at some localities.

Distribution Endemic to Africa. Rainforest BZ (Western Region only). Recorded only from Ghana, Côte d'Ivoire and E Liberia. Sympatric with *M. edwardsi* throughout its range.

Habitat Rainforest habitats, especially close to streams and in valley bottoms, on lower slopes of the forests, sand banks at the edge of water, and on mud (Cole 1975). Not recorded from cultivated areas in Rainforest BZ. Prefers moister swampier habitats than *M. edwardsi*.

Abundance In Ghana, individuals comprised 7% of the terrestrial rodents in rainforests (Cole 1975, as *M. longipes*). Studies in Ghana and Côte d'Ivoire suggest this species is less abundant than *M. edwardsi*.

Remarks Terrestrial and nocturnal, probably with similar adaptations as other species of *Malacomys*. In Ghana, captive individuals paddled in water, and sometimes defecated in water. Omnivorous. Forages on lower slopes of rainforest, usually in a different part of the rainforest to *M. edwardsi* (Cole 1975). In Ghana,

Malacomys cansdalei

diet was mainly vegetable material, earthworms and slugs, and was similar in most respects to that of *M. edwardsi*. The holotype (collected in early February) contained four embryos (Ansell 1958).

Conservation IUCN Category: Least Concern.

Lives primarily in rainforest, and hence destruction of rainforest habitats will reduce the geographic range and population numbers.

Malacomys edwardsi EDWARDS'S SWAMP RAT (EDWARDS'S MALACOMYS)

Fr. Rat palustre de Edwards; Ger. Edwards Sumpfratte

Malacomys edwardsi Rochebrune, 1885. Bull. Sci. Soc. Philom. Paris, ser. 7, 9: 87.

Mellacoree River, Liberia (= Melikhoure River, Rep. of Guinea).

Taxonomy Previously considered to be a subspecies of *Malacomys longipes* (e.g. Allen 1939, Heim de Balsac & Lamotte 1958) and then a full species (Rosevear 1969, Misonne 1974). *Malacomys edwardsi* is clearly distinguishable from *M. longipes* by the smaller size of its skull and external measurements (Rautenbach & Schlitter 1978, Van der Straeten & Verheyen 1979b). See also *Malacomys longipes*. Synonyms: none. Chromosome number: $2n = 48$, $FN = 52$ (Matthey 1958, Van der Straeten & Verheyen 1979b).

Description Medium-sized long-footed rat, slimly built with large ears, long hindfeet and very long tail. Pelage soft, dense and short, with a velvet-like texture. Dorsal pelage rusty-brown to warm brown; hairs dark grey at base, warm brown at tip. Ventral pelage whitish-grey; hairs grey at base with white tips. Throat and chest whitish-grey. Head slender with elongated muzzle; vibrissae long. Eyes large. Ears elongated, rounded at tips, hairless and very mobile. Fore- and hindfeet whitish; hindfeet long with three long central toes. Tail very long (ca. 130% of HB), thin, almost hairless, dark above, pale below. Pelage of juveniles and young smoky-grey. Nipples: $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species

M. cansdalei. On average HB, T and HF larger; Ghana to E Liberia only.

M. longipes. On average HB, T and HF larger; E Nigeria and further eastwards.

Praomys tullbergi. Smaller size, HF shorter; E shorter; less pointed muzzle; syntopic.

Distribution Endemic to Africa. Rainforest BZ (Western Region and West Central Region [Western Nigerian Subregion]). Recorded from Guinea, Sierra Leone, Liberia, Côte d'Ivoire, Ghana and W Nigeria (west of the Niger R.). Occurs very rarely in forest patches in E Ghana (Decher 1997); not recorded in forest relics in Togo and Benin (Robbins & Van der Straeten 1996). Populations in W Nigeria (Western Central Region [Nigerian Subregion]) are geographically isolated from those of the Western Region.

Habitat Primary and secondary rainforest, especially where the soil is moist and damp (on slopes leading down to streams and along the edges of streams). Some individuals found in secondary bush, and in cocoa plantations and farmlands adjacent to rainforest (Jeffrey 1977). Does not occur in grasslands or cleared forest regions, nor in forestry plantations (e.g. teak) in Rainforest BZ.

Abundance Varies according to locality. In Sierra Leone, comprised 18% (second most numerous species after *Praomys tullbergi* [59%]) at one locality, and 22% (third most numerous species after *P. tullbergi* [30%] and *Hybomys trivirgatus* [28%]) at a second locality (Cross 1977). In Ghana, formed 23% (the second most numerous rodent

Malacomys edwardsi

after *P. tullbergi* [37%]) and 14% (third most numerous species after *P. tullbergi* [57%] and *H. trivirgatus* [20%]; Jeffrey 1977, Cole 1975). In W Nigeria, comprised 9% (second most numerous species after *P. tullbergi* [63%]) during a three-year mark-recapture study (Happold 1977).

Adaptations Terrestrial and nocturnal; may swim occasionally. Walks carefully on moist ground with only the toes of the long limbs touching the ground. Builds saucer-shaped nests of intact forest leaves, usually under logs and buttress roots of large trees. Tends to be inquisitive, sniffing with the nostrils and twisting the very large mobile ear pinnae from side to side when searching for food or sensing danger. The cheekteeth are small and the toothrow is short in relation to the length of the skull, indicating that only soft non-abrasive foods are eaten.

Foraging and Food Omnivorous. In Nigeria, food consisted of 40% vegetable material and 60% invertebrates, mostly insects ($n = 6$) (D. C. D. Happold unpubl.). Likewise, in Ghana, the food was ca. 50% vegetable material and 50% invertebrates, including earthworms, slugs and some grasshoppers, butterfly caterpillars and adult beetles (Cole 1975).

Social and Reproductive Behaviour Quiet and unaggressive when handled. In captivity, several may be kept together without showing agonistic behaviour.

Reproduction and Population Structure In W Nigeria, reproduction occurs during the dry season and early wet season (Nov–

Jul); juveniles enter the population during main part of wet season (Happold 1977). Litter-size: 2.5 (2–3).

Conservation IUCN Category: Least Concern.

Lives primarily in rainforest, and hence destruction of rainforest habitats will reduce their geographic range and population numbers.

Malacomys longipes LONG-FOOTED SWAMP RAT (COMMON MALACOMYS)

Fr. Rat palustre commun; Ger. Langfüssige Sumpfratte

Malacomys longipes Milne-Edwards, 1877. Bull. Sci. Soc. Philom. Paris, ser. 6, 12: 10.
Gaboon River, Gabon (= vicinity of Ogooué River, Gabon). (See Rautenbach and Schlitter 1978.)

Taxonomy Formerly considered to include *cansdalei* and *giganteus* from Côte d'Ivoire and Ghana (Bellier & Gautun 1968, Rosevear 1969, Rautenbach & Schlitter 1978). However, *giganteus* is a synonym of *M. cansdalei*, and *M. cansdalei* is considered now to be a valid species (Van der Straeten & Verheyen 1979b, Grubb *et al.* 1998). Consequently this species is now restricted geographically to E Nigeria and further eastwards. Synonyms: *australis*, *centralis*. Subspecies: three, validity uncertain. Chromosome number: 2n = 48 (Primus *et al.* 2006).

Description Large long-footed rat, slimly built with large ears, long hindfeet and very long tail; the largest species in the genus. Pelage soft, dense and short, with a velvet-like texture. Dorsal pelage medium to dark brown, usually without any tinge of cinnamon or russet; hairs dark grey, brown at tip. Ventral hairs greyish-white; hairs grey with white tips. Pelage colour varies between individuals and localities. Throat, chest and ventral pelage pale grey or milky-grey. Head slender with elongated muzzle; vibrissae long. Eyes large. Ears elongated, rounded at tips, hairless and very mobile. Fore- and hindfeet whitish; hindfeet long (longer than in *M. edwardsi*, but mostly shorter than in *M. cansdalei*) with three long central toes. Tail very long (ca. 120% HB), thin, almost hairless, dark above, pale below. Pelage of juveniles and subadults smoky-grey. Nipples: 1 + 2 = 6.

Geographic Variation Three subspecies are recognized by Rautenbach & Schlitter (1978), but the validity of these subspecies is uncertain and the differences in size may only reflect clinal variation.

M. l. longipes: E Nigeria, Cameroon, Gabon, Central African Republic, Congo and W DR Congo. Body and cranial measurements mostly within the lower to medium size range for the species.

M. l. centralis: NE and E DR Congo, Uganda, Burundi and NE Angola. Body and cranial measurements mostly at the upper size range for the species.

M. l. australis: Extreme NW Zambia. Similar to *M. l. centralis*, but geographically remote; some individuals have unique white triangular patch on ventral pelage (base of triangle between forelimbs, apex on abdomen).

Similar Species

M. edwardsi. Similar size, HF shorter; W Nigeria and further westwards; allopatric.

M. cansdalei. On average smaller; Ghana to E Liberia; allopatric.

Colomys goslingi. On average smaller in all external measurements; ventral pelage pure white; sympatric.

Praomys verschurenii. Smaller, shorter HF and T; sympatric with restricted distribution.

Deomys ferrugineus. Ventral pelage pure white, rich red-brown coarse-textured pelage, hindfeet on average shorter, and ears oval.

Distribution Endemic to Africa. West Central, East Central and South Central Regions of Rainforest BZ. Recorded from SE Nigeria, Cameroon, Gabon, Equatorial Guinea (Rio Muni and Bioko I.),

Malacomys longipes

Malacomys longipes.

Central African Republic, Congo, DR Congo, W Rwanda, W Uganda (Ankole) and NE Angola. Outlying populations occur in C Uganda (near Entebbe), S Sudan (near Yei) and NW Zambia. The distribution of *M. longipes* does not overlap with *M. edwardsi* and *M. cansdalei* (its ecological equivalents in West Africa).

Habitat Rainforest habitats especially moist areas close to streams (Rahm 1966); also found in some swampy habitats, in oil palm plantations and secondary forest. Occurs up to 1000 m on Mt Cameroon and the Rwenzori Mts in gallery forests, but not in bamboo or *Hagenia* forests (Rahm 1967). Rarely found in cultivated habitats (Rahm 1966). In Dzanga-Sangha, Central African Republic, exhibited extreme habitat specialization: relatively common in stream beds, but rare in upland forest habitats (Ray 1996). Rosevear (1969) and Sanderson (1940) also report a strong association of this species with water.

Abundance Varied, but not uncommon in some localities. Comprised 3–24% of the population of terrestrial small rodents in rainforest habitats (e.g. 3% in Mayanga Forest, Uganda; 20% near streams in E DR Congo and 24% in Kalinzu Forest, Uganda [Delany 1964a, Rahm 1972]). In Dzanga-Sangha, Central African Republic, it was the second most abundant terrestrial small rodent captured in stream beds (14.5%, $n = 200$; Ray 1996).

Adaptations Similar in most respects to *M. edwardsi*. May be more aquatic than *M. edwardsi* because favours moister habitats; probably spends a considerable amount of time in small water-courses in rainforest; likes to immerse body in water (Delany 1975). During daytime, rests in holes and crevices along river banks (Rahm 1966). One study found an individual in vines 2 m above a stream – an unusual observation because the feet are not adapted for climbing.

Foraging and Food Omnivorous. In E DR Congo, analysis of stomach contents indicated that 64% of individuals had fed only on vegetable material and 36% had fed on vegetable and insect material ($n = 55$). Other studies demonstrated relatively high percentage of soft invertebrates in stomachs, such as snails, slugs and earthworms (Genest-Villard 1980, Duplantier 1982, Struhsaker 1997).

Social and Reproductive Behaviour No information; probably similar to *M. edwardsi*.

Reproduction and Population Structure In E DR Congo, pregnancies recorded in Jan, Mar, May, Jul, Sep and Dec; monthly pregnancy rate ranged from 20% to 100% (Rahm 1970). Embryo number varies slightly according to locality: Cameroon: 2.5 (1–4, $n = 12$; Dubost 1968); E DR Congo: 3 (1–5, $n = 27$; Rahm 1970); Central African Republic: 2.3 (2–3, $n = 4$; J. C. Ray unpubl.).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Lives primarily in rainforest, and hence destruction of rainforest habitats reduces the geographic range and population numbers.

D. C. D. Happold

GENUS *Mastomys*
Multimammate Mice

Mastomys Thomas, 1915. Ann. Mag. Nat. Hist., ser. 8, 16: 477. Type species: *Mus coucha* Smith, 1834.

Mastomys natalensis.

The genus *Mastomys* is endemic to Africa and currently contains eight species (Table 36). It is widespread in Africa south of the Sahara with a relic population of one species in Morocco. Species of the genus live mainly in grasslands, wooded savanna, cultivated areas and human dwellings or stores. They also occur in human settlements in the Rainforest BZ, but are not known from deserts.

Species in the genus are small in size with soft pelage, darkish-brown dorsally and greyish ventrally. The head is slender with an elongated muzzle and long vibrissae. Eyes are large, and ears are elongated, rounded at tips, hairless and very mobile. Tail is about the length of HB or somewhat shorter, with small scales and short fine hairs between the scales. One of the most obvious characters is the two rows of nipples, each with 8–12 nipples, arranged almost contiguously from axilla to inguinal region (hence the vernacular name of ‘Multimammate Mice’). The skull typically has the anterior palatal foramina reaching well posteriorly to between the cheekteeth often as far as the median root of M¹; t3 is present on M¹ but smaller than t1, which is placed quite far to the rear; the palatine bone never extends forward beyond the front of M²; and the mesopterygoid fossa is very narrow at the margin of the palatine bone, generally less than 1 mm (sometimes larger in *M. kollmannspergeri*) (Figure 74).

Most species have large litters, and are able to breed very rapidly when conditions are favourable. When this happens it can lead to a

Table 36. Species in the genus *Mastomys*. Arranged in order of increasing mean head and body length.

Figure 74. Skull and mandible of *Mastomys erythroleucus* (HC 1659).

‘population explosion’, but when conditions deteriorate population numbers decline very rapidly. Several species and populations display such irregular population explosions. Multimammate mice are among the most adaptable of African mice, are capable of surviving in a wide range of environmental conditions, and are often the most numerous

mice in savanna habitats and agricultural fields. Multimammate mice are common pest rodents in agricultural fields and pest stores. They are important, also, because they are natural hosts of pathogens that cause sickness in humans.

Mastomys has often been listed as a subgenus in the genus *Praomys*, but it is now well accepted as a separate genus. Very few species of *Mastomys* can be recognized by size or colour alone, and most are very difficult to distinguish on external morphology or on skull measurements. Definite identification is possible only by karyological analysis or molecular methods. Musser & Carleton (1993, 2005) recognized eight species, but only five species (*M. coucha*, *M. erythroleucus*, *M. natalensis*, *M. pernanus*, *M. shortridgei*) are common to both studies. Additional species in Musser & Carleton (2005) are *M. awashensis* and *M. huberti* (species shown to be karyotypically different to other named forms), as well as *M. kollmannspergeri* (originally described as a subspecies of *M. natalensis*, but now recognized as a separate species with *verheyeni* as a junior synonym). Two species listed in Musser & Carleton (1993) have been reallocated: *Mastomys angolensis* is now provisionally placed in the genus *Myomyscus*, and *Mastomys hildebrandtii* is provisionally placed as a synonym of *M. natalensis*, while most specimens earlier classified as *M. hildebrandtii* are now placed in *M. huberti* (see Musser & Carleton 2005 for further comment). Specimens from widespread regions in Africa have been attributed to *M. natalensis*, but this is probably a species complex; likewise *M. erythroleucus* was recently recognized as a species complex. The genus requires careful systematic revision.

***Mastomys awashensis* AWASH MULTIMAMMATE MOUSE (AWASH MASTOMYS)**

Fr. Souris à mamelles multiples d'Awash; Ger. Awash-Vielzitzenmaus

Mastomys awashensis Lavrenchenko, Likhnova & Baskevich 1998. Z. Saugetierk. 63: 44.

Banks of the Awash River near Koka L., Ethiopia (ca. 08° 23' N, 39° 09' E).

Taxonomy Distinguished from other species of *Mastomys* in Ethiopia by multivariate craniometry, phallic morphology, spermatozoan structure, allozymes and chromosome characters. Synonyms: none. Chromosome number: $2n = 32$ (as in syntopic *M. natalensis* but with different C-banding).

Description Medium-sized grey mouse similar in size to *M. erythroleucus* but with relatively shorter tail bearing smaller scales. Dorsal pelage blackish, with greyish-rufous flanks. Ventral pelage greyish. Colour of dorsal and ventral pelage clearly delineated. Head blackish, with yellowish-rufous cheeks. Upper parts of fore- and hindfeet whitish, claws pale. Tail long (ca. 103% of HB), scaly. Skull typical of *Mastomys*, straight and strongly rounded dorsal edge of anterior margin of zygomatic plate, narrow mesopterygoid fossa, anterior palatine foramina extending to middle of M^1 ; palatine bone reaching no further forward than the middle of M^2 . Externally similar to sympatric *M. erythroleucus* and *M. natalensis*. Nipples: not known.

Geographic Variation None recorded.

*Mastomys awashensis***Similar Species**

M. erythroleucus. Slightly larger mean HB and T; ventral pelage cream; widespread distribution; common; $2n = 38$.

M. natalensis. Smaller mean HB and T; ventral pelage dark grey; widespread distribution; common; $2n = 32$.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ of Ethiopia. Recorded from only two localities: eastern bank of Koka L. and Awash N. P. Geographic limits uncertain, but probably more extensive than known at present. A further specimen from Zway (08° 00' N, 38° 48' E) may also represent this species (M. Corti unpubl.).

Habitat *Acacia–Commiphora* thornbush with high grass, and adjacent agricultural lands. Absent from buildings in human settlements.

Abundance Rare; known only from ten specimens.

Remarks Apparently no other information available.

Conservation IUCN Category: Vulnerable.

This species has a very limited geographic range and non-commensal life-style; there is progressive destruction of its habitat by agricultural development.

***Mastomys coucha* SOUTHERN AFRICAN MULTIMAMMATE MOUSE (SOUTHERN AFRICAN MASTOMYS)**

Fr. Souris à mamelles multiples du sud; Ger. Südliches Vielzitzenmaus

Mastomys coucha (Smith, 1834). Rept. Exped. Exploring Central Africa, p. 43.

Northern Cape Province, between Orange River and Tropic of Capricorn, South Africa. (Type locality fixed as Kuruman.)

Taxonomy Originally described in the genus *Mus*. Traditionally considered to be conspecific with *M. natalensis* but now known to be a valid species on the basis of its karyology and a 'faster' haemoglobin in electrophoresis. Good biological information about *M. coucha* is rather sparse because many studies were carried out in areas where it is sympatric with *M. natalensis* and karyological confirmation of the studied specimens is not available. Both the wild form and a chamois-coloured pink-eyed laboratory strain are used in medical research, sometimes still misnamed as *M. natalensis* (Kruppa *et al.* 1990). Synonyms: *bradfieldi*, *breyeri*, *limpopoensis*, *marikquensis*, *sicalis*, *silaceus*, *socialis*. Subspecies: none. Chromosome number: $2n = 36$, $FN = 54$.

Description Small grey mouse. Dorsal pelage darkish-grey (young) to rusty-brownish (old adults). Ventral pelage dark grey; hairs with paler tip. Fore- and hindfeet whitish. Tail long (ca. 100% of HB), dark above and below. Skull distinguishable from *M. natalensis* by multivariate techniques only, but with considerable misclassification (Dippenaar *et al.* 1993, Lecompte *et al.* 2002b). Spermatozoa and genital morphology slightly different from other species of *Mastomys* (Gordon & Watson 1986, Lavrenchenko & Baskevich 1996). Nipples: 12 (equally spaced from axilla to inguinal region) = 24.

Geographic Variation None recorded.

Similar Species

M. natalensis. Slightly larger mean HB and T; ventral pelage dark grey; broadly sympatric with *M. coucha* in southern Africa; common; $2n = 32$.

Distribution Endemic to Africa. Zambezian Woodland BZ and Highveld BZ. Recorded from S and W Zimbabwe, C Namibia and S Africa in areas receiving <800 mm annual rainfall. Partly overlaps with *M. natalensis*, and hence the identification of species in many earlier studies is uncertain. *Mastomys coucha* has a preference for higher altitude/relatively drier parts of South Africa, while *M. natalensis* prefers low altitude/high rainfall regions (Venturi *et al.* 2003). *Mastomys coucha* is currently thought to be the only *Mastomys* present in Free State, South Africa, meaning that a number of studies on biology there can now be ascribed to this species (N. Avenant unpubl.).

Habitat Grassland, woodland savanna, fields and human dwellings. Very common at disturbed sites. Due to the association of this species with such habitats, it can be used as an indicator species for the level of disturbance in, for example, nature reserves (Avenant 2000, 2002).

Abundance Common, particularly in disturbed habitats.

*Mastomys coucha*

Adaptations Probably similar to other species in the genus, but tolerates drier conditions than *M. natalensis*.

Foraging and Food Terrestrial and nocturnal. No specific information available but probably similar to *M. natalensis*.

Social and Reproductive Behaviour No information, but probably similar to *M. natalensis*.

Reproduction and Population Structure Reproduction is seasonal with a break in the dry winter months (Coetzee 1965), but other studies suggest that breeding continues throughout the year (Avenant 1996). Maturation is stimulated by chemicals present in germinating grasses (Linn 1991). Mean litter-size: ca. 8–10. Gestation: 21–22 days. Interval between litters 33 days (average). At birth, young altricial. Eyes open Day 15. Weaning Day 21 (Meester 1960). Sex ratio around 1 : 1.

Predators, Parasites and Diseases More susceptible to plague than *M. natalensis*. Distribution of outbreaks of plague in Zimbabwe and South Africa corresponds approximately to the distribution of *M. coucha*, although there are some exceptions (Taylor *et al.* 1981, Venturi *et al.* 2003).

Conservation IUCN Category: Least Concern.

Fr. Souris à mamelles multiples de Guinée; Ger. Guinea-Vielzitzenmaus

Mastomys erythroleucus (Temminck, 1853). Esquisses Zool. sur la Côte de Guinée, p. 160. (The cultivated parts of Guinea.)

Taxonomy Originally described in the genus *Mus*. Until a few years ago, *Mastomys erythroleucus* was thought to be clearly distinguishable from other *Mastomys* by its chromosome number of $2n = 38$. However, there are probably at least three forms with this same chromosome number but with different fundamental number, and which may deserve species status (Volobouev *et al.* 2001). One form has $FN = 40-41$ and occurs in Niger, Chad and Sudan and is now referred to as a separate species *Mastomys kollmannspergeri*. The second form (i.e. this species) has $FN = 50-56$, and is widely distributed throughout sub-Saharan Africa with karyotyped populations from Senegal, Côte d'Ivoire, Mali, Benin, Cameroon, DR Congo and Sudan (and probably also Morocco and Ethiopia). A third form has $FN = 59-60$ and is found in E DR Congo, Uganda and probably Mali and Chad, but so far has not been associated with a separate specific name. Synonyms: *calopus*, *gambianus*, *peregrinus*. Subspecies: none. Chromosome number: $2n = 38$, $FN = 50-56$ (see also above).

Description Medium-sized reddish-brown mouse. Dorsal pelage reddish-brown. Ventral pelage creamy. Colour of dorsal pelage more or less clearly delineated from ventral pelage. Fore- and hindfeet whitish. Tail long (89% of HB in Senegal), dark above, paler below. Skull closely resembles that of *M. natalensis* and *M. huberti*, and can be distinguished by multivariate techniques (Duplantier 1988). Sexually dimorphic: ♂♂ have larger HB, HF and weight than ♀♀. Nipples: 12 (equally spaced from axilla to inguinal region) = 24.

Geographic Variation None recorded.

Similar Species

M. huberti. Smaller mean HB and T; ventral pelage grey; restricted to West Africa; prefers wet areas; nipples $12 \times 2 = 24$; $2n = 32$.

M. kollmannspergeri. Similar mean HB and T; ventral pale grey or white; known only from around L. Chad, geographic limits uncertain; nipples $9-12 \times 2 = 18-24$; $2n = 38$.

M. natalensis. Smaller mean HB and T; tail longer as % of HB; ventral pelage dark grey; also widespread distribution with extensive sympatry in savanna habitats of West and Central Africa; nipples $12 \times 2 = 24$; $2n = 32$.

Praomys daltoni. Smaller mean HB and T; T longer as % of HB (110%); ventral pelage pure white; widespread distribution and

common in savanna habitats of West and Central Africa; nipples: $3 + 2 = 10$. $2n = 36$.

Praomys derooi. Smaller mean HB and T; ventral pelage grey, often with white spot on chest; restricted to savanna habitats from Ghana to W Nigeria; commensal; nipples $3 + 2 = 10$; $2n = 36$.

Distribution Endemic to Africa. Widespread in Sahel, Sudan and Guinea BZs, Northern and Eastern Rainforest–Savanna Mosaics; extends into suitable habitats in Rainforest BZ in West Africa. Recorded from Senegal to Ethiopia, and south to Cameroon and E DR Congo. Isolated populations in Morocco (Cabrera 1932, Tranier 1974).

Habitat Grasslands, disturbed areas, fields, near human habitations and in buildings (Duplantier & Granjon 1988). Occurs on a wide variety of soil types, but not in arid environments (Hubert *et al.* 1977). In Ghana, this species dominated in areas with tree plantations and secondary forest (Decher & Bahian 1999).

*Mastomys erythroleucus*

Abundance Very common. Population explosions occur irregularly; densities vary from 1/ha to more than 100/ha in Senegal (Hubert 1982, Hubert & Adam 1985). In Ethiopia, densities remained below 20/ha during two years of study, with lower densities during the dry season (Afework Bekele & Leirs 1997). When populations are high, these mice are a serious agricultural pest in fields and stores.

Adaptation In semi-arid areas, shortage of food during the late dry season induces a decrease of water loss and cessation of reproduction (Sicard *et al.* 1999). Fats are stored in body tissues during the period of highest availability of seeds in the early part of the dry season, and are used as a source of energy and metabolic water later in the season (Hubert & Demarne 1981).

Foraging and Food Mainly granivorous but other plant parts and insects are also eaten. Seeds of plants of the Cucurbitaceae family predominate in the diet during the early dry season, and seeds of Convolvulaceae during the late dry season. An increase in green vegetation in the diet increases during the wet season and coincides with the start of reproduction. Grass seeds and arthropods are eaten throughout the year (Hubert *et al.* 1981b). Supplementary food, provided experimentally, increased recruitment and survival but was unable to prevent population decline (Hubert *et al.* 1981a).

Social and Reproductive Behaviour Males have larger home-ranges than ♀♀ and move more often. Individual mice are not territorial or aggressive, and they do not form lasting group associations. These characters are even more evident in island populations than in mainland populations in Senegal (Granjon *et al.* 1986, Granjon & Duplantier 1991).

Reproduction and Population Structure Reproduction is seasonal, beginning early in the wet season and lasting well into the dry season (Hubert 1982, Afework Bekele & Leirs 1997). Gestation: 21 days. Litter-size: 11.8 (1–21, $n = 150$; Duplantier *et al.* 1996). Litter-size is higher in maize fields than in other habitats (Afework Bekele & Leirs 1997). Spontaneous ovulation; postpartum oestrus occurs within a few hours of parturition and then again after a few days. Vaginal plug formed after copulation (Brambell & Davis 1941).

Predators, Parasites and Diseases Hubert & Adam (1983) suspected a virus, Bandia virus, to play a role in the dynamics of populations of *M. erythroleucus* but no details of its epidemiology or pathology are known. The presence of a number of human pathogens (*Borrelia crocidurae*, *Leishmania*, several viruses) has been reported from this species in Senegal. Serological tests on these mice have been positive for antibodies against Lassa fever virus and Congo–Crimean haemorrhagic fever virus.

Conservation IUCN Category: Least Concern.

The status of the isolated populations in Morocco is unknown. This species is considered a pest in crops and therefore often controlled.

Measurements

Mastomys huberti HUBERT'S MULTIMAMMATE MOUSE (HUBERT'S MASTOMYS)

Fr. Souris à mamelles multiples de Hubert; Ger. Huberts Vielzitzenmaus

Mastomys huberti (Wroughton, 1908). Ann. Mag. Nat. Hist., ser. 1, 8: 255. Zungeru, N Nigeria.

Taxonomy Originally described in the genus *Mus*. Although *huberti* was traditionally considered a name for a West African *Mastomys* species, Qumsiyeh *et al.* (1990) argued that the name *hildebrandtii* (with a type locality in Kenya) had priority over *huberti* for this species, but without comparing the type material. Their decision was based on the assumption that specimens from Kenya in their study were different from *M. natalensis* from South Africa and conspecific with specimens from Somalia, which Capanna *et al.* (1982) had named as *M. huberti*. Musser & Carleton (1993) thus also referred to this species as *M. hildebrandtii*. However, the karyology for the West African specimens assigned to *huberti* ($2n = 32$, $FN = 44$) is

different from that of the specimens from Kenya that Qumsiyeh considered to be *hildebrandtii* ($2n = 32$, $FN = 50$ – 54). Therefore, these taxa are not synonyms and *M. huberti* is maintained as a valid species, even though specimens from the type region have not yet been investigated karyologically, and the type locality lies outside the geographic range of what is currently called *M. huberti* (Granjon *et al.* 1997b). Synonyms: none. Chromosome number: $2n = 32$, $FN = 44$.

Description Medium-sized dark-grey mouse. Dorsal pelage darkish-grey (young), rusty-brownish (old adults) or blackish (in Senegal). Ventral pelage dark, hairs with greyish tip. Fore- and

hindfeet whitish. Tail long (84% of HB in Senegal), dark above, sometimes somewhat paler below. Skull closely resembles that of *M. natalensis*. Sexually dimorphic: on average ♂♂ have larger HB and HF and weigh more than ♀♀. Nipples: 12 (equally spaced from axilla to inguinal region) = 24.

Geographic Variation None recorded.

Similar Species

M. erythroleucus. Similar mean HB and T; ventral pelage cream; widespread distribution; common; $2n = 38$.

M. natalensis. Smaller mean HB and T; tail longer as % of HB; ventral pelage dark grey; widespread distribution in savanna habitats of West and Central Africa; $2n = 32$.

Pracomys daltoni. Smaller mean HB and T; T longer as % of HB (110%); ventral pelage pure white; widespread distribution and common in natural habitats; nipples: $3 + 2 = 10$. $2n = 36$.

Distribution Endemic to Africa. Sahel and Sudan Savanna BZs of W West Africa. Recorded (and confirmed by karyology) from Senegal, Mauritania, Mali and Burkina (Granjon *et al.* 1997b). Type locality (not karyotyped) in Nigeria. Sympatric with *M. erythroleucus* and *M. natalensis* in parts of its geographic range. Many records are uncertain because information on chromosomes is lacking.

Habitat Humid areas in natural grassland as well as agricultural fields. Also occurs on dry islands in the Saloum Delta in Senegal. Partly syntopic with *M. erythroleucus* in market gardens in Senegal (Duplantier & Granjon, 1988).

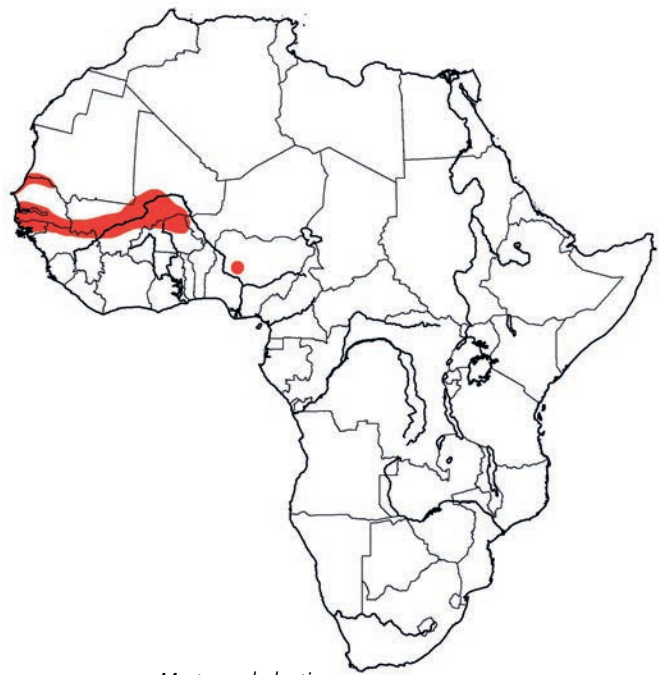

Abundance Common in suitable habitats. During a two-year period (Oct 1988 to Oct 1990) in the Saloum Delta of Senegal, 8–97 individuals were present on a 0.8 ha island (= 10–108/ha) and 19–37 individuals on a 2 ha study area (= 10–18/ha) on the nearby mainland (Granjon *et al.* 1994).

Adaptations Large variation in water metabolism in different individuals. Free water not needed for survival (Granjon *et al.* 1994, Ganem *et al.* 1995). Very good swimming abilities (Duplantier & Bâ 2001).

Foraging and Food Omnivorous. In Senegal, analysis of stomach contents showed that 97% contained insects, 59% grains or starchy tubers, 49% leaves stems and roots, and 9.7% fruit pulp ($n = 145$ stomachs; (Hester 1993).

Social and Reproductive Behaviour Inter-male relationships less aggressive than in *M. natalensis* and *M. erythroleucus* (Granjon *et al.* 1986). Multiple capture results suggested associations between adult ♂♂ (Granjon & Duplantier 1991).

Reproduction and Population Structure Reproductive activity occurs throughout the year in wet habitats (Sicard *et al.* 1999). Gestation: 21 days. Litter-size: 12.2 (1–27) (Duplantier *et al.* 1996). Populations in irrigated fields showed seasonal variations in population structure: in the dry season (Jan–Mar), juveniles represented more than 50% of captures, while in the wet season

Mastomys huberti

(Jul–Nov) old adults represented 50% or more. Pregnancy rate in adult ♀♀ was highest (45%) in Sep (end of wet season) and lowest (3%) in Jan (dry season). Sex ratio in adults was male-biased (J.-M. Duplantier unpubl.).

Predators, Parasites and Diseases Preyed on by Barn Owls *Tyto alba* in the Senegal Delta (Bâ *et al.* 2000). Known to be a carrier of *Borrelia crocidurae* (Godeluck *et al.* 1994, Duplantier & Sene 2000).

Conservation IUCN Category: Least Concern.

Considered to be a serious agricultural pest.

Mastomys kollmannspergeri KOLLMANNSPERGER'S MULTIMAMMATE MOUSE (KOLLMANNSPERGER'S MASTOMYS)

Fr. Souris à mammelles multiples de Kollmannsperger; Ger. Kollmannspergers Vielzitzenmaus

Mastomys kollmannspergeri (Petter, 1957). Mammalia 21: 129. 150 km north of Agadès, on the road from Agadès to In Abbangarit, near Tedjidda-n-Tesemt, where the road splits to In Gal, Aïr region, N Niger.

Taxonomy Originally described in the genus *Rattus*. Specimens from near the type locality (in Niger; see above) have a karyotype similar to one reported earlier from Sudan, Chad and Niger and recognized as a valid taxon different from *Mastomys erythroleucus* (Volobouev *et al.* 2001, Dobigny *et al.* 2002b). All these specimens were therefore attributed to *Mastomys kollmannspergeri*, which originally was described as a subspecies of *Mastomys natalensis*. Morphometric, cytogenetic and molecular data have shown that specimens from the type region of *Mastomys verheyeni* (a limited geographic area around L. Chad) are now considered to be conspecific with *kollmannspergeri* (Robbins & Van der Straeten 1989). The name for this species is provisionally considered to be *M. kollmannspergeri*, with *verheyeni* as a synonym (C. Denys unpubl.; Musser & Carleton 2005), but there may be older names that are applicable. The holotype of *Mastomys kollmannspergeri*, although described as an adult ♀♀, is considerably smaller than the smallest ♀♀ in the type series used for the description of *verheyeni*, so the existence of several *Mastomys* species around L. Chad should not be excluded. Synonyms: *verheyeni*. Subspecies: none. Chromosome number: $2n = 38$, $FN = 40-41$.

Description Medium-sized grey mouse, one of the largest species of *Mastomys*. Dorsal pelage medium-grey. Ventral pelage paler, hairs grey at base, usually with white tip. Upper surface of fore- and hindfeet with rather long white hairs. Tail long (85% of HB) with rather long hairs. Skull typical of *Mastomys*, but molars wider and molar row longer than in other *Mastomys* species; interorbital constriction narrow. Males slightly larger than ♀♀ in the specimens from around L. Chad. Nipples: 9–12 (equally spaced from axilla to inguinal region) = 18–24.

Geographic Variation None recorded.

Similar Species

M. erythroleucus. Similar mean HB and T; ventral pelage cream; widespread distribution; common; $2n = 38$, $FN = 50-56$.

M. natalensis. Smaller mean HB and T; tail longer as % of HB; ventral pelage dark grey; widespread distribution; $2n = 32$.

Distribution Endemic to Africa. Borders of the Sudan and Sahel Savanna BZ. Karyotypically known specimens recorded from the area immediately surrounding L. Chad in Nigeria and Cameroon; also recorded in S Chad and N Niger. Eastern and western limits unknown; may extend into large areas of Sahel and Sudan BZs, and parts of Sahara Arid BZ in Niger, Chad and Sudan (red line on map).

Habitat In Chad, found predominantly in annually flooded habitats characterized by a clay-rich soil with wide cracks, often with *Acacia seyal* as the main vegetation. In Niger, lives in open grassland habitats with desiccation cracks, and also near camps and in a village (Granjon *et al.* 2004).

Abundance In Zakouma N. P. in Chad, *M. kollmannspergeri* and *M. erythroleucus* were equally abundant and were about twice as common as other rodents. In other areas in Chad, it is not uncommon and may occur with other species of *Mastomys* (Robbins & Van der Straeten 1989; E. Van der Straeten pers. comm.).

Remarks Reproduction may be seasonal. Near L. Chad, in late Nov 1970, most trapped animals were young, and four out of eight ♀♀ were pregnant; in Aug 1972, nearly all animals were adults, ten out of 17 ♀♀ were pregnant or had recently given birth. Litter-size: 12 ($n = 1$) (E. Van der Straeten, unpubl.). In Chad, embryo numbers were 12, 12, 8 and 7/litter ($n = 4$; Granjon *et al.* 2004).

Conservation IUCN Category: Least Concern.

Fr. Souris à multiples mamelles du Natal; Ger. Natal-Vielzitzenmaus

Mastomys natalensis (Smith, 1834). S. Afr. Quart. J., ser. 2, 2: 156. Port Natal (= Durban), South Africa.

Taxonomy Originally described in the genus *Mus*. For many years, the name *M. natalensis* has been used as the name for *Mastomys* mice from all over Africa (many papers actually using the naming *Praomys natalensis*). Recent studies have shown that there are not less than eight species of *Mastomys*, each characterized by its own karyotype, and now *M. natalensis* is restricted to populations with a chromosome number of $2n = 32$, $FN = 52–54$. The species has an extremely large geographic range (see below), and specimens from South Africa and from Senegal are reported to be conspecific (Granjon *et al.* 1996). However, chromosomal variation within the currently recognized species may indicate that *M. natalensis* is a species group with additional species still to be recognized. Synonyms: *caffer*, *cuninghamei*, *durumae*, *effectus*, *evelyni*, *fumatus*, *gardulensis*, *fusca*, *hildebrandtii*, *illovoensis*, *ismaillae*, *itigiensis*, *kerensis*,

komatiensis, *longicaudatus*, *microdon*, *muscardinus*, *neumanni*, *ovamboensis*, *pallida*, *panya*, *rufa*, *somereni*, *tana*, *tinctus*, *ugandae*, *victoriae*, *zuluensis*. Subspecies: none. Chromosome number: $2n = 32$, $FN = 52–54$.

Description Small, grey mouse. Dorsal pelage darkish-grey (young) to rusty-brownish (old adults). Ventral pelage dark grey; hairs with paler tip. Eyes dark and bulbous. Ears large, naked, rounded at tip. Fore- and hindfeet whitish. Tail long (ca. 100% of HB), dark above and below. Skull distinguishable from *M. coucha* and *M. huberti* by multivariate techniques only, but with considerable misclassification (Dippenaar *et al.* 1993, Lecompte *et al.* 2002b). Spermatozoa and genital morphology slightly different from other species of *Mastomys* (Gordon & Watson 1986, Lavrenchenko & Baskevich 1996) but these characters are cumbersome for species identification. Nipples: 12 (equally spaced from axilla to inguinal region) = 24.

Geographic Variation Uncertain.**Similar Species**

M. erythroleucus. Larger mean HB and T; ventral pelage cream; widespread distribution; common; overlap in geographic range in West Africa but not in eastern or southern Africa; $2n = 38$, $FN = 50–56$.

Praomys daltoni. Smaller mean HB and T; T longer as % of HB (110%); ventral pelage pure white; widespread distribution and common in savanna habitats of West Africa but not southern Africa; nipples: $3 + 2 = 10$; $2n = 36$.

M. coucha. Similar HB and T; ventral pelage dark grey; partially sympatric in southern Africa; common; prefers low altitude/high rainfall regions; nipples $12 \times 2 = 24$; $2n = 36$.

M. awashensis, *M. kollmannspergeri*, *M. pernanus*, *M. shortridgei*, *Myomyscus angolensis* and *Praomys derooi* are narrowly sympatric with *M. natalensis* in small and restricted areas (see profiles and maps).

Distribution Endemic to Africa. Very widely distributed throughout many biotic zones in western, central, eastern and

*Mastomys natalensis*

southern Africa but not in highland habitats such as alpine meadows. Recorded from Senegal, Mali, Benin, Burkina and Niger in West Africa to Ethiopia and Somalia in the east, and southwards through Kenya and Tanzania to Namibia and the eastern part of South Africa. *Mastomys natalensis* prefers low altitude/high rainfall regions (>600 mm annual rainfall), while *M. coucha* has a preference for higher altitude/relatively drier parts of South Africa (Dippenaar *et al.* 1993, Venturi *et al.* 2003). The species is absent from natural habitats in the Rainforest BZ in central Africa, but has been recorded in human settlements in that zone. Many records of *M. natalensis* throughout Africa, and the associated biological information, are uncertain because of lack of karyological identification and the large geographic overlap with most other *Mastomys* species. Molecular identification of tissue samples should resolve the distribution of this species in the near future.

Habitat Grassland, with or without bushes, thickets or trees, and disturbed patches. Very common in fields and fallow land as well as in and around buildings in human settlements. Does not occur in the rainforest but may be found in human settlements and agricultural fields within the Rainforest BZ. At the extremes of its geographic range may be limited to specific habitats, e.g. only inside villages in Senegal (Duplantier *et al.* 1990). It is a common pioneer species after fire (Meester *et al.* 1979).

Abundance One of the commonest species in savanna habitats, with densities of up to 1000/ha in disturbed areas. In farmland and fallow areas in Tanzania, 85% of the captured small mammals were multimammate mice while in natural miombo woodland and moist grassland 50 km away, they comprised only 27% of the trapped small mammals in a community of 17 different species (Leirs 1995). The species is well known for its seasonal fluctuations in numbers and irregular population explosions: maximum population numbers may be up to 40 times minimum numbers (Leirs *et al.* 1996). In a natural thicket-grassland savanna in Malawi, multimammate mice comprised 47% of small rodents in a community of ten species on an annual basis; densities fluctuated from 1/ha (dry season) to 40/ha (wet season) (Happold & Happold 1991). Abundance may be patchy, large numbers occurring in (preferred) habitats while other nearby habitats have no (or very few) individuals. Often the commonest of all rodents in food stores and houses where they may be very abundant and are regarded as a serious pest.

Adaptations Terrestrial and nocturnal. Activity is highest during the first half of the night, starting immediately after sunset. Multimammate mice can make their own burrows, but often use existing burrows or cracks in the soil. They can easily dig to a depth of more than 500 mm and can jump over 600 mm high (S. Vibe-Petersen unpubl.). The nest is constructed underground, often not very deep, and is a simple cavity lined with dried plant parts torn to pieces. The digestive system is adapted to a generalist diet (Perrin & Curtis 1980). Subadult animals become reproductively active very quickly after a period of heavy rainfall (Leirs *et al.* 1993, 1994). Survival of subadult and adult animals is affected in a complex way by a combination of density-dependent and density-independent (rainfall) factors (Leirs *et al.* 1997a).

Foraging and Food Opportunistic omnivores. The diet includes seeds of cereals, leaves and stems of grasses and dicotyledonous plants, insects and sometimes carrion (Leirs *et al.* 1994). Contents of stomachs reported in the literature often relate to the kind of habitat where the studies were carried out, illustrating the opportunistic nature of foraging. Seeds often make up a large proportion of the stomach contents (Field 1975, Taylor & Green 1976). Multimammate mice dig up newly-planted maize seeds, causing huge loss of potential harvest. They also climb maize stalks and damage the cobs. They are generally considered a pest in agriculture throughout their geographic range.

Social and Reproductive Behaviour Very lively, but generally not aggressive (although reported more aggressive than other *Mastomys* species). Home-ranges show a wide degree of overlap and there is no evidence of territoriality. For resident animals, home-ranges are rather small, ca. 1000 m², larger for males than for females (Leirs *et al.* 1997a). At times of dispersal, animals can move several hundred metres in only a few hours.

Reproduction and Population Structure Reproduction very seasonal, starting soon after the onset of the wet season and lasting well into the dry season. Germinating seed and young grass seedlings in the diet stimulate reproductive maturation (Leirs *et al.* 1994, Firquet *et al.* 1996). Mean litter-size varies widely between populations, e.g. 10–12 in Tanzania (with a reported maximum litter-size of 23) (Leirs 1995), 6.5 in Senegal (Duplantier *et al.* 1996) and 4.5 in E DR Congo (Rahm 1970). Gestation: 21–22 days. Postpartum oestrus a few days after parturition; mean litter interval 28 days during the breeding season. Copulatory plug only rarely formed (Johnston & Oliff 1954). Young altricial at birth; eyes open Day 15; weaned Day 21 (Baker & Meester 1977). Young animals rarely mature during the season of birth; they become reproductively active after abundant rainfall and vegetation growth in the next breeding season. When such rains come early, subadults may start reproducing at the age of three months. Most animals die towards the end of their first breeding season when not more than about 12 months of age. Sex ratio of subadults near 1:1, but strongly biased towards ♀♀ during the breeding season. Population structure is strongly influenced by the large litters, high reproductive rate and early mortality. In Malawi, the population in thicket-grassland savanna was composed primarily of subadults at end of dry season (when the population is at its lowest – see above); most of these subadults matured during the early wet season. Young began to enter the population towards the end of the wet season and early dry season, and soon formed the majority of the population as the adults died. By mid-dry season all young had become subadults. Population turnover was rapid due to dispersal of young, immigration of new animals from elsewhere and mortality of animals of all age-groups; individuals rarely live for more than 12 months (Happold & Happold 1991).

Predators, Parasites and Diseases Multimammate mice are a common prey of many owls, raptors, snakes and small ground-dwelling carnivores. Predation is an important source of mortality. The mice adapt their foraging behaviour and become more cautious in open spaces when the presence of raptors in the environment increases (Mohr *et al.* 2003). Attracting or excluding avian predators

has complex and sometimes compensatory effects on survival, reproduction and dispersal of the mice so there is no clear effect on the resulting population densities (Vibe-Petersen *et al.* 2006). Multimammate mice are the main reservoir for Lassa fever virus in West Africa, and also implicated in the epidemiology of bubonic plague and leptospirosis. Very little is known about diseases affecting the mice themselves.

Conservation IUCN Category: Least Concern.

One of the commonest small mammals in Africa. Considered to be a serious agricultural pest in many regions.

Mastomys pernanus DWARF MULTIMAMMATE MOUSE (DWARF MASTOMYS)

Fr. Souris à mamelles multiples naine; Ger. Zwerg-Vielzitzenmaus

Mastomys pernanus (Kershaw, 1921). Ann. Mag. Nat. Hist., ser. 9, 8: 568. Amala River, Kenya (= upper course of the Mara River, situated at 00° 58' S, 25° 24' E according to Misonne & Verschuren 1964).

Taxonomy Originally described in the genus *Rattus*. The generic position of this species has been questioned, and recent molecular evidence indeed suggests that it should no longer be considered a member of *Mastomys* but is more closely related to *Hylomyscus* (Lecompte *et al.* 2002b). Synonyms: none. Chromosome number: not known.

Description Very small, grey mouse, smaller than all other *Mastomys*. Dorsal pelage darkish-grey with, in most specimens, an ochraceous stripe between flanks and ventral pelage. Ventral pelage grey, belly slightly washed with buff; hairs grey with white tip; small white chest patch in some individuals. Prominent spot of white hairs behind each ear. Tail long (85% of HB), well covered with short hairs (up to 1.5 mm). Typical *Mastomys* skull; mesopterygoid fossa triangular, very narrow on the posterior margin of the palatine and relatively wide towards the end (Van der Straeten 1999). Nipple number: not known.

Geographic Variation None recorded.

Similar Species

M. natalensis. Much larger mean HB and T; tail longer as % of HB; ventral pelage dark grey; widespread distribution and common; nipples 12 × 2 = 24; 2n = 32.

Distribution Endemic to Africa. Southern part of Somali–Masai Bushland BZ. Recorded from N Tanzania and S Kenya, with one morphologically somewhat aberrant specimen from Dakawa in C Tanzania. Unconfirmed records from Rwanda (Van der Straeten 1999).

Mastomys pernanus

Habitat The one specimen in Dakawa, Tanzania, was trapped in *Brachystegia* woodland (W. Verheyen, R. Verhagen & H. Leirs, unpubl.).

Abundance The very low number of specimens in collections indicates that the species is rare or not easily captured with usual trapping techniques. Only a single specimen was trapped at Dakawa Ranch, Tanzania, although 1333 other small mammals were collected at the same locality over a period of two years (W. Verheyen, R.

Verhagen & H. Leirs, unpubl.). In Rwanda, however, 14 out of 201 rodent specimens in owl pellets were identified as *M. pernanus* (Misonne & Verschuren 1964).

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Mastomys shortridgei SHORTRIDGE'S MULTIMAMMATE MOUSE (SHORTRIDGE'S MASTOMYS)

Fr. Souris à mammelles multiples de Shortridge; Ger. Shortridges Vielzitzenmaus

Mastomys shortridgei (St Leger, 1933). Proc. Zool. Soc. Lond. 1933: 411. Okavango–Omatako junction, Grootfontein District, Namibia.

Taxonomy Originally described in the genus *Myomys*. Van der Straeten & Robbins (1997) confirmed the classification of this species in the genus *Mastomys*. It has been suggested that *M. shortridgei* was conspecific with *M. angolensis*, but the nipple arrangement is different in the two species, and *angolensis* is now placed in the genus *Myomyscus*. Referred to as *Myomys shortridgei* by Shortridge (1934) and as *Praomys shortridgei* by Smithers (1971). Synonyms: *legerae*. Subspecies: none. Chromosome number: 2n = 36, FN = 50.

Description Medium-sized dark grey mouse. Dorsal pelage dark grey, sometimes nearly black; hairs grey at base with buffy tip. Ventral pelage grey; hairs grey at base with white tip. Upper surface of fore- and hindfeet white. Tail long (ca. 88% of HB), dark above and below. Skull typical of *Mastomys*, but pterygoid fossa wider than in other *Mastomys* and the anterior palatal foramina do not reach the inner root of M¹ (Meester *et al.* 1986). There is confusion in the literature about the number of nipples: Gordon (1985) mentioned two rows of eight nipples, but Van der Straeten (2001 in litt.) confirmed that the holotype has two rows of five nipples each (total ten).

Geographic Variation None recorded.

Similar Species

M. natalensis. Smaller mean HB; tail longer as % of HB; ventral pelage dark grey; widespread distribution and common; nipples 12 × 2 = 24; 2n = 32.

Distribution Endemic to Africa. Zambezi Woodland BZ. Usually thought to be endemic to extreme NW Botswana and NE Namibia in the region of the confluence of Okavango and Kwito rivers. However, Crawford-Cabral (1998) reported a few specimens from scattered localities in E Angola.

Habitat Marshes and the banks and terraces of rivers. Sometimes commensal.

Abundance Uncertain. Smithers (1971) recorded that it occurs with *M. natalensis* in Botswana but was the least common of the two

Mastomys shortridgei

species. Rare in collections from Angola (Crawford-Cabral 1998), although Shortridge (1934) mentioned that it was plentiful locally.

Remarks Terrestrial and nocturnal. Granivorous; probably omnivorous (Smithers 1971). None of 18 ♀♀ collected in Apr and May in NW Botswana showed signs of breeding, but a tiny juvenile was trapped in Feb (Smithers 1971).

Conservation IUCN Category: Least Concern.

GENUS *Muriculus* Ethiopian Striped Mouse

Muriculus Thomas, 1903. Proc. Zool. Soc. Lond. 1902 (2): 314. (publ. 1903). Type species: *Mus imberbis* Rüppell, 1842.

Muriculus imberbis.

A monotypic genus confined to higher altitudes in Ethiopia. The genus has been allied to *Mus* and *Zelotomys* (Osgood 1936) and especially to *Mus* (Ellerman 1941). The genus is characterized by pro-odont incisors (but without notch on the posterior side as in *Mus*), the cutting edges of the incisors form a semi-circular shape (similar to those of *Ammodillus*), the rostrum is thin and narrow (especially when viewed laterally), and the coronoid process on the mandible is low without a point and is approximately the same height as the articular condyle (Figure 75). There is a dark middle-dorsal stripe. The single species is *Muriculus imberbis*.

Figure 75. Skull and mandible of *Muriculus imberbis* (BMNH 28.1.1.153).

D. W. Yalden

Muriculus imberbis ETHIOPIAN STRIPED MOUSE

Fr. Souris à crinière; Ger. Simien-Maus

Muriculus imberbis (Rüppell, 1842). Mus. Senckenberg. 3: 110, pl. 6 (Fig. 4). Enschetgab, Ethiopia. 2800 m.

Taxonomy Originally placed in the genus *Mus*. Synonyms: *chilaloensis*. Subspecies: two. Chromosome number: not known.

Description Distinctive very small murine, with pro-odont upper incisors that distinguish the skull from related species. Pelage soft and dense. Dorsal pelage brown to olive-grey, with slight speckling; hairs dark grey at base, brownish at tip; some all-black hairs especially along mid-dorsal line. Faint mid-dorsal stripe along the middle of the back, which does not extend as far forward as the head nor over the rump. (Pelage colour very similar to *Mus mahomet* except for mid-dorsal

stripe.) Flanks paler, less black, often with yellowish line separating dorsal and ventral colours. Ventral pelage greyish to buff-white, with tinge of orange-buff in some individuals. Ears grey, with sparse short buffy hairs. Fore- and hindfeet whitish-grey dorsally. Tail (ca. 70% of HB) very clearly bicoloured with small hairs; dark above, pale below. Skull: see genus profile. Nipples: not known.

Geographic Variation

M. i. imberbis: Ethiopian plateau west of the Rift Valley. Ventral pelage greyish-white or buff.

*Muriculus imberbis*

M. i. chilaloensis: south-eastern plateau of Ethiopia, east of the Rift Valley. Ventral pelage white with a yellow tinge.

Similar Species

Mus mahomet. Very similar, but on average slightly smaller, lacks the mid-dorsal stripe; incisors orthodont (not pro-odont).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of Ethiopia. Confined to the grasslands (woina dega) of the high plateaux of Ethiopia, from 1900 to 3400 m. Known from only about nine localities (Yalden *et al.* 1976, Yalden & Lagen 1992).

Habitat Typically open upland grasslands, but also reported as commensal in Simien Mts (Müller 1977).

Abundance Rare. Only 12 specimens known (Yalden *et al.* 1976; Yalden & Lagen 1992). Collecting in Ethiopia (1968–98, $n = \text{ca. } 6300$ rodents) yielded no individuals of this species. Some individuals were found in houses in the Simien Mts in the 1970s (Müller 1977), but none were recorded there in the 1990s (Nievergelt *et al.* 1998). Despite extensive recent trapping, not known to occur in the Bale Mts.

Remarks Probably terrestrial and nocturnal. The pro-odont upper incisors suggest that these mice may dig their own burrows in the otherwise rather open habitat. Presumably granivorous. One juvenile found in Sep (label, BMNH).

Conservation IUCN Category: Endangered.

The grassland habitat is threatened by continuing modification and destruction by humans and their livestock; Yalden *et al.* (1976) speculated that the species was less common than 50 years previously. Schlitter (1989) recommended that the species should be classified as Vulnerable.

GENUS *Mus*

Old World Mice and Pygmy Mice

Mus Linnaeus, 1758. Syst. Nat., 10th edn., 1: 59. Type species: *Mus musculus* Linnaeus, 1758.

*Mus minutoides*

In Africa, the genus *Mus* is represented by about 20 species (Table 37). Species within the genus occur throughout most of the continent and are recorded from forest, savanna, highland grassland and semi-

arid habitats, and from sea level to ca. at least 2000 m. The only habitats where *Mus* does not occur are rainforests and arid deserts. Extraliminally, the genus is represented throughout the Old World. One species, *Mus musculus*, has been introduced into all continents (including Africa) and many islands, and has, in general, proved to be a very successful colonizer.

The genus, as exemplified by African species, is characterized by small size (HB: ca. 43–90 mm, GLS: 16–25 mm, WT: 3–20 g), delicate build, shortish pelage and shortish tail without a terminal pencil. Upper incisors opisthodont or slightly pro-odont; uniquely there is a notch on the posterior face of the upper incisors. Other diagnostic skull characters include pronounced masseteric knob on the zygomatic plate near the lower edge, anterior palatal foramina,

Table 37. Species in the genus *Mus*. Arranged in order of increasing mean head and body length. (n. d. = no data.)

| | Medium-dark grey, white tips | n. d. | NE and C Angola, S and W DR Congo |

which extend well posterior to the anterior end of M¹, laminae of the molar teeth, which tilt posteriorly, t1 of M¹ distorted posteriorly and hence almost in line with t4 and t5, and very small M³ (Figure 76).

There is great variation in the distribution and abundance of species of *Mus* in Africa. Some are widespread and numerous (*M. minutoides*, *M. musculoides*, *M. setulosus*), some have very limited distributions (e.g. *M. bufo*, *M. goundae*, *M. oubanguii*), and others are known from only few widely scattered localities and their full geographic range is uncertain (e.g. *M. callewaerti*, *M. sorella*, *M. tenellus*). Typically, individuals of many species of *Mus* are numerous in favoured environments and contribute a relatively large percentage to the total rodent community; they have short life expectancies and high fecundity, and the population

turnover is rapid. They form an important source of food for smaller predators, and their remains often contribute a high percentage of total prey in the pellets of owls. Individuals of *Mus* spp. are mostly gregarious and non-territorial. They are granivorous or omnivorous, their small size necessitating that they eat only high quality foods.

The genus is divided into four subgenera, two of which are represented in Africa: subgenus *Mus* (typical Old World Mice) distinguished by larger size, flat anterior face to the zygomatic plate, masseteric knob at the lower anterior corner of the plate, and M³ with two (often inconspicuous) laminae (2 spp. – *M. musculus*, *M. spretus*); and the subgenus *Nannomys* (African Pygmy Mice), distinguished by smaller size, convex anterior face to the zygomatic plate, masseteric

knob at the lower centre of the plate, and M^3 usually without laminae (18 spp.). In the past, *Nannomys* was referred to as *Leggada* (e.g. De Graaff 1981, Smithers 1983, Meester *et al.* 1986) and has been raised to the rank of genus by some authorities (e.g. Allen 1939, Roberts 1951, Bonhomme 1992). The distinction between the two subgenera is not always clearcut (Petter 1963b) although, in West Africa, for example, the two can be easily separated (Rosevear 1969). For Africa, the recognition of *Nannomys* as a subgenus appears to be warranted (Musser & Carleton 2005). Here, the African species are allocated to the genus *Mus* (rather than *Leggada* or *Nannomys*) following Petter & Matthey (1975) and Musser & Carleton (2005).

Because all species of *Mus* (especially *Nannomys*) are small and morphologically similar, distinctions between species are often blurred. Geographical variation within widespread species is common and has resulted in the naming of many forms (species or subspecies), many of which are now regarded as synonyms. Within *Nannomys*, some species have been classified into groups implying at least some degree of relationship between the group-members. Based on some external and craniodental morphological similarities, Petter (1981) defined a 'sorella group', which included *M. sorella*, *M. goundae*, *M. neavei*, *M. oubanguii*, *M. kasaicus* (considered here to be conspecific with *M. minutoides* [but see Musser & Carleton 2005]) and two other species (*acholi*, *wamae*) now considered to be conspecific with *M. sorella*. Musser & Carleton (1993, 2005) indicate that the diagnostic characters of *M. baoulei* are closely similar to those of the *sorella* group, but suggest that the relationship of *M. baoulei* to other members of the *sorella* group requires fresh assessment. Musser & Carleton (2005) do not mention either *M. minutoides* or *M. musculoides* as belonging to the *sorella* group. Based on morphology of the sex chromosomes, two

groups within *Nannomys* can be distinguished. The first group (with acrocentric X and Y chromosomes) includes *M. bufo*, *M. indutus*, *M. mattheyi*, *M. mahomet* and *M. tenellus*, which all have 36 acrocentric chromosomes (diploid number $2n = 36$, and fundamental number $FN = 36$). Two additional species belong to this group: *M. setulosus* ($2n = 36$, $FN = 36$), which is distinguished from the others by large heterochromatin additions on several pairs of autosomes, and *M. haussa*, which is distinguished by a pericentric inversion and varying numbers of autosomal centric fusions ($2n = 28-34$, $FN = 38$) (Veyrunes *et al.* 2004). The second group (with metacentric X and/or Y chromosomes formed by sex-autosome translocations) includes *M. triton*, *M. oubanguii*, *M. musculoides*, *M. minutoides* and *M. goundae* (Matthey 1966a, b, Jotterand 1972, Veyrunes *et al.* 2004). This group is of special interest because of the large variation in the number and morphology of chromosomes between populations and even within populations ($2n = 18-34$, $FN = 30-36$). This is particularly evident for *M. minutoides* and probably also for *M. triton*. This diversity most likely indicates the occurrence of cryptic species (Veyrunes *et al.* 2004). In the absence of chromosomal data, the other species have not yet been assigned to either group (i.e. *M. baoulei*, *M. callewaerti*, *M. neavei*, *M. orangiae*, *M. setzeri* and *M. sorella*). Consequently, it is not yet possible to determine if the *sorella* group of Petter (1981) corresponds to the second of the groups based on chromosome morphology (although there is at least some overlap in species composition); pending resolution of this problem, the affinities of species to these groups are not given in the species profiles. Species in the genus may be distinguished by size, pelage colour, skull characters and karyology.

Mus baoulei BAOULE PYGMY MOUSE

Fr. Souris naine de Baoulé; Ger. Baouli-Zwergmaus

Mus baoulei (Vermeiren & Verheyen, 1980). Rev. Zool. Afr. 94: 573. Lamto, Côte d'Ivoire.

Taxonomy Originally described in the genus *Leggada*. Subgenus *Nannomys*. Synonyms: none. Chromosome number: $2n = 20$, $FN = 32$ (M. Tranier unpubl.).

Description Very small mouse. Dorsal pelage grey-brown to dark-brown; hairs grey at base, brown at tip. Flanks paler than dorsal pelage, becoming yellowish- to reddish-brown towards ventral surface. Ventral pelage pure white, clearly delineated from dorsal pelage on flanks and cheeks. One ochre spot below each eye and one below each ear. Tail short (50–65% of HB), brown above, paler below, covered with fine and short hairs. Skull: anterior palatal foramina very long (3.65 mm, range 3.65–4.70), and longer than for sympatric species of *Mus*. Nipples: not known.

Geographic Variation None recorded.

Similar Species

M. goundae. Chromosome number: $2n = 16-19$, $FN = 30$; Central African Republic.

M. oubanguii. Chromosome number: $2n = 28$, $FN = 30-34$; Central African Republic.

M. kasaicus, *M. neavei* and *M. sorella*. All belong to the 'sorella' group of Petter (1981), are of similar size, and have a more easterly distribution.

M. setulosus. A little larger; chromosome number: $2n = 36$, $FN = 36$; no auricular spots; relatively longer tail; West to East Africa.

M. musculoides. Brighter pelage; chromosome number: $2n = 18-34$, $FN = 36$; relatively longer tail; West and East Africa.

M. haussa. Paler colour; chromosome number: $2n = 28-34$, $FN = 38$; West Africa.

M. mattheyi. Chromosome number: $2n = 36$, $FN = 36$; West Africa.

Cranial and dental characters also enable discrimination between these species (Vermeiren & Verheyen 1980, Musser & Carleton 1993).

Distribution Endemic to Africa. Guinea Savanna BZ and Northern Rainforest–Savanna Mosaic. Known only from E Guinea, Côte d'Ivoire and Togo (Vermeiren & Verheyen 1980, Musser & Carleton 1993, Robbins & Van der Straeten 1996).

Habitat Savanna.

Abundance Uncertain; may be locally abundant (e. g. Lamto, Côte d'Ivoire, cf *M. musculoides*, *L. setulosus*) (Vermeiren & Verheyen 1980).

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Mus bufo TOAD PYGMY MOUSE (RWENZORI MOUSE)

Fr. Souris naine crapaud; Ger. Kröten-Zwergmaus

Mus bufo Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 145. Rwenzori East, Uganda, 6000 ft (1830 m).

Taxonomy Subgenus *Nannomys*. Morphologically similar to sympatric *Mus triton* but different in external, skull, dental, karyological and ecological characters (F. Dieterlen unpubl.). The form *ablutus* from Idjwi I. in L. Kivu could be a valid subspecies (Allen & Loveridge 1942). Electrophoretic analysis of protein enzymes at 24 loci indicates that *M. bufo* is more closely related to *M. gratus* (= *M. minutoides*) than to *M. triton* (Van Rompaey *et al.* 1984). Synonyms: *ablutus*, *wambutti*. Subspecies: none currently recognized. Chromosome number: 2n = 36, FN = 36 (Jotterand-Bellomo 1988, Maddalena *et al.* 1989).

Description Small mouse, smaller than sympatric *M. triton*. Dorsal pelage stiff and thick, hairs long (8–9 mm). Dorsal pelage dark coppery-brown, rather variable; hairs slate-grey to black at base, dull reddish-brown at tip; softer underfur black, grey or buff. Rump darkish. Ventral pelage buff to greyish-buff, shorter than dorsal pelage. Yellowish line between dorsal and ventral pelage in some individuals. Ears dark with scattered short buffy hairs. No postauricular or subauricular spots. Upper surface of forefeet and hindfeet brown with a tinge of buff. Tail long (ca. 97% of HB), finely scaled, with dense short blackish bristles above, whitish below. Skull stoutly built but less so than in *M. triton*; anterior palatal foramina long, extending nearly to the middle of M¹; mesopterygoid fossa broad compared to *M. triton* (Thomas 1906a). Nipples: 3 + 1 = 8.

Geographic Variation None currently recognized (see Taxonomy).

Mus bufo

Similar Species

M. triton. Larger; tail shorter (71% of HB); ventral pelage paler (usually greyish-white); different chromosome number (see species profile).

Distribution Endemic to Africa. Afromontane–Afroalpine BZ in montane regions of the Albertine Rift Valley, normally 1500–3000 m (Misonne 1963, Delany 1975, F. Dieterlen unpubl.). Recorded in Upper Ituri region west of L. Albert and on both sides of the Albertine Rift Valley from ca. 01° N to ca. 03° S. Specific locations include Rwenzori Mts (DR Congo, Uganda); Virunga Mts and mountains west of L. Edward (DR Congo); and on both sides of L. Kivu (E DR Congo, W Rwanda, NW Burundi) (Elbl *et al.* 1966, Dieterlen 1967a, Rahm 1967, Maddalena *et al.* 1989, J. Kerbis Peterhans, in litt.). One record from Itombwe Mts, west of L. Tanganyika (von Wettstein-Westersheim 1923). Records from lowland forests below 1000 m need verification, especially Ituri Forest (the type locality of *M. b. wambutti*; Lönnberg & Gyldenstolpe 1925) and Irangi, E DR Congo (Rahm 1967). An extralimital record from the Aberdare Mts, Kenya (Misonne 1963) also needs verification (not shown on map).

Habitat In Kahuzi-Biega N. P., E DR Congo (at 2300–2400 m), preferred habitats are bamboo forest (*Arundinaria alpina*) and stands of *Hagenia abyssinica*, both with grass cover (*Panicum massaiense*) (F. Dieterlen unpubl.). Other habitats include secondary growth on the edge of dense montane forest (2000–2200 m), low and dense afroalpine vegetation (e.g. with *Erica*, *Senecio*, *Lobelia*, *Helichrysum*) on the peak of Mt Kahuzi, E DR Congo (3260–3308 m), and dense stands of *Pennisetum purpureum* in the cultivated zone west of L. Kivu, DR Congo (1500–1900 m). On Rwenzori Mts, Uganda, recorded in grassland (1500 m), low montane forest (1900 m), high montane forest (2600 m) and bamboo (2960 m) (Kerbis Peterhans *et al.* 1998).

Abundance Generally rare in the cultivated zone west of L. Kivu (1500–1900 m). Less common than *M. minutoides* on Idjwi I. in L. Kivu (Rahm & Christiaensen 1966). Often occurs sympatrically with *M. triton* and *M. minutoides* in E DR Congo; e.g. at five locations, *M. bufo* comprised 4.38% of all small mammals (*M. minutoides* 8.24%, *M. triton* 3.91%, $n = 2340$) although the percentage values varied according to locality from 0.7% to 6.5% (Rahm 1967). Numbers varied from month to month over four years (at a single locality); *M. bufo* was

normally the second or third commonest species of the three species of *Mus*, and much less abundant than *M. minutoides* (Rahm 1967). More common in selected habitats in Kahuzi-Biega N. P., E DR Congo.

Adaptations Mainly nocturnal (Delany 1975, Kerbis Peterhans *et al.* 1998).

Foraging and Food Herbivorous, occasionally omnivorous. Most stomach contents (eight of 13) contained exclusively starch-like vegetable material, a whitish-brownish pulp of seeds and tubers; five stomachs contained animal food (chitinous parts, fibres, parts of intestines) comprising only up to ca. 20% of stomach contents (F. Dieterlen, unpubl.).

Reproduction and Population Structure Seasonal trends in reproduction not known. A few pregnant and/or lactating ♀♀ recorded in different seasons. Embryo number: 3 and 4 ($n = 2$). As for other species of the genus *Mus*, captures of ♂♂ outnumber ♀♀ (36 : 25; F. Dieterlen unpubl.).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

***Mus callewaerti* CALLEWAERT'S PYGMY MOUSE**

Fr. Souris naine de Callewaert; Ger. Callewaerts Zwergmaus

Mus callewaerti (Thomas, 1925). Ann. Mag. Nat. Hist., ser. 9, 15: 668. Lualaba, Luluabourg, DR Congo. 610 m.

Taxonomy Subgenus *Nannomys*. Described in the genus *Hylonomys* (Thomas 1925), a genus distinguished from *Leggada* (= *Nannomys*) by the presence of pro-odont incisors (a character now known to be present in several species of *Leggada*). *Hylonomys* now synonymized with *Mus* (Musser & Carleton 1993, 2005). Synonyms: none. Chromosome number: not known.

Description The largest species of the genus, similar externally to *M. triton*. Pelage stiff, dense and coarse. Dorsal pelage medium-brown, hairs dark grey at base, with subterminal medium brown

band and black tip. Ventral pelage whitish-grey; hairs dark grey on basal half, off-white on terminal half. (Hill & Carter [1941] state that ventral pelage may have a pale pinkish-brown tinge especially on chest.) Ears short, brown. Lips and chin white. No postauricular or subauricular spots. Fore- and hindfeet dirty-white. Tail short (ca. 50% of HB), indistinctly bicoloured, brown above, whitish below. Skull: large for the genus; supraorbital crests well developed; auditory bullae large; incisor teeth white on anterior surface, slightly pro-odont. Nipples: not known.

Geographic Variation None recorded.

Similar Species

M. triton. Smaller; ventral pelage grey; supraorbital crests on skull absent; auditory bullae small; incisor teeth yellowish-orange on anterior face; sympatric at some localities (e.g. Chitau, Angola).

M. sorella. Much smaller; ventral pelage pure white.

M. minutoides. Much smaller; dorsal pelage brownish-buff; ventral pelage pure white; incisor teeth yellowish on anterior surface.

Distribution Endemic to Africa. Zambezan Woodland BZ and Southern Rainforest–Savanna Mosaic. Recorded from C and NE Angola and S and SE DR Congo. Altitudes from 610 m (holotype) to 1810 m (SE DR Congo) (Crawford-Cabral 1998). Sympatric with *M. triton*.

Habitat ‘Forest’ (holotype in SE DR Congo; Cabrera & Ruxton 1926) and savanna (Sanborn 1952).

Abundance Uncertain; known by only a few specimens. Recorded as ‘peu commun’ (Sanborn 1952).

Remarks One specimen had eaten fruits of prickly pear *Opuntia* sp. In Angola, Hill & Carter (1941) remarked ‘Apparently in the debris they live on the many insects frequenting such places.’ Females collected in Jul and Aug were ‘apparently lactating’ (Hill & Carter 1941).

Conservation IUCN Category: Least Concern.

The limited number of records and rarity of specimens are causes for concern. In Angola, there are many seemingly suitable localities where the species has not been encountered (Crawford-Cabral 1998). Eaten by local people (Sanborn 1952).

Mus goundae GOUNDA RIVER PYGMY MOUSE

Fr. Souris naine de la Gounda; Ger. Gounda-Fluss Zwergmaus

Mus goundae Petter and Genest, 1970. Mammalia 34: 455. Gounda River, N Central African Republic.

Taxonomy Subgenus *Nannomys*. Related to *M. oubanguii*. Synonyms: none. Chromosome number: 2n = 16–19, FN = 30; chromosomal polymorphism caused by Robertsonian translocations (Jotterand 1970, 1972).

Description Very small brownish-orange mouse, with pure white ventral pelage. Dorsal pelage ochraceous-brown, with orange-rufous on flanks. Ventral pelage pure white. Colour of dorsal pelage and ventral pelage clearly delineated on lower flanks. Ears large, blackish, slightly pointed at tip. White postauricular patch present. Fore- and hindfeet comparatively large, white. Tail short (ca. 55% of HB). Skull: rostrum elongated; incisors slightly pro-odont, choanae V-shaped; anterior palatal foramina short (one tenth of M¹–M³), M¹

with prelobe and without accessory cusp; M³ small; M₁ with anterior lobe quadricuspidate. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

M. oubanguii. Similar size; dorsal pelage reddish-brown; large white postauricular patch; nipples 3 + 2 = 10; chromosome number: 2n = 28.

M. setulosus. Larger (HB: 81.8 [77–86] mm, T: 55.5 [52–59] mm, GLS: 21.1 [19.3–21.9]); dorsal pelage blackish-brown; no auricular patches; nipples not known; chromosome number: 2n = 36.

M. musculoides. Similar size; dorsal pelage golden-brown; no postauricular patch; nipples $2 + 2 = 8$; chromosome number: $2n = 25-32$ (polymorphic); common and widespread.

Distribution Endemic to Africa. Guinea Savanna BZ. Only known from near the Gounda R., north-east of N'Délé, N Central African Republic.

Habitat Wooded savanna.

Abundance No information; known only from the type locality.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

The single known population is very small, and the number of individuals is probably declining.

Mus haussa HAUSA PYGMY MOUSE

Fr. Souris naine Haussa; Ger. Haussa Zwergmaus

Mus haussa (Thomas and Hinton, 1920). Novit. Zool. 27: 319. Farniso, near Kano, N Nigeria.

Taxonomy Originally described in the genus *Leggada*. Subgenus *Nannomys*. Morphologically and ecologically similar to *M. tenellus* (Rosevear 1969, Musser & Carleton 2005). Synonyms: none. Chromosome number: $2n = 28-34$, $FN = 38$ (Jotterand 1972, Veyrunes 2002, Granjon & Dobigny 2003).

Description Very small pale-coloured mouse; the smallest species of *Mus* in sub-Saharan Africa. Dorsal pelage pale sandy. Ventral pelage pure white. Colour of dorsal pelage and ventral pelage clearly delineated on flanks. Ears sandy-grey, with small whitish or sandy hairs. No postauricular patch of white hairs. Cheeks, lips and throat white. Fore- and hindfeet white. Tail short (ca. 75% of HB), scaly, pale or white, more or less naked. Skull: GLS 17 mm or less (cf. *M. minutoides*); upper incisors opisthodont, choanae U-V shaped, anterior palatal foramina elongated; M^1 elongated and 65–70% of M^1-M^3 ; M_1 with anterior lobe tricuspidate. Nipples: $3 + 2 = 10$.

Geographic Variation None recorded.

Similar Species

M. mattheyi. On average slightly larger (HB: 52 [46–60] mm); dorsal

pelage ochre-tawny to chestnut; parapatric.

M. musculoides. Larger (HB: 61 [55–70] mm, GLS: 18.4 [17.8–18.9] mm); dorsal pelage darker, golden-brown flecked with dark brown; distribution in less arid habitats.

Distribution Endemic to Africa. Sahel and Sudan Savanna BZs from Senegal to Chad and Sudan.

Habitat Semi-arid grassland savanna of the sub-Sahara region.

Abundance Evidence from remains in owl pellets (from Senegal, Nigeria and Chad) suggest this species may be locally common (see below).

Remarks Nocturnal and terrestrial. Tolerates the hottest and driest climates of all species of pygmy mice. Diet is seeds and insects (no detailed studies). Remains found in owl pellets in W Senegal (F. Petter unpubl.), Mali (Meinig 2000) and N Nigeria where they formed 13% of the rodent prey (Demeter 1978).

Conservation IUCN Category: Least Concern.

Mus indutus DESERT PYGMY MOUSE

Fr. Souris naine du désert; Ger. Wüstenzwergmaus

Mus indutus (Thomas, 1910). Ann. Mag. Nat. Hist., ser. 8, 5: 89. Molopo River, South Africa.

Taxonomy Originally described as *Leggada bella induta*. Subgenus *Nannomys*. Formerly considered as a subspecies of *M. minutoides*. Currently, *indutus* refers to *Mus* from the western parts of southern Africa, but the limits of its distribution are not known. Synonyms: *deserti*, *pretoriae*, *valschensis*. Subspecies: two or three. Chromosome number: 2n = 36, FN = 36–37 (Matthey 1966a, Veyrunes *et al.* 2004).

Description Very small mouse with soft pelage. Dorsal pelage variable shades of pale buff or pale buffy-orange; hairs slate-grey at base, some with black tip giving a grizzled appearance. Flanks buffy-orange without black-tipped hairs. Ventral pelage (including chin) pure white. Clear delineation between colour of flanks and ventral pelage. Head with pointed nose and long vibrissae. Ears moderately sized and rounded, brownish; small white subauricular patch (usually absent in eastern part of distribution). Limbs short with whitish feet; four digits on forefeet; five digits on hindfeet. Digits 3 to 4 elongated on both forefeet and hindfeet. All digits with well-developed claws. Tail long (ca. 80% of HB), pale buff above, white below. Nipples: 2 + 2 = 8.

Geographic Variation

M. i. indutus: Botswana and Namibia. Dorsal pelage comparatively pale buff.

M. i. pretoriae/valschensis: Gauteng Province, South Africa. Dorsal pelage tawny ochraceous-buff, reminiscent of *Mus minutoides*.

Similar Species

M. minutoides. Dorsal pelage generally darker, tail dark above; allopatric.

Mus indutus

M. setzeri. Ears longer; white ventral pelage extends onto upper rump and muzzle; sympatric.

Distribution Endemic to Africa. Zambezian Woodland and South-West Arid (Kalahari Desert) BZs. Recorded from C and

N Namibia (Matson & Blood 1994), through Botswana to NW South Africa and W Zimbabwe. Extends northwards into S Angola (Crawford-Cabral 1998) and SW Zambia (Ansell 1978).

Habitat Tolerates a wide range of habitats in semi-arid savannas (Nel 1978); avoids open micro-habitats (Kerley *et al.* 1990).

Abundance Abundant to very abundant. May undergo population explosions during periods of high food supply (Smithers 1971). In the Kalahari Desert of South Africa, *M. indutus* is the third most abundant species of small mammal after *Rhabdomys pumilio* and *Gerbillurus paeba* (Nel 1978).

Adaptations Nocturnal and terrestrial. Excavates its own burrows in sandy soil, but also uses burrows excavated by other species; may hide under rocks, fallen logs or beneath the bark of trees. Spherical nests are constructed underground from grass or other soft fibres, in which young are born.

Foraging and Food Diet is predominantly grass seeds and pods of *Acacia* trees, but includes insects (Smithers 1971, Nel 1978). Green plant material may also be important (Kerley *et al.* 1990).

Social and Reproductive Behaviour Highly aggressive towards conspecifics, with cases of cannibalism reported in captivity (Skinner & Smithers 1990). Such aggressive behaviour suggests territoriality, but critical studies are lacking. Offspring remain with both parents until they are weaned.

Reproduction and Population Structure May breed throughout the year, but peaks in pregnancy are recorded in Botswana during the wet season (Oct–Apr; Smithers 1971). Embryo number: 4.9 (2–8, $n = 17$; Botswana; Smithers 1971). Population explosions in *M. indutus* occur at the same time as those of *Mastomys natalensis*. High numbers of *M. natalensis* may possibly provide predator cover for *M. indutus*.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.
Widespread and abundant throughout its range.

Mus mahomet MAHOMET PYGMY MOUSE

Fr. Souris naine de Mahomet; Ger. Mohammed-Zwergmaus

Mus mahomet Rhoads, 1896. Proc. Acad. Nat. Sci., Philadelphia 1896: 532. Sheik Mahomet, Ethiopia.

Taxonomy Subgenus *Nannomys*. Within Ethiopia, *M. mahomet* is a distinctive species. The name *kerensis* Heuglin 1877 might be a prior name (Yalden *et al.* 1976). The status of this taxon is uncertain, and it may belong to another species from further south in Africa, such as *M. minutoides*, *M. bufo*, *M. sorella* or *bella* (synonym of *M. minutoides*) (Yalden & Largen 1992). Synonyms: *emesi*. Subspecies: none. Chromosome number: $2n = 36$, $aFN = 34$ (Aniskin *et al.* 1998).

Description Very small mouse, similar to *M. minutoides*. Pelage dense, short and slightly coarse. Dorsal pelage dark greyish-brown, slightly speckled with buff; hairs grey at base, brown or buff at tip. Ventral pelage greyish-white, sometimes with pale orange tinge; hairs grey at base, off-white at tip. Ventral pelage clearly delineated from flanks usually by thin orange-buff or sandy-yellow line. Ears darkly pigmented, prominent, covered with sparse short buffy hairs. No postauricular or subauricular white patches. Fore- and hindfeet white. Tail short (ca. 74% of HB), scaly, with many very short hairs; dark above, slightly paler below. Nipples: $3 + 2 = 10$.

Geographic Variation None recorded.

Similar Species

M. tenellus. Mostly smaller; dorsal pelage pale sandy-brown, ventral pelage pure white; white postauricular and/or subauricular patches; in Ethiopia, < ca. 2000 m).

M. triton. On average larger, dorsal pelage olive-brown; ventral pelage grey or whitish-grey; in Ethiopia, SE forests only.

M. musculoides. Similar size; sympatric in Uganda and Kenya.

M. setulosus. Slightly larger; dorsal pelage grey, ventral pelage pure white; sympatric or parapatric in Ethiopia; in Ethiopia, 1000–1500 m.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of Ethiopia and Eritrea; perhaps confined to the plateaux at 1500–3200 m (Yalden & Largen 1992). Considered by Musser & Carleton (1993, 2005) to occur also in SW Kenya and SW Uganda (not mapped). Limits unknown.

Habitat Upland forest-edges, scrub and grasslands, habitats partly shared with *Stenocephalemys albipes*, but unlike *S. albipes*, *M. mahomet* is not a true forest species (Yalden 1988, Yalden & Largen 1992).

Abundance Moderately common and widespread at middle altitudes in Ethiopia. Comprised 11% (n = 285) of rodents caught in Menagesha State Forest (Afework Bekele 1996a), and 6% (n = 905) in a wide range of sites in S Ethiopia (Rupp 1980).

Remarks Little is known about the biology of this species. Nocturnal and presumed to feed on seeds and insects. Parous ♀♀, and ♂♂ with enlarged testes, were trapped in Aug in Bale, Ethiopia, and a lactating ♀ was recorded in Jan at Illubabor, Ethiopia (1500 m; BMNH).

Conservation IUCN Category: Least Concern.

Mus mattheyi MATTHEY'S PYGMY MOUSE

Fr. Souris naine de Matthey; Ger. Mattheys Zwergmaus

Mus mattheyi Petter, 1969. Mammalia 33: 118. Accra, Ghana.

Taxonomy Subgenus *Nannomys*. Closely related to *M. haussa*. Musser & Carlton (1993, 2005) comment that they were 'unable to assign anything to *mattheyi* [and] the morphological traits used to distinguish *mattheyi* from *haussa* by Petter (1969) and by Petter & Matthey (1975) vary in a continuous fashion from typical *haussa* morphology to that considered diagnostic for *mattheyi*'. However, Veyrunes (2002) showed that *M. mattheyi* must be considered as a valid species because of its very high molecular divergence and chromosomal differences compared with *M. haussa*. Synonyms: none. Chromosome number: 2n = 36, FN = 36. The karyotype is considered to be ancestral for African *Mus* (Jotterand-Bellomo 1986).

Description Very small mouse, on average larger than *M. haussa* but on average smaller than *M. musculoides*. Dorsal pelage ochre-tawny to chestnut, usually darker along mid-dorsal line. Flanks fawn. Ventral pelage white. Colour of dorsal pelage and ventral pelage clearly delineated on flanks. Ears grey; no postauricular white patch. Fore- and hindfeet white. Tail short (ca. 70% of HB). Skull: upper incisors opisthodont; choanae V-shaped, sometimes tending to U-shaped (as in *M. haussa*); anterior palatal foramina elongated (but less than in *M. haussa*) reaching to level of posterior end of M¹; M¹ with prelobe; M₁ with anterior lobe tricuspidate. Nipples 2 + 2 = 8.

Mus mattheyi

Geographic Variation None recorded.

Similar Species

M. haussa. On average slightly smaller (HB: 49.7 [44–52] mm, HF: 12 [11.5–12.5] mm, GLS: 16.6 [15–17] mm); dorsal pelage pale sandy; distribution in more arid habitats.

M. musculoides. On average larger (HB: 61 [55–70] mm, HF: 13.6 [12–14] mm, GLS: 18.4 [17.8–18.9] mm); dorsal pelage darker, golden-brown flecked with dark brown; sympatric.

Distribution Endemic to Africa. Sudan Savanna and Guinea Savanna BZs. Recorded from Senegal to Côte d'Ivoire (and perhaps Togo), and Burkina (Veyrunes 2002), but distribution may be more extensive. Musser & Carleton (2005) record only from the type locality (see above). Geographic range is further south than for *M. haussa*.

Habitat Moist woodland savanna and grass savanna. The holotype was taken on the Accra plain.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Mus minutoides TINY PYGMY MOUSE

Fr. Souris naine d'Afrique australe; Ger. Kleine Zwergmaus

Mus minutoides Smith, 1834. S. Afr. Quart. J., ser. 2, 2: 157. Cape Town, South Africa.

Taxonomy Subgenus *Nannomys*. Taxonomic status of this species is uncertain. Formerly, *M. indutus* and *M. orangiae* were considered subspecies of *M. minutoides*, but are now regarded as valid species (Musser & Carleton 1993, 2005). Currently, *minutoides* refers to *Mus* from the eastern side of Africa, from East Africa to South Africa, but the limits of the geographic range are uncertain. If *M. musculoides* is included in *M. minutoides* (as in Musser & Carleton 2005), then *M. minutoides* has a distribution throughout much of the savanna regions of Africa. The *minutoides*–*musculoides* complex and the relationship between *M. minutoides* and *M. musculoides* is not yet resolved. Diploid chromosome number apparently variable, suggesting *minutoides* may include sibling species. Synonyms: *kasaicus*, *marica*, *minimus*, *umbratus*. Subspecies: three, validity uncertain. Chromosome numbers: 2n = 18, FN = 36 (Western Cape Province, South Africa); 2n = 34 (KwaZulu–Natal, South Africa) (Matthey 1966a, Skinner & Smithers 1990, Veyrunes *et al.* 2004).

Description Very small mouse with soft, shiny pelage. Dorsal pelage variable shades of brownish-buff to brownish-orange; hairs slate-grey at base with black tip. Flanks buffy-orange. Ventral pelage (including chin) pure white. Clear delineation between colour of flanks and ventral pelage. Head with pointed nose and long vibrissae. Ears brownish, moderately sized and rounded. Limbs short. Feet white with well-developed digits; four digits on forefoot; five digits on hindfoot. Digits 2–4 elongated. All digits with well-developed claws. Tail short (ca. 75% of HB), brownish above, paler below. Nipples: 3 + 2 = 10.

Geographic Variation Meester *et al.* (1986) list three subspecies for southern Africa:

M. m. minutoides: Western Cape, Eastern Cape and KwaZulu–Natal Provinces, South Africa.

M. m. umbratus: Swaziland and NE South Africa.

M. m. marica: E Mpumalanga Province, South Africa; S Mozambique.

Specimens from Western and Eastern Cape Provinces (South Africa) are slightly darker than specimens from KwaZulu–Natal and E Mpumalanga Provinces (South Africa), Swaziland and S Mozambique. Differences, however, not very noticeable due to great variation within each region. Specimens from S Mozambique have fewer black-tipped hairs in dorsal pelage, resulting in brighter brownish-orange colour (but highly variable).

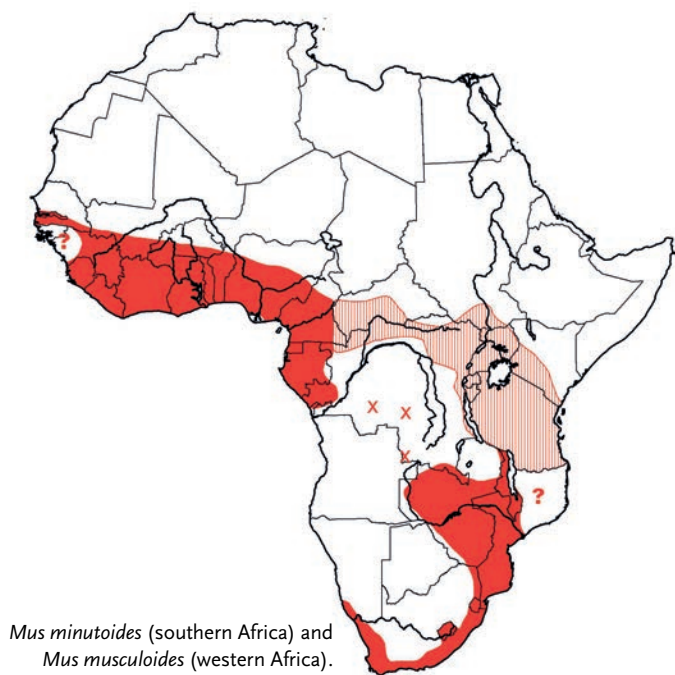

Similar Species

M. indutus. Dorsal pelage generally paler; tail pale above.

M. setzeri. Ears longer; white ventral pelage extends on to upper rump and muzzle.

Distribution Endemic to Africa. Zambezan Woodland BZ (eastern part), South-West Cape BZ and southern Somalia–Masai Bushland BZ. Also occurs at higher altitudes in Swaziland. Recorded in S and E South Africa, northwards through Swaziland and S Mozambique to Zimbabwe and Malawi. Two isolated records from NE Namibia (Matson & Blood 1994). Northern limit of the geographic range where it adjoins that of *M. musculoides* in eastern Africa is uncertain (shown by striped lines on map). Replaced by *M. indutus* in western part of Zambezan Woodland BZ.

Habitat Tolerates a wide range of habitats. In Swaziland, occurs in afro-montane and riparian forests, short to tall grasslands, rocky outcrops, all forms of *Acacia* and broad-leaved woodland, cultivated

Mus minutoides (southern Africa) and
Mus musculoides (western Africa).
See also text.

fields and recently burnt areas (Monadjem 1998a). May also occur in suburban gardens, young pine plantations and on the fringe of wetlands. Altitude range: near sea level to 2700 m (Rowe-Rowe & Meester 1982a).

Abundance Abundant to very abundant. Densities of up to 28/ha have been recorded (Monadjem 1998b), and presumably may reach much higher densities during favourable conditions.

Adaptations Nocturnal and terrestrial. Tiny Pygmy Mice excavate their own burrows in soft soil, and will also use holes excavated by other species, or will rest under rocks, fallen logs or beneath the

bark of trees. During the non-breeding season, shelters may be changed regularly. Construct spherical nests, under cover, from grass or other soft fibres in which young are born. In captivity, does not enter spontaneous torpor at low temperatures or during periods of reduced food availability (Webb & Skinner 1995, Downs & Perrin 1996).

Foraging and Food Omnivorous. Diet consists mostly of grass seeds and insects (Rowe-Rowe 1986), but foliage predominates in the Karoo of SW South Africa (Kerley 1992). Proportional contribution of food types in stomach contents: 44% vegetable material, 40% seeds, 16% arthropods (n = 17, Swaziland; Monadjem 1997b).

Social and Reproductive Behaviour Reported to forage independently, but frequently pairs are captured in the same live-trap, suggesting that they may forage together (Monadjem 1998a). In Swaziland, mean distance between successive monthly captures (on a 1 ha grid) was 18.6 m, indicating that movements are limited to a small area. In captivity, copulation is preceded by grooming of ♀ by her mate (Willan & Meester 1978). Females aggressively defend their nests when young are present. Self-grooming commences at 10–11 days of age and continues through adulthood.

Reproduction and Population Structure Poorly known for such an abundant species. Reproduction peaks in the wet season (Nov–Feb) but may continue throughout the year. Mean litter-size 4.5 (n = 4, KwaZulu–Natal, South Africa; Taylor 1998) and 4.0 (range 1–7, n = 27, in captivity; Willan & Meester 1978). Gestation (in captivity): 18–19 days. At birth, young hairless, weight 0.8 g. Incisors erupt Day 7–9. Young weaned Day 18. Sexual maturity attained Day 42 (Willan & Meester 1978). Mean interval between litters 22 days. Population numbers fluctuate widely at some localities (Monadjem 1999b) but not at others (Monadjem 1998b). Survival rates are low and few individuals live to one year of age. Sex ratio does not deviate from parity (Monadjem 1999b).

Mus minutoides.

Predators, Parasites and Diseases Preyed upon by several species of owls (Vernon 1972, Perrin 1982). Ectoparasites include 12 species of fleas, and three species of ticks (details in De Graaff 1981). Susceptible to plague in laboratory conditions.

Conservation IUCN Category: Least Concern.
Widespread and abundant throughout its range.

Mus musculoides WEST AFRICAN PYGMY MOUSE

Fr. Souris naine d'Afrique de l'Ouest; Ger. Westafrikanische Zwergmaus

Mus musculoides Temminck, 1853. Esquisses Zool. sur la Côte de Guinée, p. 161. 'Côte de Guinée', West Africa. Exact locality uncertain.

Taxonomy Subgenus *Nannomys*. The taxonomic relationship of this species with *M. minutoides* of eastern and southern Africa is uncertain. Within West Africa, this species has been referred to both *M. musculoides* and *M. minutoides*. The taxon *musculoides* has been placed as a subspecies of *M. minutoides* (Petter & Matthey 1975), as a valid species (Rosevear 1969, Happold 1987, Musser & Carleton 1993, Grubb *et al.* 1998), or placed in synonymy with *L. minutoides* (Musser & Carleton 2005). The species occurs throughout West Africa; however, its eastern geographic border is uncertain (see Distribution); Musser & Carleton (1993) consider this to be Ethiopia and Somalia, but R. Hutterer (pers. comm.) places the eastern limit as W Cameroon. Hence the identity of C African populations is questionable. Rosevear (1969) placed *Mus musculoides* in the subgenus *Leggada*, now a synonym of *Nannomys* (Musser & Carleton 1993). See also *Mus minutoides* for

further comment. Synonyms: *bella* (or *bellus*), *enclavae*, *gallarum*, *gondokorae*, *grata*, *marica*, *paulina*, *petila*, *soricoides*, *sungarae*, *sybilla*, *vicini* (Musser & Carleton 1993). Subspecies: none. Chromosome number shows Robertsonian polymorphism: at Ippy, Central African Republic, 2n = 25 to 2n = 32, with 2n = 28 and 2n = 29 forming about 60% of population (n = 31); another study at Ippy, 2n = 38, FN = 33 and 34 (n = 4) (Jotterand-Bellomo 1984); in Côte d'Ivoire, 2n = 33 (n = 6) and 2n = 33 (n = 2) (Jotterand-Bellomo 1984); in S Nigeria, 2n = 32 (n = 1), 2n = 33 (n = 4) and 2n = 34 (n = 7) (R. Matthey pers. comm.); in Mali, 2n = 18 (♀ ♀), 2n = 19 (♂ ♂) (n = 8) (Veyrunes *et al.* 2004).

Description Very small delicate mouse with short tail and white ventral pelage. Dorsal pelage golden-brown, flecked with dark brown; hairs pale grey at base, golden-brown at tip. Flanks similar in colour to dorsal pelage, becoming paler on lower flanks. Head similar in colour to dorsal pelage; small white subauricular patch. Ventral pelage pure white. Colour of flanks and ventral pelage clearly delineated. Chin, chest, fore- and hindlimbs white. Tail short (ca. 70% of HB) and slender, pale brown above, whitish below. Total length of skull more than 17 mm (cf. *M. haussa*). Nipples 2 + 2 = 8.

Geographic Variation None except in karyotype (see Taxonomy).

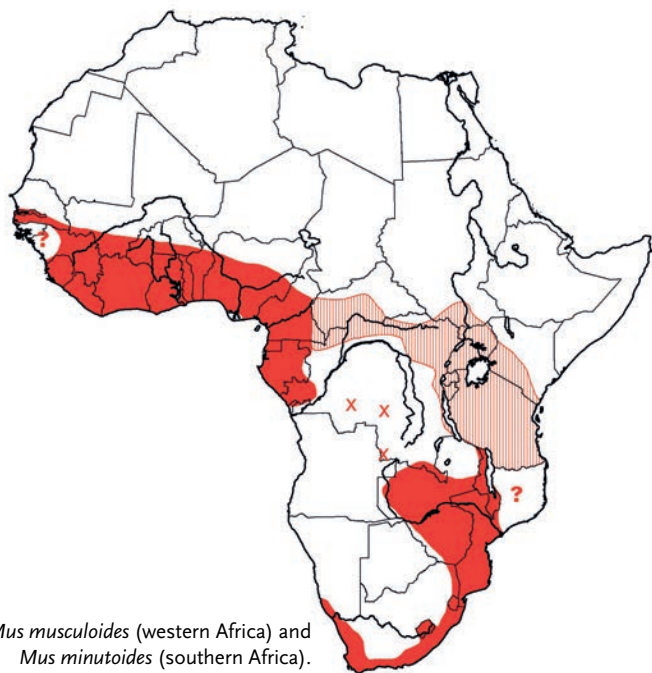

Similar Species

M. setulosus. Larger (HB: 81.8 [77–86] mm, HF: 14.1 [14–16] mm, M¹–M³: 3.58 [3.5–3.6] mm); dorsal pelage darker.

M. haussa. On average smaller (HB: 49.7 [44–52] mm, HF: 12 [11.5–12.5] mm, M¹–M³: 2.9 [2.9–3.1] mm); dorsal pelage paler; distribution further north, mostly in Sudan and Sahel Savanna BZs.

M. mattheyi. On average smaller (HB: 52 [46–60] mm, HF: 12 [11.5–12.5] mm, M¹–M³: 2.9 [2.9–3.1] mm); Ghana, distribution limits and status uncertain.

Distribution Endemic to Africa. Widely distributed in Guinea Savanna BZ, Northern Rainforest–Savanna Mosaic, and grassy patches in Rainforest BZ. May extend into southern parts of Sahel Savanna

Mus musculoides (western Africa) and
Mus minutoides (southern Africa).
See also text.

BZ in west of range. Recorded from Gambia and Senegal to Cameroon, and may extend further eastwards through N DR Congo, Central African Republic and Uganda to Ethiopia and Somalia (see above). Western extension of range to East Africa, and where *M. minutoides* replaces *M. musculoides*, also uncertain (shown by striped lines on map). Geographic range has extended southwards into 'savanna-like' habitats within the Rainforest BZ in recent years as a result of human-induced activities (clearing of rainforest, farming, urbanization).

Habitat Savanna woodlands and grasslands, as well as new and old farmlands, secondary bush and immature cocoa plantations. Grassy areas within Rainforest BZ, such as road verges, farmlands and clearings. Does not occur in rainforest except, very occasionally, in natural grassy clearings where trees have fallen.

Abundance At 14 widely separated savanna habitats in W Nigeria, comprised on average 14% (0–53%) of captured small rodents (Happold 1975b), and at Olokomeji F. R. (in Rainforest–Savanna Mosaic) they formed 56% of all small rodents in grasslands at certain times of year (Anadu 1973). Relative abundance (and absolute numbers) declines from south to north in W Nigeria from 90% in Rainforest–Savanna Mosaic to 11–41% in southern Guinea Savanna BZ and (usually) 0% in northern Guinea Savanna BZ (where *Tatera kemp* [now *Gerbilliscus kemp*], *Myomys daltoni* [now *Praomys daltoni*] and *Mastomys* spp. are common species) (Happold 1975b). In natural clearings in rainforest in Ghana they comprise ca. 2% of small rodents, the fifth most numerous species after *Lophuromys sikapusi*, *Praomys tullbergi*, *Dephomys defua* and *Hybomys trivirgatus* (Jeffrey 1977).

Population numbers vary seasonally and annually in W Nigeria (Anadu 1973). Numbers tended to be lowest at the end of the wet season (Oct/Nov), increasing during the dry season and early wet season, and declining gradually during the late wet season. Density: 2–4/ha (end of wet season) to 7–10/ha (end of dry season). In some years, highest density is 23–35/ha (early dry season).

Adaptations Terrestrial and nocturnal. Construct spherical or cup-shaped nests of shredded grass under logs and in shallow burrows. Locomotion is a rapid scuttle; when disturbed, individuals hide under logs, dry grass and any other available cover. Numbers decline markedly where savanna is burned during dry season (probably mostly due to emigration), but immigrants from unburnt areas return as soon as grasses sprout again (Anadu 1973).

Foraging and Food Herbivorous. In captivity, feeds on small seeds, grass stems and fruits.

Social and Reproductive Behaviour Gregarious. In captivity,

many individuals huddle together in a nest; huddling is probably an important aspect of thermoregulation in this small species, especially during cooler days of the dry season.

Reproduction and Population Structure Reproduction is seasonal in S Nigeria. Young born Aug–May; most litters at end of dry season and beginning of wet season (Mar–Apr), and at end of wet season (Sep–Dec). Embryo number (wild-caught ♀♀): 3.38 (2–6, mode 2, n = 13); embryo number (captive ♀♀): 3.00 (1–5, mode 3, n = 18 litters from seven ♀♀; Anadu 1976). Females may have several litters in close succession. Gestation: 22–24 days. Litter interval (in captivity): 41–58 days. At birth, young are naked, eyes are closed, and mean WT = 0.8 g. External ear open Day 11. Eyes open Day 14. Weaned at Day 24. Almost (92%) adult HB length by Day 30; adult size by Day 60. Sexual maturity 10–12 weeks. Longevity: probably not longer than ca. one year. Mice born at beginning of wet season (Apr) attain sexual maturity during the wet season and begin to breed in Aug; mice born at end of wet season (Nov–Dec) are not mature until the beginning of next breeding season in Mar–Apr. Hence continual recruitment of young throughout most of year, and high annual turnover (Anadu 1973). No details from other parts of range.

Predators, Parasites and Diseases Preyed upon by owls. Second most numerous species in pellets of Barn Owls *Tyto alba* on Mt Nimba, Liberia (Heim de Balsac & Lamotte 1958). In N Nigeria, comprised 4–8% of prey numbers (total n = 64) in pellets of Barn Owls and 3% of prey numbers (total n = 83) in pellets of Spotted Eagle-owls *Bubo africanus* (Demeter 1981).

Conservation IUCN Category: Least Concern (as *M. minutoides*). Widespread and not threatened.

Mus musculus HOUSE MOUSE

Fr. Souris domestique; Ger. Haus-Maus

Mus musculus Linnaeus, 1758. Syst. Nat., 10th edn., 1: 62. Uppsala, Sweden.

Taxonomy Subgenus *Mus*. Many forms or subspecies of *Mus musculus* have been described, most of which are now considered as synonyms (see Musser & Carleton 1993, 2005) although others

may be species (Marshall & Sage 1981). The taxonomy of the 'house mouse' has been less well studied in Africa than elsewhere (but see Granjon *et al.* 1992, Prager *et al.* 1998). Recent research suggests

that the 'correct' name of the domestic mouse is likely to be *Mus domesticus* (Boursot *et al.* 1993, 1996, Din *et al.* 1996, Prager *et al.* 1998). One taxon (*M. spretus* of North Africa and S Europe), originally included in *Mus musculus*, is now considered to be a valid species. Traditionally, there appear to be two forms of *Mus musculus*: a domestic form (which lives only in houses and has a relatively longer tail) and a feral form (which lives in human-modified habitats and has a relatively shorter tail). Synonyms that refer to Africa include *brevirostris*, *domesticus*, *gentilis*, *praetextus*, *vignaudi* (all pale-bellied forms from North Africa – see Osborn & Helmy 1980, Aulagnier & Thévenot 1986) and *modestus* (dark-bellied form from southern Africa (see Meester *et al.* 1986). Musser & Carleton (2005) provide a full list of synonyms. Chromosome number: $2n = 40$, $FN = 38$ (Niger: Dobigny *et al.* 2002b; Senegal: Granjon *et al.* 1992); $2n = 22$ (Robertsonian populations in Tunisia; Said & Britton-Davidian 1991).

Description Very small greyish mouse, normally associated with houses. Dorsal pelage greyish or brownish-grey; hairs dark grey at base, pale grey or brown at terminal end, sometimes with black tip. Flanks paler. Ventral pelage buffy-brown, pale grey, or white, merging into colouration of flanks. Head rather pointed, dark 'beady' eyes; ears large, mostly naked. Fore- and hindlimbs short, greyish, with small naked unpigmented digits. Tail long (ca. 90–100% of HB), thin, almost naked, slightly darker above than below. Nipples: $3 + 2 = 10$.

Geographic Variation Throughout its range, *M. musculus* shows large differences in colour and pattern. For Africa, the following forms may be recognized:

gentilis (including *praetextus*): North Africa, Sudan, Ethiopia. Pale (usually white) ventral pelage.

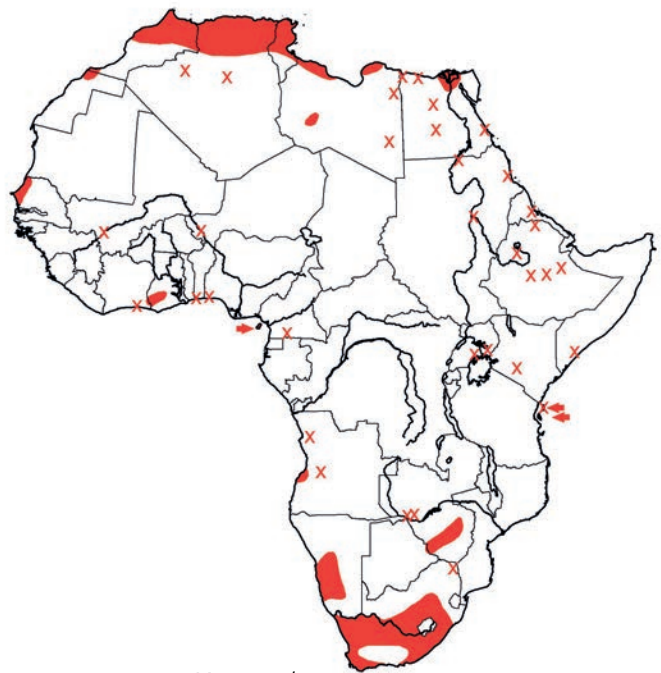

modestus (? *domesticus*): North Africa; South Africa (and perhaps Namibia and Zimbabwe). Buffy-brown or grey ventral pelage.

In North Africa, both dark and pale-bellied forms are usually distributed in a geographical mosaic in separate farms and oases (Marshall & Sage 1981).

Similar Species

Mus (Nannomys) spp. On average smaller body size; tail relatively shorter (i.e. usually less than 75% of HB); natural habitats (Table 37).

Distribution Not indigenous to Africa. Occurs in most countries of the world, but not widespread in Africa. Recorded in temperate Africa, especially in the northern parts of Morocco, Algeria, Libya and Tunisia, and in the Nile Valley. In Algeria and Libya, known from some oases in the desert. Occurs up to 2000 m in the High Atlas of Morocco. Introduced to sub-Saharan Africa by Arab and European shipping, but has formed permanent populations only in selected localities in South Africa (including Marion I.), Namibia, Zimbabwe and Senegal (north of Dakar). Mostly rare in tropical Africa, and recorded from only a few localities near the coastline where populations may not be permanent. Of the three species of small murid rodents introduced into Africa, *M. musculus* has not colonized the continent to the same extent as *Rattus rattus* but has been more successful than *R. norvegicus*.

Mus musculus

Habitat In Africa, mostly commensal and confined to houses, food stores and other urban buildings, although a few populations are feral (e.g. in Morocco [Aulagnier & Thévenot 1986], Algeria [Kowalski & Rzebik-Kowalska 1991] and southern Africa [Smithers 1983]). In Libya, recorded as commensal and quite widely distributed in the wild where the habitat is mesic and has a dense cover of plants (Ranck 1968). In Egypt, also found in a variety of natural habitats including gardens, barley fields, sand flats, salty waste land (with *Suaeda* and other halophytic plants), canal banks and palm groves (Osborn & Helmy 1980). In N Sudan, recorded only from Khartoum during winter months, but not in villages away from the Nile R. (Happold 1967c). In Senegal, House Mice are strictly commensal (J.-M. Duplantier, unpubl.).

Abundance In North Africa, may be fairly abundant in suitable habitats when conditions are optimal. Little information for Africa south of the Sahara; Smithers (1983) records that, in southern Africa, House Mice never occur in sufficient numbers to become a major problem, a contrasting situation to temperate regions of the world, and to some countries where they have been introduced, where they may be major pests, e.g. Australia.

Adaptations Nocturnal and diurnal; terrestrial and scansorial. Extreme adaptability with respect to food and climate has enabled House Mice to colonize many habitats in most parts of the world. Most populations are commensal, some are feral. House Mice require adequate water (as free water or in food) and hence do not survive in arid habitats (unless close to a river, a man-made water supply, or in oases). Nevertheless, in Senegal, they live in drier areas than *Rattus rattus*. Populations are able to breed (and remain viable) in a wide range of climates where the ambient temperatures are very high (as in hot deserts) or very low (sub-Antarctic islands). Rapid reproduction (see below) enables populations to increase rapidly when environmental conditions are good.

Foraging and Food Omnivorous. Primarily granivorous and herbivorous, but will feed on anything edible. Occasionally feed on insects and earthworms.

Social and Reproductive Behaviour Communal and sociable. In established groups, ♂♂ defend an area of variable size (which is related to food availability). When populations are low, any increase in resources promotes rapid reproduction; when populations are high, reproductive rate declines, and at very high densities and when food is limiting, reproduction may cease completely. House Mice are good colonizers, and in a very short period of time can become very numerous (Corbet & Southern 1977).

Reproduction and Population Structure Little information for Africa. Very prolific. In Egypt, pregnant ♀♀ and nestling young present throughout year (Osborn & Helmy 1980). Typically, in other parts of the world, ♀♀ may produce 5–10 litters/year. Gestation: 19–20 days; fertilization may occur during postpartum oestrus. Litter-size: ca. 5.5 (4–8). Young weaned by Day 20. Sexual maturity when 7.5 g (♀♀) to 10 g (♂♂) (Corbet & Southern 1977). Rapid reproduction maintains high population numbers even when predation rates are high.

Predators, Parasites and Diseases Many small mammalian carnivores, birds of prey and snakes feed on House Mice. Ectoparasites include several species of fleas and a sucking louse. The fleas *Xenopsylla cheopis*, *X. ramesis*, *Pulex irritans*, *Nosopsyllus londiniensis* and *Synosternus cleopatrae* are commonly found on House Mice in Egypt (Hoogstraal

& Traub 1965b). Several human diseases can be carried by House Mice including tularaemia, leptospirosis, borreliosis and several *Salmonella*-like bacteria that cause food poisoning.

Conservation IUCN Category: Least Concern.

House Mice are major pests in some parts of the world, and control of their populations is essential. They eat and contaminate stored foods, and are a threat to public health in many parts of the world. The domestic white mouse, used extensively for medical research, is derived from this species.

Mus neavei NEAVE'S PYGMY MOUSE

Fr. Souris naine de Neave; Ger. Neaves Zwergmaus

Mus neavei (Thomas, 1910). Ann. Mag. Nat. Hist., ser. 8, 5: 90. Petauke, Loangwe district, E Zambia. 2500 ft (762 m).

Taxonomy Originally described in the genus *Leggada*. Subgenus *Nannomys*. Described as *Leggada neavei* (Thomas 1910a). Belongs to the 'sorella group' (see *Mus sorella*). Considered as a subspecies of *M. sorella* (Verheyen 1965b, Smithers 1983, Meester *et al.* 1986), although Petter (1981) suggested that it should be treated as a valid species. Relationship to *M. oubanguii* and *M. baoulei* is uncertain (Musser & Carleton 2005). Synonyms: none. Chromosome number: not known.

Description Small mouse with rich tawny pelage. Dorsal pelage ochraceous-brown to rich tawny-brown, tending to blackish on mid-dorsal region. Ventral pelage pure white. Colour of dorsal pelage and ventral pelage clearly delineated on lower flanks. Head with pointed muzzle. Ears large, pale grey. Fore- and hindfeet white. Tail short (ca. 43% of HB). Skull: rostrum elongated, incisors slightly pro-odont, choanae V-shaped; M¹ with small prelobe. Nipples: not known.

Geographic Variation None recorded.

Similar Species

M. sorella. Mean HB smaller; mean GLS larger; mean M¹–M³ longer; dorsal pelage dark greyish-brown.

Mus neavei

M. minutoides. Mean HB smaller (51.3 [45–63] mm); mean M^1 – M^3 slightly smaller (3.0 (2.8–3.2) mm); dorsal pelage brownish-buff (variable).

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded from S Tanzania, S DR Congo, SE Zambia, S Zimbabwe, W Mozambique and South Africa (former Transvaal). Limits of geographic range unknown. Records from Malawi represent other species (Ansell & Dowsett 1988).

Habitat Woodland savanna.

Remarks Apparently no other information on this species.

Conservation IUCN Category: Data Deficient.

Mus orangiae ORANGE PYGMY MOUSE

Fr. Souris naine d'Orange; Ger. Orange Zwergmaus

Mus orangiae (Roberts, 1926). Ann. Transvaal Mus. 11: 251. Viljoensdrift, near Vereeniging, Kruisementfontein, South Africa.

Taxonomy Originally described in the genus *Leggada*. Subgenus *Nannomys*. Formerly considered a subspecies of *Mus minutoides* (e.g. De Graaff 1981; Meester *et al.* 1986) but now considered as a valid species. Considered to be allied, on craniological grounds, to *Mus setzeri* (Vermeiren & Verheyen 1983). Synonyms: none. Chromosome number: not known.

Description Very small mouse with soft pelage. Dorsal pelage bright orange-buff; hairs with pale grey base; orange-buff at tip; black tips of some hairs result in a slightly grizzled appearance. Flanks orange-buff, without any black-tipped hairs. Ventral pelage pure white. Head with pointed nose and long vibrissae. Ears brownish,

relatively long and rounded; white subauricular patch (probably) absent. Limbs short with white feet and well-developed digits; four digits on forefeet; five digits on hindfeet. All digits with well-developed claws. Tail short (ca. 60% of HB), brownish above, paler below. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

M. minutoides. Similar size and shape; dorsal pelage reddish-brown with some black-tipped hairs; may differ craniologically; marginally parapatric.

M. indutus. On average slightly smaller; HF usually larger; dorsal pelage generally paler; tail pale above; marginally sympatric.

M. setzeri. Similar size; rump white; allopatric.

Distribution Endemic to Africa. Highveld BZ. Recorded from C South Africa and Lesotho. Taxonomic status of *Mus* occurring in the southern part of the Free State, South Africa, uncertain, but may represent *M. orangiae*. Limits of geographic range not known.

Habitat Lynch (1983, as *M. minutoides* but presumably referring to *M. orangiae*) records that in the Free State, specimens were mostly collected in short, open grassland.

Abundance 'Mus minutoides is not abundant in the Orange Free State' (Lynch 1983). No other information.

Remarks Nocturnal and terrestrial; constructs a grass nest amongst piles of rocks or in disused termitaria (Lynch 1983).

Conservation IUCN Category: Least Concern.

However, too little is known about this species to be able to assess its conservation status adequately.

Mus oubanguii OUBANGUI PYGMY MOUSE

Fr. Souris naine de l'Oubangui; Ger. Oubangui-Zwergmaus

Mus oubanguii Petter and Genest, 1970. Mammalia 34: 454. Bangassou near La Maboké (near Mongoumba), Central African Republic.

Taxonomy Subgenus *Nannomys*. Synonyms: none. Chromosome number: 2n = 28; FN variable; polymorphism is non-Robertsonian (Matthey & Jotterand 1970, Jotterand 1972, Jotterand-Bellomo 1984).

Description Very small reddish-brown mouse with pure white ventral pelage. Dorsal pelage reddish-brown. Ventral pelage pure white. Colour of dorsal pelage and ventral pelage clearly delineated on flanks. Head with pointed muzzle. Ears large, blackish, slightly pointed at tip. Large white postauricular patch. Fore- and hindfeet white. Hindfeet comparatively large (cf. *M. mattheyi*). Tail short (ca. 60% of HB). Skull: rostrum elongated; incisors orthodont or slightly pro-odont; choanae V-shaped; anterior palatal foramina short; M¹ and M² well developed, M³ small; M¹ with well-developed prelobe and without accessory cusp; M₁ with anterior lobe quadricuspidate. Nipples: 3 + 2 = 10.

Geographic Variation None recorded.

Similar Species

M. goundae. Similar size; dorsal pelage ochraceous-brown; nipples 2 + 2 = 8; chromosome number: 2n = 16–19; N Central African Republic.

M. musculoides. Similar size; dorsal pelage golden-brown; no postauricular patch; nipples 2 + 2 = 8; chromosome number: 2n = 25–32 (polymorphic); common and widespread.

M. setulosus. Much larger (HB: 81.8 [77–86] mm, T: 55.5 [52–59] mm); dorsal pelage blackish-brown; no auricular patches; chromosome number: 2n = 36; widespread.

Distribution Endemic to Africa. Northern Rainforest–Savanna Mosaic. Recorded only from the type locality at Bangassou near La Maboké, and at Ippy on the right bank of Oubangui R., SW Central African Republic.

Habitat Savanna patches on sandy slightly lateritic soil, close to rainforest, with grasses (mostly *Loudetia arundinacea*) and trees (mostly *Hymenocardia acida*, *Annona senegalensis*, *Lophira alata* and introduced *Borassus aethiopium*). Type locality (and study site – see Genest-Villard 1973) was an unburnt reserve. Sympatric with *M. setulosus* and *M. minutoides* (Petter & Genest 1970).

Abundance Uncertain. In suitable habitats, 10–25 burrows/100 m² (Genest-Villard 1973). Distribution is very localized.

Adaptations Nocturnal and terrestrial. During the day, rests in simple underground burrows. Burrows are up to ca. 60 cm in length, with a spherical nest chamber (ca. 20 cm diameter) and an escape entrance. The nest is lined with leaves of grass and trees. The main entrance is blocked with fragments of grass and dead leaves. Burrows may be constructed close of those of *Tatera* (now *Gerbilliscus*) spp. and occasionally the burrows of the two species join up (Genest-Villard 1973).

Foraging and Food Mainly granivorous. In captivity, eats seeds and small insects.

Mus oubanguii

Social and Reproductive Behaviour Normally nest alone, except when ♀ has her young. Adult ♂ nest alone.

Reproduction and Population Structure Litter-size: 4–5. Births recorded in May and Jun (no data for other months) (Genest-Villard 1973).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Data Deficient.

The very limited geographic range, isolation of populations and decline in habitat are cause for concern.

Mus setulosus PETERS'S PYGMY MOUSE

Fr. Souris naine de Peters; Ger. Peters Zwergmaus

Mus setulosus Peters, 1876. Monatsb K. Preuss. Akad. Wiss. Berlin: 480. Victoria, Cameroon.

Taxonomy Subgenus *Nannomys*. One form (*proconodon*) from Ethiopia was considered to be a valid endemic species by Yalden *et al.* (1976). Synonyms: *pasha*, *proconodon*. Subspecies: none. Chromosome number: 2n = 36, FN = 36 (Matthey 1966a, Jotterand-Bellomo 1986).

Description Small dark-coloured mouse; the largest of pygmy mice in West Africa. Pelage short, slightly coarse (cf. soft in other pygmy mice); comparatively long (7 mm). Dorsal pelage blackish-brown, usually 'dull', very finely speckled with buff (without the 'bright' russet colouration of *M. musculoides*); hairs grey at base, buff or black at tip. Lower flanks slightly paler, with fewer black-tipped hairs. Ventral pelage pure white or off-white. Head similar in colour to dorsal pelage. Ears darkly pigmented, with sparse short grey or buff hairs. Upper lips with narrow white fringe (not wide as in *M. haussa* or *M. musculoides*). Auricular patches absent. Fore- and hindfeet white. Tail short (ca. 67% of HB), dark above and below, with small scaly rings and scattered short dark bristles. Skull: larger than in other species of pygmy mice in West Africa (see also below); total length of skull ca. 21 mm; anterior palatal foramina 4.8 (4.4–5.1) mm; M² with small antero-external cusp (Rosevear 1969).

Geographic Variation Individuals from Cameroon (see Measurements) are larger than *proconodon* (see Taxonomy) from Ethiopia.

Similar Species

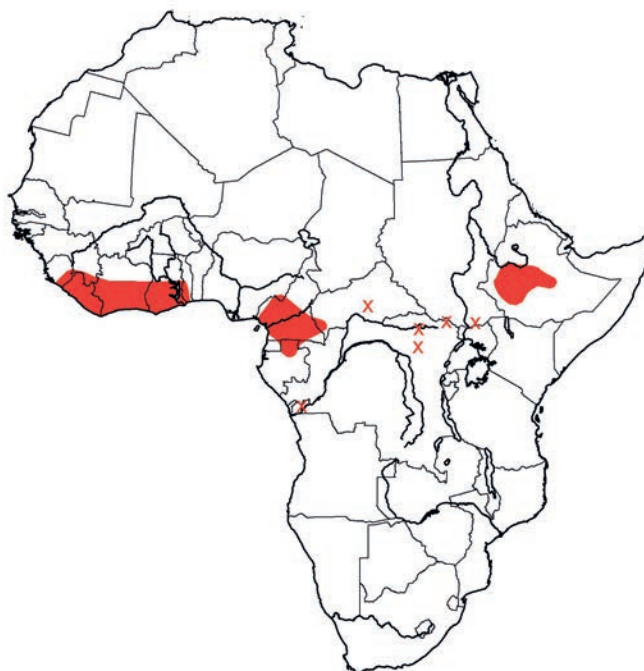

M. haussa. Smaller in most measurements; dorsal pelage sandy; auricular patches present; geographic range further north.

M. musculoides. Smaller; dorsal pelage buff or russet, usually rather bright; auricular patches present; sympatric.

Distribution Endemic to Africa. Rainforest BZ (Western and West Central Regions), Northern Rainforest–Savanna Mosaic and Afromontane–Afroalpine BZ of Ethiopia. Most locality records are from E Sierra Leone, Liberia, Côte d'Ivoire, Ghana and Togo; also

recorded from E Nigeria (Gotel Mts, Yelwa), S Cameroon (Adamaoua Mts, Victoria) and Gabon (Hutterer & Joger 1982, Hutterer *et al.* 1992, Grubb *et al.* 1998). Scattered localities in Central African Republic, NE DR Congo and S Sudan. Isolated populations in Ethiopia (as *proconodon*). Not recorded from Benin and S Nigeria, where perhaps it occurs. One locality in SE DR Congo (not mapped) needs verification.

Habitat Most records are from relict forests in the Rainforest BZ, and from gallery forests and grasslands in montane habitats, e.g. gallery forest (E Nigeria, Cameroon), montane grassland and gallery forest (Liberia), tropical deciduous forest and cultivated areas of cleared tropical forest (Ethiopia), and grassfields at edge of forest on

Mus setulosus

Mt Nimba (Guinea). Recorded from 1000 to 1750 m in Ethiopia (where it is considered a 'lowland species' – Yalden *et al.* 1976), at 1550–2300 m in highlands of Cameroon and Nigeria, and 500–1300 m on Mt Nimba, Liberia.

Abundance Generally uncommon, and not captured as often as sympatric *M. musculoides*. May be locally common, as in parts of S Cameroon (Eisentraut 1973).

Remarks There is no detailed biological information on this species. Rosevear (1969) suggested that it is probably very similar to *M. musculoides*.

Conservation IUCN Category: Least Concern.

Mus setzeri SETZER'S PYGMY MOUSE

Fr. Souris naine de Setzer; Ger. Setzers Zwergmaus

Mus setzeri Petter, 1978. Mammalia 42: 377. 82 km west of Mohembo, Botswana.

Taxonomy Subgenus *Nannomys*. Craniologically most similar to *Mus orangiae*. Synonyms: none. Chromosome number: not known.

Description Very small mouse with soft pelage. Dorsal pelage variable shades of pale buff or pale buffy-orange; hairs slate-grey at base; some have black tip giving a slightly grizzled appearance (though less so than in *M. indutus*). Flanks lack black-tipped hairs and are buffy-orange. Ventral pelage pure white; white colour extends high up on flanks, and dorsally across rump to form white band anterior to tail – a unique character of this species. Head with pointed nose and long vibrissae. Chin, cheeks and muzzle white. Ears comparatively

long (cf. *M. minutoides*) and rounded, pale brown; small white patch at base of each ear. Limbs short with white feet; four digits on forefeet; five digits on hindfeet. All digits with well-developed claws. Tail short (ca. 60% of HB), whitish. Nipples: not known.

Geographic Variation None recorded.

Similar Species

M. minutoides. Dorsal pelage generally darker, tail dark above; white ventral pelage does not extend on to upper rump and muzzle; allopatric.

M. indutus. Ears shorter; white ventral pelage does not extend on to upper rump and muzzle; sympatric.

Distribution Endemic to Africa. Parts of South-West Arid Zone (Kalahari Desert) and Zambezian Woodland BZ. Recorded only from NE Namibia, NW Botswana and W Zambia, with a single record from S Botswana (Vermeiren & Verheyen 1983). Perhaps present in SE Angola. The record from S Botswana suggests a wider geographic range than currently known.

Habitat Poorly known. In Botswana, recorded from the fringes of pans and wetlands in relatively arid habitats (mean annual rainfall 400–450 mm).

Abundance No information. The species is poorly represented in museum collections, suggesting that it is not abundant.

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

The restricted geographic range, apparent rarity and lack of records from protected areas may be cause for concern.

Key References Petter 1978; Vermeiren & Verheyen 1983.**A. Monadjem*****Mus sorella* SORELLA PYGMY MOUSE (THOMAS'S PYGMY MOUSE)**

Fr. Souris naine de Thomas; Ger. Zentralafrikanische Zwergmaus

Mus sorella (Thomas, 1909). Ann. Mag. Nat. Hist., ser. 8, 4: 548. Kirui, Mt Elgon, W Kenya. 6000 ft (1830 m).

Taxonomy Originally described in the genus *Leggada*. Subgenus *Nannomys*. A species within the 'sorella group', characterized by the presence of V-shaped choanae, which also includes the closely related *M. goundae*, *M. neavei* and *M. oubanguii*. Phylogenetic relationships within the 'sorella group' need systematic revision (Musser & Carleton 1993, 2005). Synonyms: *acholi*, *kasaicus*, *wamae*. Subspecies: none. Chromosome number: not known.

Description Very small greyish mouse with pure white ventral pelage. Dorsal pelage dark greyish-brown, with pale-coloured speckles; hairs grey at base, beige or pale brown at tip; some hairs on back longer with black tip. Flanks paler, due to presence of rufous or pale brown hairs and absence of black-tipped hairs. Ventral pelage pure white. Colour of dorsal pelage and ventral pelage very clearly delineated high up on flanks (more so than in other species of *Mus*) without a brownish-orange line of delineation. Head long. Ear comparatively long, dark brown, sparsely covered with short fine hairs. Small white subauricular spot. Upper lips, lower cheeks, chin, throat and chest pure white. Fore- and hindfeet white. Tail short (ca. 65% of HB). Skull: rostrum slender; choanae V-shaped; incisors proodont, anterior palatal foramina long, reaching to the anteriolateral cusp of M¹. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

M. musculoides/minutoides. Similar in total length; HB on average smaller (*M. minutoides*); tail longer (mean 50 mm, ca. 100% of HB); ear on average shorter (mean 8.9 mm); common and widespread.

Distribution Endemic to Africa. Northern and Eastern Rainforest–Savanna Mosaics close to the Rainforest BZ (East Central and West Central Regions). Recorded from NE and SE DR Congo, Uganda, Kenya and N Tanzania (Musser & Carleton 1993). Presence in E Cameroon and EC Angola (Musser & Carleton 2005) uncertain (not mapped). Limits of geographic range unknown.

Habitat Savanna grasslands and woodlands, especially where grasses are tall; grassland areas close to gallery forests along rivers (NE DR Congo; Verheyen 1965b).

*Mus sorella*

Remarks In Garamba N. P., E DR Congo, sympatric with *M. minutoides* (Verheyen 1965b). Seeds and fragments of burnt material were the principal items in stomach contents (Verheyen & Verschuren 1966). Preyed on by owls in Kagera N. P., Rwanda (X. Misonne in Verheyen 1965b).

Conservation IUCN Category: Least Concern.

Mus spretus ALGERIAN MOUSE (WESTERN MEDITERRANEAN MOUSE)

Fr. Souris sauvage; Ger. Algerische Maus

Mus spretus Lataste, 1883. Actes Soc. Linn. de Bordeaux, ser. 7, 4: 27. Oued Magra, between M'sila and Barika, N of Hodna, Algeria.

Taxonomy Subgenus *Mus*. Various considered as a valid species, or as a subspecies of *M. musculus*. Karyology, electrophoresis, DNA hybridization and mitochondrial RNA sequences suggest *M. spretus* is linked with *M. spicilegus* and *M. musculus*, and is a member of the clade that includes *Mus macedonicus*, *M. spicilegus* (both non-African) and *M. musculus* (details in Musser & Carleton 2005). Synonyms: *caocci*, *hispanicus*, *lusitanicus*, *lynsei*, *mogrebinus*, *parvus*, *rifensis*. Subspecies: none. Chromosome number: 2n = 40, FN = 40.

Description Small mouse similar to *Mus musculus*, but smaller and often with shorter tail. Pelage short and dense. Dorsal pelage brownish, slightly flecked with pale brown; hairs dark grey with pale brown or black tip. Ventral pelage greyish-white, clearly delineated from colour of flanks; hairs grey on basal half, white on terminal half. Head similar in colour to dorsal pelage; face rather pointed. Ears darkly pigmented. Limbs short. Fore- and hindfeet with small sparse white hairs. Tail long (ca. 80% of HB), bicoloured, ringed with very small scales; many extremely small bristles. Notch on inner surface of upper incisors not well developed (cf. *M. musculus*); sometimes barely visible. Nipples: not known.

Mus spretus

Geographic Variation None recorded.

Similar Species

M. musculus. Dorsal pelage dark grey; ventral pelage grey; tail on average longer (66–85 mm, 90–100% of HB); notch on inner surface of upper incisors well developed; commensal.

Apodemus sylvaticus. Larger in all dimensions; tail ca. 107% of HB; often syntopic.

Distribution Mediterranean Coastal BZ and coastal regions of Sahara Arid BZ. In Africa, recorded from Morocco, Algeria, Tunisia and Libya. In Algeria, extends from sea level to the northern parts of Haut Plateaux (Kowalski & Rzebik-Kowalska 1991), and in Morocco from coastal regions near Tangiers to limits of cultivation in the sub-Sahara as well as some oases (Aulagnier & Thévenot 1986). Distribution in Libya uncertain; reference to the 'wild form' of *M. musculus* (Ranck 1968) probably refers to *M. spretus*, which is commoner in the interior than near the coast. Extralimital in S France, Spain, Portugal and Balearic Islands. Probably indigenous to the Maghreb and subsequently expanded northwards into southern Europe (Dobson 1998, Dobson & Wright 2000).

Habitat In Algeria, recorded from the seashore to alpine meadows at 1600 m (Kowalski & Rzebik-Kowalska 1991). Tends to prefer habitats with sparse woody vegetation interspersed with open ground, as well as agricultural fields (Khidas *et al.* 2002). In Morocco, lives on plains and hills, as well as cultivated areas, grasslands and forests (Aulagnier & Thévenot 1986). Although largely sympatric with *M. musculus*, it is usually not syntopic and is not commensal (cf. *M. musculus*).

Abundance Varies greatly according to habitat. Commonest species of small mammal in mixed woodlands (dominated by *Phylliria latifolia*, *Pinus halepensis* and *Arenia maritima*) near sea level in Algeria (*M. spretus* 46%, *Gerbillus campestris* 32%, *Apodemus sylvaticus* 12%, *Lemniscomys barbarus* 9%; n = 43). In an oak–olive forest, comprised 80% of two spp. of small mammals (n = 10) (Khidas 1993). Rare or absent in five other sampled habitats from 250 to 1800 m (Khidas 1993). Highest population numbers are often in agricultural fields.

Adaptations Terrestrial. Individuals appear to be less capable of coping with cold conditions than *M. musculus*. Experimentally, in both species, when Ta = 5–35 °C, Tb = 35–37 °C. When Ta is reduced to 0 °C, Tb decreased to ca. 33 °C (whereas for *M. musculus*, Tb remained

normal). At $T_a = 20\text{--}25^\circ\text{C}$, oxygen consumption (as a measure of metabolic rate) was $3\text{--}7\text{ cm}^3/\text{g/h}$ for both species; when $T_a = 0^\circ\text{C}$, metabolic rate remained at $3\text{--}7\text{ cm}^3/\text{g/h}$ in *M. spretus*, but increased to $11\text{--}20\text{ cm}^3/\text{g/h}$ in *M. musculus* (S.D. $\pm 0.63\text{--}\pm 1.07$). Although results are variable (and for *M. musculus* depend on where the individuals originated), *M. spretus* seems less capable of altering metabolic rate (and therefore maintaining Tb) when T_a is low than *M. musculus* (Gorecki *et al.* 1990).

Foraging and Food Mainly fruits and seeds (Aulagnier & Thévenot 1986, Khidas *et al.* 2002).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure In Algeria, ♂♂ with enlarged testes from May–Nov, and lactating ♀♀ from Jun–Nov (Kowalski & Rzebik-Kowalska 1991). Embryo number: 4 ($n = 1$). In S Spain (a climate similar to that of the Mahgreb), reproductive season is from Mar–Nov, with peaks in reproductive activity in Apr–May and Aug–Sep (Antunez *et al.* 1990). Reproductive activity is probably associated with food abundance, and therefore varies from year to year (Duran *et al.* 1987, in Fons & Saint Girons 1993).

Predators, Parasites and Diseases Probably common in owl pellets in Algeria, although difficult to distinguish from *M. musculus* (Kowalski & Rzebik-Kowalska 1991). In Morocco, comprised 65% of small prey in pellets of Barn Owls *Tyto alba* (Aulagnier & Thévenot 1986). Ectoparasites include a flea, *Nosopsyllus barbarus* (Beaucornu & Kowalski 1985).

Conservation IUCN Category: Least Concern.

Mus tenellus DELICATE PYGMY MOUSE

Fr. Souris naine délicate; Ger. Zarte Zwergmaus

Mus tenellus (Thomas, 1903). Proc. Zool. Soc. Lond. 1903: 298. Roseires, Blue Nile, Sudan.

Taxonomy Originally described in the genus *Leggada*. Subgenus *Nannomys*. Morphologically and ecologically similar to *M. haussa*. Setzer

(1956) placed *aequatorius* and *delamensis* (in the Sudan) as subspecies of *bellus* (now a synonym of *M. musculoides*), but Musser & Carleton (1993, 2005) allocated these forms to *M. tenellus*. Synonyms: *aequatorius*, *delamensis*, *gerbillus*, *suahelicus* (Petter 1972b, Musser & Carleton 1993). Subspecies: none. Chromosome number: not known.

Mus tenellus

Description Very small pale-coloured mouse, similar in colour to *M. haussa*. Dorsal pelage pale sandy, sometimes darker on mid-dorsal line. Ventral pelage pure white. Colour of dorsal pelage and ventral pelage clearly delineated on flanks. Chin and throat pure white. Ears short, grey. White sub- and postauricular patches (which may form a white ring around the base of each ear); the only species of *Mus* with such extensive patches. Fore- and hindfeet white. Hindfeet narrow. Tail of moderate length (ca. 70% of HB), scaly, with very small bristles, dark above, pale below. Skull: choanae U-shaped, anterior palatal foramina small, rounded; incisors opisthodont; M^1 56–61% of $M^1\text{--}M^3$, M^3 15–20% of $M^1\text{--}M^3$; M_1 with anterior lobe tricuspidate (cf. *M. haussa*). Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species No other species of *Mus* has such an extensive postauricular patch (or tuft) of white hairs (see Description).

M. haussa. Similar size; no postauricular patch of white hairs; allopatric.
M. minutoides/musculoides. On average larger; dorsal pelage darker (golden-brown flecked with dark brown).

Distribution Endemic to Africa. Guinea Savanna and Somalia–Masai Bushland BZs. Recorded from C Sudan, Ethiopia (below 2000 m), S Somalia (not mapped) and southwards through Kenya to C Tanzania (Musser & Carleton 1993, 2005). Limits of geographic range unknown.

Habitat Grass steppe with thicket clumps.

Abundance Uncertain. Rarely collected. In S Ethiopia comprised <1% of 8 spp. (n = 138) and 2.5% of 6 spp. (n = 38) at two localities (1200–1500 m) (Rupp 1980).

Remarks Embryo number: 3 (n = 1; Nuba Mts, Sudan; Nov), 4 (n = 1; Darfur, Sudan; Sep) (labels; BMNH).

Conservation IUCN Category: Least Concern.

Mus triton GREY-BELLIED PYGMY MOUSE

Fr. Souris naine à ventre gris; Ger. Graubauchzwergmaus

Mus triton (Thomas, 1909). Ann. Mag. Nat. Hist., ser. 8, 4: 548. Kirui, Mt Elgon, Kenya. 6000 ft (1830 m).

Taxonomy Originally described in the genus *Leggada*. Subgenus *Nannomys*. Despite differences in some measurements (e.g. HB and T), over a considerable altitudinal range (1000–3400 m), there generally seems to be a broad morphological uniformity in named forms (e.g. *triton* from Mt Elgon, *fors* from W Rwenzori [both Delany 1975], *birungensis* from west of L. Kivu and *imatongensis* from Imatong Mts in S Sudan [F. Dieterlen unpubl.]); hence subspecific distinctions are of dubious validity. Synonyms: *birungensis*, *fors*, *imatongensis*, *murilla*, *naivashae*. Subspecies: none recognized here. Chromosome

number: 2n = 32, FN = 34 (DR Congo); 2n = 20, 21, 22, FN = 34 ♂♂, 2n = 32 (♀♀) (Tanzania, Malawi) (Matthey 1963b, 1966b, Jotterand-Bellomo 1988).

Description Small mouse, although comparatively large for a pygmy mouse. Dorsal hairs 7–12 mm. Dorsal pelage darkish-brown, slightly flecked with buff or yellow; hairs dark grey at base, with black subterminal band and with black or buff or yellow at tip. Rump generally darker due to more black-tipped hairs. Flanks and head brownish due to more yellowish-tipped hairs. Ventral pelage medium grey to greyish-white, sometimes tinged with yellow; hairs dark grey at base, buff, off-white or white at tip. Ventral and dorsal colours delineated by buff or yellowish stripe (adults only). Ears dark with sparse covering of short brownish hairs. Fore- and hindfeet brownish or yellowish. Tail short (ca. 70% of HB), covered with short bristles, dark above, paler below. Skull stoutly built; mesopterygoid fossa narrow compared to *M. bufo*; anterior palatal foramina extending to the antero-internal root of M². Nipples: 3 + 2 = 10.

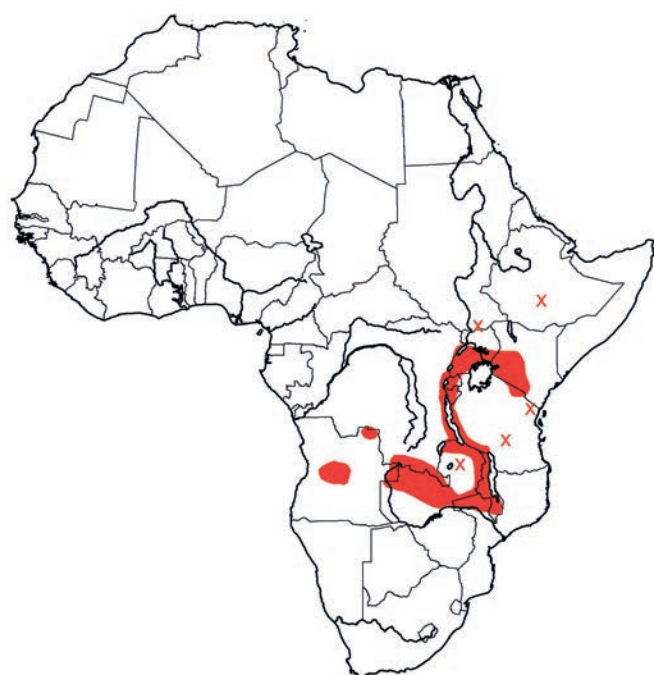

Geographic Variation See Taxonomy.

Similar Species

M. bufo. On average smaller; ventral pelage buff; tail longer and relatively longer; chromosome number: 2n = 36; mountains of Albertine Rift Valley.

M. mahomet. Smaller; ventral pelage greyish-white; tail similar in length; chromosome number: 2n = 36; mainly Ethiopia.

M. minutoides. Much smaller; ventral pelage pure white; tail shorter; chromosome number: 2n = 18–34; widely sympatric.

Mus triton

Distribution Endemic to Africa. Zambezi Woodland BZ and adjacent parts of Eastern and Southern Rainforest–Savanna Mosaics; also Afromontane–Afroalpine BZ in eastern Africa. Recorded from Ethiopia (Bale Mts), S Sudan (Imatong Mts only), NE and N DR Congo, Uganda, Rwanda, Burundi, Kenya, Tanzania, Malawi, Mozambique (Tete district) and Angola (mainly N and NE). In much of eastern Africa, restricted to isolated mountain and highland areas.

Habitat Recorded in many types of grasslands, scrublands, swampy areas and cultivations from 1000 to 3500 m. Typical habitats include grassy areas and slopes (Imatong Mts, Sudan; F. Dieterlen unpubl.), savanna with a dense moist grassy cover (NE DR Congo; Misonne 1963), ‘grass-bush’ and cultivated secondary savanna (west of L. Kivu, E DR Congo; Dieterlen 1967a), *Imperata–Hyparrhenia* grassland (Rwenzori Mountains N. P., Uganda; Delany 1972, 1975), and grasslands in high and moderate rainfall areas (including burnt grasslands) and cultivation (Malawi; Hanney 1965, Happold & Happold 1989a, b). Also recorded in wet montane grasslands at higher altitudes (Kenya, Tanzania; Martin & Dickinson 1985, Stanley *et al.* 1998b). In Bale Mts, Ethiopia, confined to forest habitats (Yalden 1988). On Rwenzori Mts, Uganda, found in low montane forest (1900 m) but not at higher altitudes (cf. *M. bufo*) (Kerbis *et al.* 1998).

On Zomba Plateau, Malawi (1900 m), trapping data showed that *M. triton* preferred montane grasslands (61% of captures) to bracken (26%) and tangles (7.5%), and no individuals were found in adjacent montane forest habitats. They also showed a slight preference for unburnt grasslands (39%) to burnt grasslands (22%), but they moved into burnt grasslands when the burnt grasses sprouted. There was also a clear preference for unburnt bracken (24%) that provided some cover to burnt bracken (2.5%) that provided no cover (Happold & Happold 1989a).

Abundance In montane grasslands on Zomba Plateau in Malawi, *Mus triton* was the most abundant species, forming 37% of all trappable small mammals on a yearly basis (8 spp. rodents, 1 sp. shrew; n = 218 individuals). Population numbers remained more or less constant throughout the year, although population structure changed seasonally – see below (Happold & Happold 1989a). Abundance varies by locality at any one time: in Malawi in Apr–May: 9% on Nyika Plateau (where *Rhabdomys pumilio* and *Lophuromys flavopunctatus* were the commonest species), 20% on Zomba Plateau (where *Lophuromys flavopunctatus*, *Mus triton* and *Praomys delectorum* were the commonest species) and 2% on Mulanje Mt (where *Lophuromys flavopunctatus*, *Rhabdomys pumilio* and *Praomys delectorum* were the commonest species) (Happold & Happold 1989b).

Adaptations Terrestrial and mainly nocturnal. Daily activity (as assessed by trapping) is both nocturnal (ca. 70%) and diurnal (30%) (Rahm 1967). Individuals run on the ground, probably using the runways made by larger rodents. They do not dig burrows, but make nests, which are hidden at the bases of clumps of grass.

Foraging and Food Omnivorous, primarily insectivorous. In Malawi, 81% of stomachs (n = 36) contained insects, mostly adult beetles, and one stomach contained only ant pupae; 28% of stomachs contained white vegetable material (but never green cells) and 8% contained earthworms (Hanney 1965). In DR Congo, five of nine stomachs contained vegetable material (mostly sorghum) and four

contained mainly insects (Dieterlen 1967a). Foraging appears to be opportunistic.

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Reproductive season varies according to locality. In Queen Elizabeth N. P., Uganda, where rain may fall in every month, pregnant ♀♀ recorded during months when rainfall is greater than 50 mm/month (Apr–Jul, Aug–Dec); pregnancy rate varies monthly and in the same month in different years depending on seasonal and yearly changes in rainfall (Delany & Neal 1969, Neal 1986). In a single wet season, each ♀ produces two (sometimes three) litters. In Kivu, E DR Congo, most reproduction is during the wet season (Oct–Mar) when pregnant and/or lactating ♀♀ comprise ca. 40% of all adult ♀♀ with a peak of reproduction of ca. 65% in Jan–Feb. Mean annual reproductive rate of all adult ♀♀ is ca. 30%. No reproduction recorded at end of dry season (Aug–Sep) (Dieterlen 1967a). Further south in Malawi, young recorded during wet season (ca. Dec–Mar) and in the early dry season (Apr–Jul); young not recorded in late dry season (Aug–Nov) (Happold & Happold 1989a). Reproductive rate appears to be comparatively low. Gestation: not known. Embryo number: Uganda: 4.50 (2–6, n = 14; Delany 1975); Kivu: 4.31 (2–7, n = 16; Dieterlen 1967c); Malawi: 6.0 (2–7, n = 5; Hanney 1965). At birth, WT = 0.8 g, HB: 23 mm, T: 9 mm, HF: 4 mm, E: 0 mm and not yet open (n = 5). Day 25–30: WT: = 4–5 g. Day 50: WT: = ca. 8 g. Maturity: WT: = 9–10 g and HB: >70 mm (♀♀) (Dieterlen 1967c.)

In Malawi, during late dry season, most individuals in population are subadults (WT: 9–10 g). By early wet season (Nov), subadults are now adults and some ♀♀ are pregnant (WT: 12–20 g). During the wet season (Dec–Mar), populations composed of juveniles, subadults and adults (range 8–20 g). Mortality of many/most adults between Jun and Sep (dry season, often cool) (Malawi; Happold & Happold 1989a). Proportion of young in population varies seasonally: 0% in late dry season, 15–20% in early wet season, 43–45% in late wet season, and 11% in early dry season by which time young have become subadults and reproduction has ceased. Survival rate in population (data from CMR studies): two months – 0.4; four months – 0.2; six months – 0.1 (Happold & Happold 1989a).

Predators, Parasites and Diseases Occasionally preyed upon by African Grass-owls *Tyto capensis* in Malawi (Happold & Happold 1986); comprised 8–13% of prey in montane grasslands, contributing only 2% of prey biomass. In Malawi, 6.1% (n = 99) of individuals were diseased, mostly by diphyllbothriid larvae (tapeworms; Cestoda). Infection rate was 14–15% in Feb–May and 0% (n = 44) in Oct–Nov. The high infection rate by this parasite in *M. triton* is similar to that in *Lophuromys flavopunctatus* (see Hanney 1964), suggesting similar or identical feeding habits (Hanney 1965). Also parasitized by (adult) *Hymenolepis* sp. (Cestoda) (Hanney 1965).

Conservation IUCN Category: Least Concern.

Fritz Dieterlen & D. C. D. Happold

GENUS *Myiomys*

Mill Rats (Three-toed Grass Rats)

Myiomys Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 224. Type species:
Myiomys cunningghamei Thomas, 1906 (= *Golunda dybowskii* Pousargues, 1893).

Myiomys dybowskii.

Figure 77. Skull and mandible of *Myiomys dybowskii* (RMCA 37016).

The genus *Myiomys* contains two species, one widely distributed in eastern and central Africa, and the other restricted to the type locality in Ethiopia. The preferred habitat is grassland and forest–grassland mosaic (*M. dybowskii*) or forest (*M. rex*).

The genus is characterized by reduction of the number of digits on the forefoot: Digits 1 and 5 are reduced or vestigial, so there are only three functional digits (cf. *Arvicanthis* and *Pelomys* with four digits [Digit 1 absent, Digits 2, 3 and 4 normal, Digit 1 reduced]). Skull with heavy rostrum, strong supraorbital ridges, large interparietal, thick zygoma, low zygomatic plate, and narrow palate. Upper incisors grooved (cf. ungrooved upper incisors in *Arvicanthis*, grooved in *Pelomys*). Molars unusually broad and strong, and cusps very prominent. Upper molar teeth closely crowded together (Ellerman 1941). The cusps of upper molars face backwards whereas the cusps of the lower molars face forwards (Figure 77).

There are some striking external similarities between *Myiomys* and species of *Pelomys* and *Arvicanthis*, but a real relationship exists only with *Pelomys* (Ellerman 1941, Musser & Carleton 2005). Although similarities in the characteristics of the teeth suggest that species of *Myiomys* should be placed with *Pelomys* (Heim de Balsac 1967a, Heim

de Balsac & Bellier 1967), most taxonomists consider *Myiomys* and *Pelomys* to be different genera. Morphological features link *Myiomys* to *Arvicanthis*, *Pelomys*, *Rhabdomys* and *Lemniscomys* (Musser 1987b), as do studies on mitochondrial DNA sequences (mitochondrial DNA cytochrome *b*, 12S and 16S rRNA gene sequences) (Ducroz *et al.* 2001). Molecular results suggest that *Myiomys*, *Pelomys* and *Arvicanthis* form a single lineage (Ducroz *et al.* 2001).

Musser & Carleton (1993) recognized only one species, *M. dybowskii*, with eight synonyms (originally described as species or subspecies). A giant specimen without skull from Ethiopia, described as *Desmomys (Arvicanthis) rex* (Thomas 1906b), was provisionally placed in synonymy (Musser & Carleton 1993), but is listed as a valid species *Myiomys rex* by Musser & Carleton (2005).

The two species are distinguished by size and geographic distribution.

Fritz Dieterlen

Mylomys dybowskii DYBOWSKI'S MILL RAT (DYBOWSKI'S THREE-TOED GRASS RAT, COMMON MYLOMYS)

Fr. Souris de Dybowski; Ger. Mylomys-Grasratte (Dybowskis Mühlenratte)

Mylomys dybowskii (Pousargues, 1893). Bull. Soc. Zool. France 18: 162.

Kemo River, French Congo (= Central African Republic). (06° 17' N, 17° 15' E).

Taxonomy Originally described in the genus *Golunda*. At one time placed in the genus *Pelomys* (e.g. by Ellerman 1941). Following Petter (1962), the form *lowei* from W Africa is maintained as a valid and separate species, *M. lowei*, by Rosevear (1969) and Grubb *et al.* (1998), but is considered here as a synonym of *M. dybowskii* (see Musser & Carleton 2005). The form *richardi* from lower DR Congo appears to be a special taxon and could be a distinct species (F. Dieterlen unpubl.). Synonyms: *alberti*, *christyi*, *cuninghamei*, *lowei*, *lutescens*, *massaicus*, *richardi*, *roosevelti*. Subspecies: none currently recognized. Chromosome number: $2n = 42$ from Central African Republic (Matthey 1970) and Guinea (Gautun *et al.* 1986). Autosomes comprise 8 large and 32 very small chromosomes – an unusual situation among murid rodents (Matthey 1970).

Description Large stoutly built and impressively coloured rat with a strong and rather thick tail as in most arvicanthine rats. Pelage glossy, dense, coarse and long (ca. 15 mm on back). Dorsal pelage pale brown, heavily streaked with black; hairs dark grey or black, with yellow or blackish tip. Scattered black guard hairs (up to ca. 19 mm), especially on back. Tips of hairs on rump and at base of tail russet. No mid-dorsal black stripe (cf. some *Pelomys* spp.). Ventral pelage off-white, shorter than dorsal pelage; hairs off-white. Colour of dorsal and ventral pelage clearly delineated. Head uniformly similar in colour to dorsal pelage. Lower cheeks, chin and chest off-white. Small patches of yellowish or orange hairs on nose, around the eyes and at the front base of ears in some individuals. Ears large and rounded at tip; pigmented and sparsely

covered with short pale brown and black bristles. Hairs on cheek may obscure base of ear. Fore- and hindfeet similar in colour to dorsal pelage. Forefeet small, with three functional toes (Digits 2, 3 and 4); Digit 1 and 5 small or vestigial; well-developed palmar pads. Hindfeet long and strong with five digits, Digits 2, 3 and 4 long (up to 7 mm) with long curved claws (3 mm); Digits 1 and 5 shorter, reaching to bases of Digits 2, 3 and 4. Tail long (ca. 92% of HB), ringed with small scales, bicoloured, dark and pigmented with short blackish bristles above, paler with whitish or yellowish bristles below. Skull: well-developed supraoccipital ridges; upper incisors each with a single groove towards the outer side of the tooth; orthodont. Cheekteeth extremely cuspidate in young animals. Each upper molar tooth angled posteriorly at 40–45° to supporting maxilla bone (more so than in other murids); each lower molar tooth angled anteriorly at ca. 40–45° to supporting mandibular bone. Nipples: 2 + 2 = 8.

Geographic Variation The western forms (*dybowskii*, *richardi* and *lowei*) from Guinea to the Central African Republic are slightly larger than those from eastern Africa.

Similar Species

Pelomys fallax. Ventral pelage similar in colour to dorsal pelage; mid-dorsal stripe (sometimes indistinct); each upper incisor with groove. *Arvicanthis* spp. Ventral pelage similar in colour to dorsal pelage; each upper incisor without groove.

Distribution Endemic to Africa. Northern and Eastern Rainforest–Savanna Mosaics; outlier populations in Zambezi Woodland and Somalia–Masai Bushland BZs and in parts of the Afromontane–Afroalpine BZ of eastern Africa. Distribution widespread but disjunct. Recorded from C and W Kenya, Uganda, W Tanzania (Mahali Mts), Malawi (Nyika Plateau), NE Rwanda, S Sudan (S Equatoria Province on both sides of Nile R.), DR Congo (non-forested areas west of L. Kivu and L. Edward, and on both sides of Lower Congo R. from near Kinshasa to the Atlantic coast); Congo (north of Lower Congo R. from near Brazzaville to the Atlantic coast), Central African Republic (north of Ubangi R. from ca. 04° N to ca. 06–07° N), and parts of E, C and W Cameroon: Outlier populations in W Ghana (Wenchi only, as *M. lowei*; Grubb *et al.* 1998), Côte d'Ivoire and Guinea (Mt Nimba). No records from Nigeria, Benin and Togo.

Habitat *Mylomys dybowskii* is – apart from a few exceptions – an inhabitant of the Rainforest–Savanna Mosaics. Preferred habitats are moist and tall grasslands with scattered trees and/or shrubs. Recorded from *Imperata cylindrica*, *Cymbopogon afronardus* and *Themeda triandra* grasslands (Queen Elizabeth N. P., Uganda; Neal 1970, Cheeseman & Delany 1979); forest–grassland mosaic (Didinga Mts, SE Sudan; H. Rupp unpubl.); montane grasslands up to 2300 m (NE

*Mylomys dybowskii*

and E DR Congo [Misonne 1963, Rahm 1967]; Malawi [Chitaukali *et al.* 2001]), and grasslands and clear-cut areas at the edge of rainforest (Côte d'Ivoire; Bellier 1967).

Abundance In most habitats, *M. dybowskii* is recorded as rare. In a few localities may be locally quite common: e.g. in one locality in Queen Elizabeth N. P., Uganda, it comprised 44% of all rodents (9 spp.; n = 140), yet was absent at five other savanna localities in the N. P. (Delany 1964b). In another study in Queen Elizabeth N. P., it comprised 7–21% (mean 13%) of all small rodents (6 spp.), and 12–35% (mean 22%) of total biomass during the eight months before the grasslands were burned (Cheeseman & Delany 1979). The proportion of *M. dybowskii* fell to 1–5% of all rodents during three of the nine months after burning, and to 0% during the other six months, including those 8–9 months after the fire when new grasses had sprouted. In this respect, *M. dybowskii* is similar to sympatric *Lophuromys sikapusi*, and it is much less 'fire-adapted' compared with other sympatric species (e.g. *Lemniscomys striatus*, *Mus triton*, *Mastomys natalensis*). In unburnt grasslands in Côte d'Ivoire, comprised 16%, and was the third most numerous species of small mammals after *Dasyms incomtus* and *Uranomys ruddi* (n = 177; 8 spp.) (Bellier 1967).

Adaptations Terrestrial and mostly diurnal. Probably fast-running, and perhaps leaping, as suggested by the rather short forefeet and the long hindfeet, which bear three long central toes with long claws. Verheyen & Verschuren (1966) report that they do not use burrows and their grass nests are normally on the ground. The alimentary canal has a very large caecum and colon (comprising ca. 60% of the total length), indicative of a mainly grass diet (Dieterlen 1967b).

Foraging and Food Herbivorous. Contents of 25 stomachs from W Uganda contained only grass leaves and stems (Delany 1964b). Two specimens from cultivated land in Kivu, DR Congo, had very large stomachs containing a homogeneous green pulp, mostly of green beans, grass and herbs (Dieterlen 1967b).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure In Queen Elizabeth N. P., Uganda, reproduction occurs in most months of the year; pregnancies recorded in all months except Jan and Feb (no samples), Jul and Aug. For months when pregnancies were recorded, 50–100% of ♀♀ were pregnant except for Sep (n = 1–8 ♀♀/month; Delany & Neal 1969). Very young animals found in all months except Mar, Apr, Sep and Nov (Delany 1975). Embryo number: mean 4.32 (2–6, mode 5, n = 28 litters; Delany 1975). Dorsal pelage in young animals is dull blackish-brown, usually without yellowish tinge, and ventral pelage is greyish; subadults have a slight warm glossy yellowish tinge (and may be confused with young *Pelomys fallax*).

Predators, Parasites and Diseases Remains found in stomach of a Puff Adder *Bitis arietans* in Uganda (Cheeseman & Delany 1979). *Mylomys dybowskii* belongs to the small mammalian fauna of the endemic plague regions in NE and E DR Congo (Fain 1953, Misonne 1959). In Central African Republic, forms of *Toxoplasma* found in parasitizing Thrombiculids mites (Giroud *et al.* 1952).

Conservation IUCN Category: Least Concern.

Mylomys rex KING MILL RAT (ETHIOPIAN THREE-TOED GRASS RAT, ETHIOPIAN MYLOMYS)

Fr. Souris d'Ethiopie; Ger. Königsmühlenratte

Mylomys rex (Thomas, 1906). Ann. Mag. Nat. Hist., ser. 7, 18: 304. Charada Forest, Ethiopia.

Taxonomy Originally described in the genus *Arvicanthis*. This species is known only from the holotype. When describing this species, Thomas (1906b) remarked that it was likely to be a large form of *Desmomyss*, a genus sometimes considered as a synonym or subgenus of *Pelomys*. Hence, *rex* has been referred to as *Pelomys rex* for the past 90 years (e.g. by Yalden *et al.* 1976; Yalden & Largen 1992). The species is known only from the holotype. However, Musser & Carleton (1993) correctly point out that *rex* is in fact a *Mylomys*; they doubted its separation from central and West African *M. dybowskii* and considered *rex* as a synonym. Later (in 2005) these authors reinstated *rex* as a valid species on the basis that it is larger than *M. dybowskii* and lives in tropical deciduous forest. Musser & Carleton (1993, 2005) questioned the locality of the holotype, but there is no doubt that it

was collected by Peter Zaphiro in Ethiopia: his distinctive hand-writing is evident on the original collection label, and the locality and date of collection are consistent with his published route map. There is a large gap in geographic range between the type locality in Ethiopia and the nearest localities of *M. dybowskii*. Without more specimens and a full taxonomic appraisal, it seems premature to sink this species into synonymy. Synonyms: none. Chromosome number: not known.

Description Very large, harsh-furred rat, looking like a large *Arvicanthis*. Dorsal pelage speckled sandy-brown, redder around the rump. Ventral pelage bluish-white, with a sharp delineation between dorsal and ventral colours. Tail long (ca. 83% of HB), coarsely ringed. Forefeet with only three functional toes.

Geographic Variation None recorded.

Similar Species

M. dybowski. Similar in form, but smaller in external dimensions; widespread but not recorded in Ethiopia.

Pelomys fallax. Ventral pelage similar in colour to dorsal pelage; each upper incisor with groove.

Arvicanthis spp. Ventral pelage similar in colour to dorsal pelage; each upper incisor without groove.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Only known from the holotype collected in Charada Forest, Kaffa, Ethiopia (ca. 07° 25' N, 36° 45' E; 1800 m).

Habitat Moist evergreen montane forest.

Abundance Only known from the holotype.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

GENUS *Myomyscus*

Meadow Mice

Myomyscus Shortridge, 1942. Ann. S. Afr. Mus. 36: 93. Type species: *Mus verroxii* (= *verreauxii*) A. Smith, 1834.

Myomyscus brockmani.

The genus *Myomyscus* contains three species, each widely separated geographically from each other. All species live in grassland or heathland habitats, and some may be associated with rocky habitats. The genus is characterized by small body size, long or very long tail (100–140% of HB), brown or grey dorsal pelage, white or whitish ventral pelage, and four or five pairs of nipples. The skull is similar to that of the genera *Mastomys* and *Praomys* (Figure 78).

Two of the species currently assigned to *Myomyscus* were formerly placed in *Myomys*. The genus *Myomyscus* was proposed because, according to some authorities, *Myomys* was an invalid name (Musser & Carleton 1993). However, *Myomys* was still accepted as valid by Musser & Carleton (1993), but current opinion replaces *Myomys* by *Myomyscus*. As a consequence, the six species previously allocated to *Myomys* are reallocated to different genera as follows: *Myomys albipes* (now *Stenocephalemys albipes*), *Myomys daltoni* (now *Praomys daltoni*), *Myomys derooi* (now *Praomys derooi*), *Myomys fumatus* (now *Myomyscus brockmani*), *Myomys ruppi* (now *Stenocephalemys ruppi*) and *Myomys verreauxii* (now *Myomyscus verreauxii*). Thus only two of the original *Myomys* remain within *Myomyscus*, two have been transferred to *Stenocephalemys* (a purely Ethiopian genus) and two have been transferred to *Praomys*. The third species within the genus *Myomyscus* is *M. angolensis* (formerly *Mastomys angolensis*), transferred primarily because it has only five pairs of nipples and is not a 'multimammate rat' with up to 12 pairs of nipples.

The genus *Myomyscus* appears to be polyphyletic (Musser & Carleton 2005). The relationships of the genus are uncertain and contradictory.

Figure 78. Skull and mandible of *Myomyscus brockmani* (HC 266).

Analysis of complete mitochondrial DNA cytochrome *b* sequences places *M. verreauxii* as a sister-group to *Colomys* and *Zelotomys*, and *M. brockmani* as a sister-group to *Mastomys* and *Stenocephalemys*. Chromosomal and immunological studies relate *Myomyscus brockmani* (as *Myomys fumatus*) to species of *Mastomys* (Qumsiyeh *et al.* 1990), and morphometric analysis places *M. verreauxii* closer to *Mastomys* than to other species of *Myomyscus* (Van der Straeten & Dieterlen 1983, Van der Straeten & Robbins 1997). Molecular analysis clusters *Myomyscus* with *Praomys*, *Mastomys*, *Hylomyscus*, *Heimyscus* and *Stenocephalemys* (Fadda *et al.* 2001). These relationships are fully discussed by Musser & Carleton (2005).

The species are distinguished by body size and colouration, tail length, skull characters and geographic distribution.

D. C. D. Happold

Myomyscus angolensis ANGOLAN MEADOW MOUSE (ANGOLAN MYOMYSCUS)

Fr. Souris d'Angola; Ger. Angolische Wiesenmaus

Myomyscus angolensis (Bocage, 1890). Journ. Sci. Math., Phys. Nat., Lisboa, ser. 2, 12.
Capangombe, interior of Moçâmedes District, Angola (15°06' S, 13°09' E). 527 m.

Taxonomy Originally described in the genus *Mus*. This species was known previously as *Mastomys angolensis* but lacks the typical large number of nipples, arranged almost contiguously in two rows, that is so characteristic of multimammate mice. Now assigned to *Myomyscus* (= *Myomys*) (e.g. Hill & Carter 1941, Robbins & Van der Straeten 1989, Crawford-Cabral 1998), an arrangement confirmed by molecular data (Lecompte 2003). Crawford-Cabral (1988) argued that all specimens previously identified as *M. angolensis* were so different from the description of the holotype (now no longer extant), and also in their ecological distribution, that he grouped them in a new species *angolae* in the genus *Mastomys*. Musser & Carleton (1993) considered this to be no more than a renaming of *angolensis*. Synonyms: *angolae*. Subspecies: none. Chromosome number: not known.

Description Medium-sized grey mouse. Dorsal pelage brown to reddish-brown. Ventral pelage grey; hairs dark at base, with white tip. Fore- and hindfeet white. Tail long (ca. 100% of HB); dark reddish-brown above, pale grey below. Skull with considerably wider interpterygoid region than in *Mastomys* species, with which it sometimes is confused. Nipples: 3 + 2 = 10.

Geographic Variation None recorded.

Myomyscus angolensis

Similar Species

Mastomys natalensis. Smaller mean HB and T; tail similar as % of HB; ventral pelage similarly dark grey; much larger geographic distribution; nipples $12 \times 2 = 24$; $2n = 32$.

Mastomys shortridgei. Similar mean HB; mean T shorter and as % of HB; ventral pelage grey with white tips; nipples $5 \times 2 = 10$.

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded from Angola; may also be present in S DR Congo. Sympatric or altitudinally parapatric with *M. natalensis*.

Habitat Humid grasslands in mountain and highland areas above 1000 m. Tolerates more adverse climatic and soil conditions than *M. natalensis*.

Abundance Not common (Hill & Carter 1941).

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Measurements

Myomyscus brockmani BROCKMAN'S MEADOW MOUSE (SMOKY MEADOW MOUSE, BROCKMAN'S MYOMYSCUS)

Fr. Souris fuligineuse; Ger. Rauchgraue Wiesenmause

Myomyscus brockmani (Thomas, 1908). Ann. Mag. Nat. Hist., ser. 7, 18: 298. Upper Sheikh, Somalia.

Taxonomy Originally described in the genus *Mus*. Previously referred to as *Myomys fumatus* (Peters, 1878) by, e.g. Musser & Carleton (1993) and earlier authors. However, Musser & Carleton (2005), following Van der Straeten & Robbins (1997), showed that the holotype of *fumatus* is a species of *Mastomys* and therefore that the oldest available name for this species is *brockmani*. Placed in genus *Praomys*, subgenus *Myomyscus* (together with *M. albipes* [now *Stenocephalemys albipes*], *M. verreauxii* [now *Myomyscus verreauxii*] and *M.*

daltoni [now *Praomys daltoni*] by some authors, e.g. Kingdon, 1974, Misonne 1974, Delany 1975, Nader *et al.* 1983). Synonyms: *allisoni*, *niveiventris*, *oweni*, *subfuscus*, *ulae*. Subspecies: none. Chromosome number: $2n = 38$, $FN = 48$ (Qumsiyeh *et al.* 1990).

Description Small pale brown mouse, with pure white ventral pelage and long tail. Dorsal pelage soft medium brown, especially in mid-line, becoming paler (smoky) on flanks; dorsal hairs dark grey at base with brown tip on mid-line, pale brown or ochre on flanks. Ventral pelage pure white, clearly delineated from colour of flanks. Head similar to dorsal pelage, with white on chin and throat. Ears fairly large, darkly pigmented with scattered short pale hairs. Limbs short, upper surface similar in colour to flanks, undersurface white. Forefoot with four digits; Digit 1 absent. Hindfoot with five digits; Digit 1 small, ending level with base of Digit 5. Tail long (ca. 140% of HB), scaly with scattered short bristles, medium brown above, paler below. Nipples $2 + 2 = 8$, $3 + 2 = 10$ (labels, BMNH).

Geographic Variation None recorded.

Similar Species

Mastomys natalensis. Ventral pelage grey; nipples 16–24 in two equal rows.

Distribution Endemic to Africa. Mainly southern Somalia–Masai Bushland BZ at higher altitudes. Recorded in SE Ethiopia, S Sudan, NW Somalia, N Uganda, Kenya and N Tanzania. Isolated populations on Jebel Marra (W Sudan) and the Central African Republic (Nader *et al.* 1983).

Myomyscus brockmani

Habitat Smoky Meadow Mice live amongst rocks and boulders, usually at altitudes of 3000–6000 ft (1000–3000 m), where rainfall is low and there is a sparse cover of trees and grasses. They have also been found in caves, and amongst volcanic lava (Mt Suswa, Kenya) and in dry *Acacia* savanna (Uganda). Their preference for rocks suggests an alternative common name ‘rock rat’ (Misonne & Verschuren 1966). On Jebel Marra they were found only in dense grassy vegetation beside a stream (Happold 1966b). Sometimes found in local buildings in NE Somalia (labels, BMNH).

Abundance Populations dispersed and often isolated. Generally uncommon, although may be locally abundant. At one locality beside a stream on Jebel Marra, meadow mice formed 90% of the small mammals ($n = 42$).

Adaptations Terrestrial, nocturnal. Domiciles under and amongst rocks and boulders, and in crevices in volcanic lava; presumably does not dig burrows.

Foraging and Food Misonne & Verschuren (1966) record that stomach contents contain ‘matières amylacées’. The rather narrow cheekteeth suggest that these mice eat soft foods.

Social and Reproductive Behaviour Very little information. The density of individuals on Jebel Marra suggest that meadow mice are sociable and non-aggressive.

Reproduction and Population Structure On Jebel Marra in Dec (dry season), 60% of collected animals were juveniles, suggesting that births occurred in the late wet season (Jul–Sep). Embryo number: 6 ($n = 1$; Mt Suswa, Kenya; Aug; BMNH); 7 ($n = 1$; Ethiopia; Jan; BMNH).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Myomyscus verreauxii VERREAUX’S MEADOW MOUSE (WHITE-FOOTED MOUSE)

Fr. Souris de Verreaux; Ger. Verreauxs Wiesenmaus

Myomyscus verreauxii (Smith, 1834). S. Afr. Quart. J., ser. 2, 2: 156. Cape of Good Hope near Cape Town, South Africa.

Taxonomy Originally described in the genus *Mus*. Allocated to the genus *Praomys* (subgenus *Myomyscus*) by De Graaff (1981), Smithers (1983) and Corbet & Hill (1986). Placed in the genus *Myomys* by Musser & Carleton (1993) but now, with the elevation of *Myomyscus* to a valid genus, allocated to the genus *Myomyscus* (Musser & Carleton 2005). The original species name, *verroxii*, was amended to *verreauxi* by Sclater (1901) to agree with the correct name of P. J. Verreaux (taxonomist and curator of the South African Museum in the 1830s) after whom this mouse was named (De Graaff 1997). Relationship uncertain: analyses of mitochondrial DNA cytochrome *b* sequences separate *M. verreauxii* from *M. brockmani* (formerly *Myomys fumatus*) and *M. yemeni* and suggest it may be related more closely to *Colomys* and *Zelotomys* than to other species currently in the genus *Myomyscus* (Lecompte *et al.* 2002b). Musser & Carleton (2005) suggest that ultimately *M. verreauxii* may prove to be the only species of *Myomyscus*. Synonyms: *verreauxi* (only one ‘i’), *verroxii*. Subspecies: none. Chromosome number: not known.

Description Small brown mouse, similar in general appearance to *Mastomys* spp. Pelage long (8–12 mm) and soft. Dorsal pelage buffy-brown; hairs dark grey at base, buffy-brown at tip. Longer thicker black guard hairs scattered throughout most of dorsal pelage, especially on lower back and rump. Flanks similar, paler, with fewer guard hairs. Ventral pelage shorter than dorsal pelage, whitish-grey;

Myomyscus verreauxii

hairs dark grey at base, white at tip. Head similar to dorsal pelage; lip, chin and throat pale buffy-brown. Long black vibrissae. Ears large, naked. Fore- and hindlimbs and feet white. Tail very long (ca. 135% of HB), scaly with very small bristles; darker above, paler below. Juveniles paler than adults. Skull: similar to *Praomys*, but broader; supraorbital ridges absent; anterior palatal foramina end near anterior edge of M¹; mid-point of zygomatic arch tends to bow inwards towards cranium (De Graaff 1981). Nipples: 3 + 2 = 10.

Geographic Variation None recorded.

Similar Species

Mastomys spp. Usually larger; more than ten nipples.

Distribution Endemic to Africa. South-West Cape BZ. Known only from SW Cape Province, South Africa, from Olifants R. in the west to near Plettenberg Bay and Knysna in the east.

Habitat Meadow banks near the coast, and near fallen trees and in grassy vleis in forests. Grasslands with *Protea* spp. may be favoured habitat (De Graaff 1981). In the Cederberg region, north of Cape Town, found mostly in forested valleys (Rautenbach & Nel 1980).

Abundance Little information, although may be locally abundant, e.g. 50% of small mammals (n = 28) trapped in forested valleys in the Cederberg area (Rautenbach & Nel 1980).

Remarks Nocturnal and terrestrial. Two stomachs contained 95% insects and 5% white plant material (Rautenbach & Nel 1980). Feeds

on *Protea* seeds and insects (De Graaff 1981). Three species of fleas (*Dinopsyllus abaris*, *D. ellobius*, *Epirimia aganippes*) and two species of ticks (*Ixodes* sp., *Haemaphysalis leachii*), as well as endoparasitic worms, have been recorded (details in De Graaff 1981).

Conservation IUCN Category: Least Concern.

Listed in the South African Red Data Book of 1976–77; now excluded because quite common in suitable habitats, even though populations are dispersed.

GENUS *Nesokia*

Bandicoot Rats

Nesokia Gray, 1842. Ann. Mag. Nat. Hist., ser. 1, 10: 264. Type species: *Arvicola indica* Gray, 1830.

A genus of large robust rats comprising one or two species. The most widespread species, *Nesokia indica*, is distributed mainly in the Middle East and Asia extending as far west as the extreme NE of Africa. The characteristics of the genus are given in the species account below.

D. C. D. Happold

Nesokia indica SHORT-TAILED BANDICOOT RAT (EGYPTIAN PEST RAT)

Fr. Rat à queue courte; Ger. Kurzschwanz-Bandicootratten

Nesokia indica (Gray and Hardwicke, 1830). Illustr. Indian Zool. 1: pl 11. India (locality uncertain).

Taxonomy Originally described in the genus *Arvicola*. Recorded as *Nesokia bacheri* in Anderson & Winton (1902) and described as a separate species *Nesokia suilla* by Thomas (1907b); *suilla* is now considered to be a junior synonym of the widespread *N. indica*. Considerable morphological variation throughout the worldwide geographic range (see below) suggests that there may be more than one species (Musser & Carleton 1993). External, cranial and dental morphology indicates close relationship with the genus *Bandicota*,

the bandicoot rats of Asia. Bandicoot rats are not related in any way to the marsupial Bandicoots of Australia and New Guinea (Marsupialia: Paramelidae). Synonyms: *suilla* (plus 16 non-African synonyms – see Musser & Carleton 1993, 2005 for details). Subspecies: none. Chromosome number in 90% of population: 2n = 42; polymorphism of sex chromosomes results in 2n = 39, 40 or 41 in 10% of population (Indian specimens; Rao *et al.* 1983).

Figure 79. Skull and mandible of *Nesokia indica* (BMNH 4.8.4.3).

Description Large solidly built rat with dense pelage of relatively coarse hair and short tail. Dorsal pelage medium brown; hairs greyish-brown at base, buff-brown or black on terminal third or half. Scattered long black guard hairs (20–30 mm) project beyond surface of dorsal pelage. Flanks paler. Ventral pelage greyish-brown, sometimes with irregular white patches on chest. Head robust, similar in colour to dorsal pelage. Muzzle blunt. Eyes relatively large. Ears small, slightly pointed at tip, mostly naked, with short black vibrissae. Fore- and hindfeet broad, greyish-brown. Forelimbs with four digits; hindlimbs, five digits. Tail short (ca. 66% of HB), thick, scaly, sparsely covered with short dark bristles. Pelage colouration variable. Skull thickset and robust. Upper incisor teeth broad and slightly pro-odont. Incisors without grooves. Cheekteeth laminate, without cusps in adults. Supraorbital and supraoccipital ridges well developed. Auditory bullae well developed (Figure 79). Nipples: 8.

Geographic Variation None in Egypt other than variation in the size of white patch on chest. Osborn & Helmy (1980) refer to the Egyptian Bandicoot Rat as *N. i. suilla* on account of its smaller size compared with other subspecies.

Similar Species

Rattus norvegicus. Slightly larger with long tail (ca. 90% of HB); hindfoot 40–51 mm; dorsal pelage shaggy brownish-black; ventral pelage grey without white markings.

Nesokia indica

Rattus rattus. On average smaller but with long tail (ca. 120% of HB); hindfoot 25–34 mm; dorsal pelage blackish; ventral pelage pale to dark brown, or lemon-yellow, or white.

Distribution Sahara Arid BZ. In Africa, known only from the western margins of the Nile Delta, El Faiyum, Wadi Natron, Bahariya oasis and near Suez in Egypt. Extraliminally recorded from Saudi Arabia, Israel, Iran, Iraq and eastwards to Pakistan and northern India; and north-eastwards to Turkmenistan and NW China. Distribution in Egypt was more widespread during the wetter periods of the Pliocene, Oligocene and Miocene. Such wet periods probably allowed the species to reach Wadi Natron and the Faiyum (now surrounded by desert) from the Nile valley. Fossil remains of *Nesokia indica* have been found at late Pleistocene sites near Aswan and Wadi Halfa in Nubia on the Sudan border (Osborn & Helmy 1980).

Habitat Although within the Sahara Arid BZ, known only from cultivated areas, gardens, canal banks, borders of saline lakes and palm groves, especially where soil is damp (Osborn & Helmy 1980).

Abundance Populations are scattered and local. May be common in suitable habitats. When numerous, regarded as a pest by local farmers.

Adaptations Nocturnal. Burrows are usually less than 0.5 m below the surface, and vary from 2.5 to 9 m in length (Osborn & Helmy 1980). They are mostly situated in damp soils (e.g. on canal banks). Spill heaps of excavated soil often indicate the position of burrows. A nest may be situated 0.6–1.0 m below the surface (Hoogstraal 1963), apparently deeper than most of the burrow. These rats are regarded as very aggressive, and will bite without hesitation when handled.

Foraging and Food In Egypt, fleshy roots of *Alhagi mannifera* and *Typha elaphantina* were found in storage chambers in burrows. Also feeds on crops of maize, barley and vegetables (Hoogstraal 1963).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Embryo number: 4.7 (1–8). Gestation: 26–28 days. Females nurse young for 30 days after parturition (Iraq; Harrison & Bates 1991). In Egypt, reproductive activity recorded from Feb to Oct; extent and possible seasonality of reproduction in Egypt unknown.

Predators, Parasites and Diseases Fleas have not been recorded from this species, probably because the dampness of the burrows is unsuitable for fleas (Hoogstraal & Traub 1965b). In Iraq, jungle cats, snakes and owls are the main predators (Al-Jumaily *et al.* in Harrison & Bates 1991).

Conservation IUCN Category: Least Concern.

GENUS *Nilopegamys* Ethiopian Water Rat

Nilopegamys Osgood, 1928. Field Mus. Nat. Hist., Zool. Ser., 12: 185. Type species: *Nilopegamys plumbeus* Osgood, 1928.

A monotypic genus occurring only in the highlands of Ethiopia. The genus was described to accommodate the single species *N. plumbeus*, which exhibits many characters associated with a semi-aquatic life-style, and which is far-removed geographically from similar species of the Rainforest BZ. The genus was accepted by Allen (1939) and Ellerman (1941), but subsequently included in *Colomys* by Hayman

(1966), Dieterlen (1983) and Musser & Carleton (1993). Reinstated as a valid genus after the detailed study by Kerbis Peterhans & Patterson (1995) (see also Musser & Carleton 2005). Further details are given in the species profile.

Nilopegamys plumbeus Osgood, 1928. Field Mus. Nat. Hist., Zool. Ser. 12: 185.

Between Sakalla and Njabarra (= Enjibara, Injibarra), Gojam, Ethiopia. 8500 ft (2800 m).

Taxonomy Hayman (1966) placed *N. plumbeus* as a subspecies of *Colomys goslingi*, an arrangement followed by most subsequent authorities (e.g. Misonne 1974; Yalden *et al.* 1976, Dieterlen 1983, Musser & Carleton 1993). Following Kerbis Peterhans & Patterson (1995), *N. plumbeus* is now considered to be a valid species. Known only by the holotype (♂) collected in 1927. Synonyms: none. Chromosome number: not known.

Description Medium-sized semi-aquatic black and white rodent with very long tail and long broad hindfeet. Pelage very soft and dense, suffused with long guard hairs. Dorsal pelage greyish-black; hairs grey at base, blackish at tip. Ventral pelage pure white. Dorsal and ventral colours very clearly delineated. Head rather elongated; muzzle bulbous with vertical cleft on rhinarium and upper lip, and long vibrissae. Eyes small, set high on side of head. Ears small, projecting above pelage, dark, with white fringing hairs on posterior and ventral margins. White postauricular spot. Side of face, upper lips, chin, throat and chest pure white. Shoulder and upper thighs greyish-black as dorsal pelage. Forelimb, greyish-black above, white

below; forefeet pure white. Hindlimbs white; hindfeet white, long and broad, with five digits; Digit 1 with large claw, Digit 5 elongated; soles edged with fringing hairs. Tail very long (ca. 120% of HB), rather broad at base and not laterally flattened, ringed with scales, black above, white below with sharp thin median mid-ventral black line; tip of tail totally black. Skull with flattened dorsal profile (when viewed from side), rostrum straight without ridges, and enlarged foramen magnum (Figure of skull not available). Nipples: not known.

Geographic Variation None recorded.

Similar Species

Colomys goslingi. Similar in colour and pattern; smaller HB, T and WT; HF similar in length but less broad; longer ears; Cameroon to Uganda, Kenya and S Sudan.

Deomys ferrugineus. Dorsal pelage bright rusty-red; ventral pelage white; long naked ears; hindfeet long and slim; S Cameroon and Gabon to Rwanda and Uganda.

*Nilopegamys plumbeus*

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from the type locality in the highlands of Ethiopia, about 70 km south of L. Tana.

Habitat The holotype was taken ‘in a small clear stream, probably nameless but tributary to the Little Abbai not far from its source ... in a little runway leading from the water across a tiny islet’ (Osgood 1928).

Abundance Extremely rare; not seen since 1927.

Adaptations External characters suggest it is semi-aquatic: these include the bulbous muzzle and long vibrissae, the flattened form of the head and high-set eyes, the dense woolly pelage, the stark contrast between dark dorsal pelage and white ventral pelage, and the long

broad hindfeet. It shares some of these characters with *Colomys goslingi* and *Deomys ferrugineus* (and *Malacomys* spp. to a lesser extent), which are also semi-aquatic, although these species are more inclined to be ‘waders’ rather than ‘swimmers’. The flattened profile of the upper surface of the skull and the large foramen magnum are similar to those in other African and non-African semi-aquatic rodents. The brain is enlarged (about 1.5 times larger than expected for a murid rodent of this size), which may indicate that *N. plumbeus* lives in a complex three-dimensional environment (such as rivers and streams) (Kerbis Peterhans & Patterson 1995). The broad hindfoot suggests an ability to swim; however, *N. plumbeus* does not show the adaptations for aquatic life (webs between digits, thick laterally flattened tail) as seen in the otter-shrews (Afrosoricida: Tenrecidae).

Remarks The stomach contents of the holotype had a ‘strong fishy smell’, which may suggest that fish (and perhaps other animal foods) are eaten. The foraging behaviour of *Colomys goslingi* (see Dieterlen & Statzner 1981) may be applicable to *N. plumbeus*.

Conservation IUCN Category: Critically Endangered.

GENUS *Oenomys* Rufous-nosed Rats

Oenomys Thomas, 1904. Ann. Mag. Nat. Hist., ser. 7, 13: 416. Type species: *Mus hypoxanthus* Pucheran, 1855.

The genus *Oenomys* contains two species, *O. ornatus* and *O. hypoxanthus*, which live parapatrically in the Rainforest BZ and in isolated rainforest relics in restricted areas of western and eastern Africa. Although a ‘rainforest’ genus, typical habitats are grasslands, tangles and secondary growth, not rainforest itself.

The genus is characterized by greyish-brown dorsal pelage, with bright russet patches on rump and thighs, bright russet on nose and cheeks, whitish ventral pelage, a medium-sized and relatively long tail, forefoot with four digits and hindfoot with five digits, Digits 1 and 5 considerably shorter than Digits 2, 3 and 4. Principal characters of the long narrow and strongly built skull are: narrow interorbital width with well-developed supraorbital ridges; wide anterior palatal

foramina; supraoccipital ridges with well-developed keels laterally; opisthodont incisors without grooves; cuspidate molars, angled posteriorly; M¹ without t9; and the large central cusps of M¹, M² and M³ form a prominent straight row along length of molars (Figure 80).

The two species of the genus are terrestrial, but capable of climbing in tangles and low branches. Individuals are often active during daylight as well as at night. Nests of grass are built on the ground and up to about 3 m above ground (Dieterlen 1967b, Rosevear 1969). Although uncommon in many areas, population numbers may be very high in preferred habitats (Dieterlen 1967b, Happold 1987). The diet is mainly green vegetation.

Oenomys hypoxanthus.

The genus is considered as closely related to *Thamnomys* (an arboreal genus), suggesting that the two genera had a common ancestor (Hatt 1940a, Lopez-Martinez *et al.* 1998). However, there are important differences in skull and molar morphology between these genera (F. Dieterlen unpubl.). Interestingly, *Oenomys* shares characters of the molar pattern with *Lamottemys* (Dieterlen & Van der Straeten 1988).

The two species are distinguished on body size, dental characters, chromosome number and geographic distribution. Variations in the

Figure 8o. Skull and mandible of *Oenomys hypoxanthus* (BMNH 26.7.6.26o).

shape and size of the molars along climatic gradients suggest the existence of an additional cryptic species in central Africa (Renaud 1999).

Fritz Dieterlen

Oenomys hypoxanthus COMMON RUFOUS-NOSED RAT (COMMON OENOMYS)

Fr. Rat à museau roux commun; Ger. Gemeine Rotnasenratte

Oenomys hypoxanthus (Pucheran, 1855). Rev. Mag. Zool. Paris, ser. 2, 7: 206. Gabon.

Taxonomy Originally described in the genus *Mus*, but assigned to *Oenomys* by Thomas (1904c) when he proposed the new genus. Shows extensive geographic variation in pelage colour and morphological characters, which has resulted in descriptions of 12 forms, either as species or subspecies (Hollister 1919, Hatt 1940a, Rosevear 1969, Dieterlen & Rupp 1976, F. Dieterlen unpubl.). Variation also occurs within populations from a single locality (Rosevear 1969). Synonyms: *albiventris*, *anchietae*, *bacchante*, *editus*, *marungensis*, *moerens*, *oris*, *rufinus*, *talangae*, *unyor*, *vallicola*. Subspecies: none. Chromosome number: $2n = 32$, $FN = 58$, $aFN = 54$ (Matthey 1963a, Maddalena *et al.* 1989).

Description Medium-sized to large slender rat with a very long tail, and rufous nose and cheeks. Pelage long (up 13 mm), dense, rather harsh. Dorsal pelage greyish-brown to rufous-brown, slightly speckled with yellowish-buff; hairs grey at base, with yellow tip or with black tip. Longer black hairs (ca. 15–23 mm, with buff tip) overlay pelage especially on mid-dorsal line. Rump and upper thighs orange or russet, contrasting with remainder of dorsal pelage. Flanks similar to dorsal pelage, sometimes with greenish-yellow tinge. Ventral pelage pure white or creamy-white, often richly suffused with orange;

clearly delineated from colour of flanks. Head similar to dorsal pelage. Nose, lips and cheeks bright orange or russet. Eyes with dark russet rings in some individuals. Ears large, rounded, covered by short reddish hairs. Vibrissae long, black. Fore- and hindfeet brown or russet, with pale claws. Tail very long (ca. 114–133% of HB), scaly and almost naked, dark above, yellowish below, with short dark bristles. Skull rather long and narrow (see also Genus profile). Nipples: usually $2+1 = 6$, but $1+2 = 6$, $2+2 = 8$ and $1+1 = 4$ in some individuals.

Geographic Variation Pelage colour varies geographically and with altitude. At lower altitudes (in Rainforest BZ), orange-russet colour on rump is darker and more extensive, and ventral pelage is strongly tinged with orange. At higher altitudes (e.g. montane forests, Rwenzori East, 2000 m), rump colouration is paler and less contrasting with colour of mid-back, and ventral pelage is whitish rather than orange/russet (Dieterlen & Rupp 1976).

Similar Species

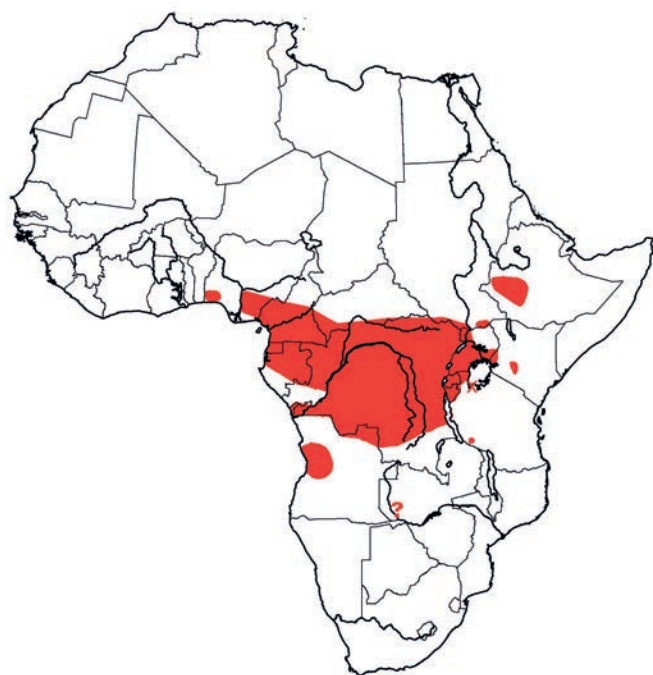

O. ornatus. On average smaller; relatively longer tail; chromosome number: $2n = 46$; occurs only to the west of the Dahomey Gap.

Grammomys spp. Smaller HB and HF; Digit 5 of hindfoot elongated; without russet colour on nose; arboreal.

Distribution Endemic to Africa. Rainforest BZ (South Central, East Central and West Central Regions) and Rainforest–Savanna Mosaics; Afromontane–Afroalpine BZ in Uganda. Recorded in Nigeria (E and W of the Niger R.), C Cameroon, Equatorial Guinea, Gabon, S Central African Republic, Congo and DR Congo. Also recorded in isolated forest patches in S Sudan, Uganda, Rwanda, Burundi, W and C Kenya, W Tanzania, N, NE and C Angola and SW Ethiopia.

Habitat Tall, moist, dense grasslands and shrubby vegetation at the edge of gallery forests, in forest clearings, along borders of marshes, farmlands, plantations and abandoned cultivation. Frequently found in elephant-grass *Pennisetum* spp. In East and central Africa, lives in dense vegetation at the edge of montane forests (2000–3000 m). On the Rwenzori Mts (Uganda) occurs in grasslands and forest from ca. 1500–2900 m, but not in bamboo or in afroalpine habitats (Kerbis Peterhans *et al.* 1998). In regions where the dry season lasts longer than 4–5 months, populations are confined to permanently moist habitats, and hence tend to be isolated from other populations. Suitable habitats are often disjunct, and hence populations also tend to be localized (Rosevear 1969). Habitats range from near sea level to ca. 3300 m (montane forest in Aberdare Range, Kenya; Hollister 1919).

Abundance Very varied. In preferred habitats may be common, e.g. in elephant-grass habitats of E DR Congo comprised up to 26% of trapped small mammals and was often the most numerous species of small mammal (Dieterlen 1967a, b). In E Nigeria, comprised 58% of small rodents ($n = 11,300$) in the herbaceous ground layer of oil palm plantations (Greaves 1964 in Happold 1987). In other seemingly suitable habitats, rare or absent.

Oenomys hypoxanthus

Adaptations Terrestrial, but also climbs in small bushes and on thick grasses; most activity is probably above ground rather than on the ground. Nests are usually constructed at 50–300 cm above ground, and are attached between thick stems of grasses or on forks or twigs of shrubs, and are rarely built on the ground (Sanderson 1940, F. Dieterlen unpubl.). Nests (diameter 12–18 cm) are woven from dry grass and other plant material; on the outside, the grasses are coarsely shredded, but inside are finely shredded. The entrance is directed slightly downwards. Nests are used as sleeping quarters and for raising the young (Rosevear 1969). Rufous-nosed Rats are diurnal and nocturnal (Dieterlen 1967c). When alarmed, they can remain motionless high up in elephant-grass, move ‘in slow motion’, or dive to the ground or even into water (F. Dieterlen unpubl.). Defecation seems to take place on the ground (F. Dieterlen unpubl.; observations in captivity). The alimentary canal is characteristic of a herbivore, the stomach and caecum being particularly large (Dieterlen 1967b, unpubl., Rahm 1972).

Foraging and Food Herbivorous. The diet (as assessed by stomach contents) of individuals living close to rainforests was primarily grass and herbs (46%), but also flesh and kernels of forest and cultivated fruits (48%), including *Carica papaya*, *Coffea robusta*, *Psidium guayava*, *Elaeis guineensis*, *Musanga cecropioides* and *Staudtia stipitata* (Genest-Villard 1980). Some stomachs contained remains of bark (30%) and invertebrates (4–5%, not insects). In E DR Congo preferred food was shoots and leaves of elephant-grass (Dieterlen 1967b). In S Cameroon, damage to bark and leaves of *Hevea* trees – formerly extensively cultivated in African rainforests – has been attributed to these rats (Jeannin 1936).

Reproduction and Population Structure In E DR Congo, reproductive activity varies with altitude and season of the year. (1) At higher altitudes (2000–2400 m), reproductive activity appears to be aseasonal and mean litter-size is 2.27. (2) At 1500–2000 m west of L. Kivu, reproduction is seasonal: 22% ($n = 100$) of adult ♀♀ were pregnant or lactating during the dry season (Jul–Sep), and 55% of adult ♀♀ were pregnant or lactating during the wet season (Oct–Jun), with a peak of 81% in Nov ($n = 254$); mean litter-size varies from 1.95 (dry season) to 2.55 (wet season), with a range (both seasons) of 1–5 (Dieterlen 1967c). (3) At 800–1000 m, in lowland rainforest habitats towards the Congo Basin, reproduction is seasonal with reduced reproductive activity during the drier months (Jul–Sep); mean litter-size 2.61 ($n = 33$; Dieterlen 1985a). In Gabon, mean litter-size: 2.54 (Dubost 1968).

Gestation: not less than 22 days; postpartum oestrus observed for some ♀♀ in captivity (F. Dieterlen unpubl.). At birth, young altricial, naked with short (ca. 1 mm) dorsal pelage and a few long yellow guard hairs (ca. 5–7 mm). Acoustical reactions and ability to crawl away and hide on Day 5–6. Eyes open Day 7–9. Lower incisors erupt Day 7–9. Nose and rump become typically rufous Day 7–9. Many behavioural characteristics (running, undirected jumping) Day 15 when ca. 15 g. Consume green plant material Day 15. Weaned by Day 30–35. Adult size: ca. 3–5 months. One captive ♀♀ produced first litter at age of 141 days. Males from lower altitudes reach maturity earlier (body weight 50–60 g) than those from high altitudes (body weight 75–80 g) (Dieterlen 1967c, 1985a). Sex ratio: 51.9% ♂♂ to 48.1% ♀♀ ($n = 1249$, E DR Congo; Dieterlen 1967a, 1985a, unpubl.).

Predators, Parasites and Diseases Predators include the Civet *Civettictis civetta*, Genet *Genetta maculata*, Palm Civet *Nandinia binotata*, Egyptian Mongoose *Herpestes ichneumon*, Green Mamba *Dendroaspis jamesoni kaimosae* and Nose-horned Viper *Bitis nasicornis* (Kenya; Allen & Lawrence 1936).

Conservation IUCN Category: Least Concern.

Oenomys ornatus WEST AFRICAN RUFOUS-NOSED RAT (WEST AFRICAN OENOMYS)

Fr. Rat à museau roux d'Afrique de l'Ouest; Ger. Westafrikanische-Rotnasenratte

Oenomys ornatus Thomas, 1911. Ann. Mag. Nat. Hist., ser. 8, 7: 378. Bibianaha, near Dunkwa, Ghana.

Taxonomy Although considered to be a valid species by Allen (1939) and Ellerman (1941), treated as a subspecies of *O. hypoxanthus* by Rosevear (1969), who commented that although the two taxa could be distinguished when viewed together, there was considerable overlap in colour and size. Karyotype and distribution are different to those of *O. hypoxanthus*. Synonyms: none. Chromosome number: 2n = 46 (with 12 meta- and submetacentric and at most 34 acrocentric chromosomes) (Tranier & Gautun 1979).

Description Medium-sized slender rat with a very long tail, and rufous nose and cheeks, similar to *O. hypoxanthus*. Dorsal pelage pale greenish-grey to greenish-brown without any tinge of rufous; hairs dark grey at base, yellow to greenish-yellow at tip. Rump bright pale rufous. Ventral pelage pure white, slightly suffused with rufous, clearly delineated by thin orange band from colour of flanks. Head similar to dorsal pelage; cheeks and nose bright rufous. Ears large and rounded with small tuft of rufous on inner front margin of ear, and rufous-red around backs and sides of ears (particularly visible in young animals). Hindlimbs rufous, as on rump. Fore- and hindfeet pale. Tail very long (ca. 132% of HB), scaly, dark above, yellowish below, with short dark bristles. Skull: see genus profile. Nipples: 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species

Oenomys hypoxanthus. HB on average larger; tail on average shorter; dorsal pelage greyish-brown or rufous-brown; chromosome number: 2n = 32; occurs only to the east of the Dahomey Gap.

Distribution Endemic to Africa. Rainforest BZ (Western Region) and western part of Northern Rainforest–Savanna Mosaic. Recorded from the Loma Mountains in Sierra Leone eastwards to Guinea, Liberia, Côte d'Ivoire and C Ghana. Not recorded from Togo (Robbins & Van der Straeten 1996) or further eastwards.

Habitat Similar to *O. hypoxanthus*. Recorded in open areas with dense undergrowth and grass in Rainforest BZ (Grubb *et al.* 1998). Also found in cultivated areas bordering rainforest in Guinea (Roche 1971).

Oenomys ornatus

Abundance Rarely encountered and considered to be rare; known only from a few localities in each of the countries where recorded (Sierra Leone [2 localities; Grubb *et al.* 1998], Guinea [9 localities; Heim de Balsac & Lamotte 1958, Roche 1971, Misonne & Verschuren 1976], Liberia [2 localities; Kuhn 1965], Côte d'Ivoire [2 localities; Tranier & Gautun 1979, Gautun *et al.* 1986] and Ghana [3 localities; Heim de Balsac & Lamotte 1958, Rosevear 1969, Grubb *et al.* 1998]). In some habitats, may be comparatively common, e.g. near Sérédou (Guinea), where 28 specimens were obtained by local collectors (Roche 1971).

Remarks Presumed similar to *O. hypoxanthus*. One nest in Guinea was made entirely from ears of rice (Roche 1971). Herbivorous (Misonne & Verschuren 1976). One specimen was identified among 374 pellets of a Barn Owl *Tyto alba* in Guinea (Heim de Balsac &

Lamotte 1958). Two juveniles (HB: 70, 72 mm) found in Jan (Ghana; BMNH).

Conservation IUCN Category: Least Concern.

Probably should be considered as Vulnerable in most parts of its range. Individuals may cause damage in some rice fields (Roche 1971).

GENUS *Pelomys*

Creek Rats

Pelomys Peters, 1852. Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin, 17: 275. Type species: *Mus (Pelomys) fallax* Peters, 1852.

Pelomys fallax.

The genus *Pelomys* contains five species widely distributed in savanna habitats in eastern and central Africa (Table 38). Species of the genus are found mainly in moist habitats and mostly near to water.

The genus is characterized by medium to large size (HB: ca. 120–170 mm), speckled or ‘pepper and salt’ dorsal pelage, with a dark mid-dorsal stripe in some species. Skull strongly built with heavy supraorbital ridges, broad interorbital constriction, a single groove on each upper incisor (as in *Myomys*) and relatively large auditory bullae. Molar teeth heavy with broad cusps, especially in the central and lingual rows (Figure 81).

Pelomys spp. are terrestrial and mainly diurnal. Preferred habitats include savanna with permanent cover of grass or bush, flood-plains, marshes, edges of bogs, and close to streams. All species in the genus require moist conditions, and hence are confined mostly to swamps and marshes in the drier parts of their geographic ranges. Although not morphologically adapted to water, two species (*P. fallax* and *P. hopkinsi*) are known to be semi-aquatic (no data for other species). They are herbivorous, feeding primarily on green vegetable material. In some localities, two species of *Pelomys* may be sympatric or parapatric (e.g. *P. fallax* and *P. campanae*) and in one locality in Angola there are probably three species (*P. campanae*, *P. fallax* and *P. minor*).

Table 38. Species in the genus *Pelomys*. Arranged in order of increasing mean head and body length.

| Species | Subgenus ^a | HB mean (range) (mm) | T mean (range) (mm) [% of HB] | Digit 5 of forefoot has | M ¹ –M ³ | Mid-dorsal stripe | Notes |
|--------------------|-----------------------|----------------------|-------------------------------|-------------------------|--------------------------------|--|---|
| <i>P. minor</i> | P | 122 (101–161) | 113 (100–131) [93%] | Nail | 5.3 (4.9–5.7) | Between ears to base of tail; thin, distinct | Central Africa south of Rainforest BZ |
| <i>P. hopkinsi</i> | K | 122 (116–127) | 164 (160–166) [135%] | Claw | 6.1 (5.8–6.6) | Centre of forehead to base of tail | Swamps near L. Victoria and Albertine Rift Valley; rare |
| <i>P. isseli</i> | K | 132 (114–149) | 149 (135–171) [113%] | Claw | 6.1 (5.9–6.3) | Forehead to base of tail; very distinct | Ssese I., L. Victoria, Uganda only |
| <i>P. campanae</i> | P | 144 (118–170) | 145 (125–158) [100%] | Nail | 6.4 (5.8–6.9) | Mid-back to base of tail; indistinct or absent | Angola, W DR Congo |
| <i>P. fallax</i> | K | 147 (125–174) | 133 (109–156) [90%] | Nail | 6.8 (6.4–7.3) | Neck to base of tail; may be indistinct | East, central and southern Africa; widespread |

^a Subgenera: K = *Komomys*; P = *Pelomys* (see genus profile for details).

Figure 81. Skull and mandible of *Pelomys fallax* (HC 2299).

Pelomys campanae ANGOLAN CREEK RAT (ANGOLAN PELOMYS)

Fr. Rat à fourrure des marais; Ger. Angolanische Bachratte

Pelomys campanae (Huet, 1888). Le Naturaliste, ser. 2, 10 (31): 143. Landana, west coast of Angola.

Taxonomy Originally described in the genus *Golunda*. Subgenus *Pelomys*. Probably evolved from a peripheral population of the more widely distributed *P. fallax* through isolation by invasive Kalahari sands in S DR Congo (Crawford-Cabral 1983). Synonyms: none. Chromosome number: $2n = 48$, FN uncertain, probably ca. 60 (Matthey 1963a).

Description Distinctive, medium-sized species, similar in overall size to *P. fallax*. Dorsal pelage similar to *P. fallax* (see that species profile). Black mid-dorsal stripe from mid-back to base of tail (in ca. 70% of specimens); indistinct in some individuals. Ventral pelage dull white, yellowish-white or honey-yellow, delineated from colour of flanks. Reddish-yellow patches on neck and ventral surface in some (mostly subadult) individuals. Hairs on nasal region, ears and around eyes rusty-brown. Forefoot with five digits: Digits 2, 3 and 4 normal, Digit 1 very small (almost invisible), Digit 5 small, bearing a nail (as in *P. fallax*). Hindfoot with five digits; Digits 2, 3 and 4 long, Digits 1 and 5 short, not reaching base of other digits; all with short claws. Tail long (ca. 100% of HB), colour variable, mostly darkish above, paler below, bristles short above, slightly longer laterally and below. Skull similar to *P. fallax*, but more delicately built, with less developed median row of cusps (t2, t5, t8) on M^1 and M^2 . Each upper incisor with groove. Nipples: $2 + 2 = 8$.

The genus is a member of the arvicanthine group of species (Musser & Carleton 2005), which also includes *Arvicanthis*, *Desmomys*, *Lemniscomys*, *Mylomys* and *Rhabdomys*. Morphologically it is closely related to *Mylomys* and *Desmomys*. Two subgenera may be recognized (F. Dieterlen unpubl.): (a) subgenus *Pelomys*: tail equal or less than HB, mid-dorsal stripe incomplete or absent, margin of ears without black hairs, and Digit 5 of forefoot relatively short with a nail; (b) subgenus *Komemys*: tail longer than HB, mid-dorsal stripe complete, margin of ears with black hairs, and Digit 5 of forefoot relatively long with claw. Subgeneric distinctions are not recognized by Musser & Carleton (2005).

Species are distinguished by size, relative length of tail, presence/absence of mid-dorsal stripe, and presence of nail or claw on Digit 5 of forefoot.

Fritz Dieterlen

Geographic Variation None recorded.

Similar Species

P. fallax. Mid-dorsal stripe mostly shorter or lacking; ventral pelage usually buff or yellowish; tail shorter (ca. 90% of HB); skull more robust; median row of cusps on M^1 and M^2 well developed.

Distribution Endemic to Africa. North-western part of Zambezi Woodland BZ and Southern Rainforest–Savanna Mosaic. Recorded from Angola, mostly west of 16°E and from ca. 07°S to 17°S including the Cabinda enclave, and from W and SW DR Congo, from the mouth of the Congo R. eastwards to the catchment of the Kwango, Kwilu and Kasai rivers to about 06°S and 23°E . Northernmost locality is Bolobo on the Congo R. Occurs sympatrically or parapatrically with *P. fallax* in parts of its range (Crawford-Cabral 1983).

Habitat Grassland savannas. Sometimes occurs close to but never inside rainforests. In Angola (including Cabinda), occurs on the coastal plains, the Escarpment zone and on the Western Angolan plateau. Also found in old gardens, and in local cornfields with grassy patches (field notes on museum labels). Juveniles (HB: ca. 75 mm) found in Apr, Jun and Jul (Angola; BMNH).

Pelomys fallax (Peters, 1852). Monatsb. K. Preuss. Akad. Wiss. Berlin 17: 275. Caya district, Zambezi River, Mozambique.

Taxonomy Originally described in the genus *Leggada*. Subgenus *Pelomys*. Because there is considerable variation in size and pelage colour, Musser & Carleton (2005) suggest that *P. fallax* may contain more than one species. The most distinctive forms (which may represent one or more valid species or subspecies, e.g. *frater* in parts of Angola) occur at the margins of the geographic range of the species (F. Dieterlen unpubl.). Synonyms: *australis*, *concolor*, *frater*, *insignatus*, *iridescens*, *luluae*, *rhodesiae*, *vumbae*. Subspecies: none. Chromosome number: not known.

Description Large species, similar in size and colour to *Arvicanthis* spp. Largest species of the genus. Pelage glossy, speckled, with a greenish-brown or olive iridescence. Dorsal pelage golden-yellow to rusty-brown; hairs dark blackish-grey at base, yellow at tip; interspersed with thick black guard hairs, black or yellowish-brown at tip. Mid-dorsal black stripe from neck to base of tail, clearly defined or indistinct, but usually conspicuous in juveniles. Base of tail dull rusty-brown. Ventral pelage variable, usually buff or yellowish anteriorly, dirty-white in axillary and inguinal regions. Head similar in colour to dorsal pelage. Ears sparsely covered with short rufous hairs. Nasal region sometimes rufous. Forefoot with four digits: Digit 1 absent or vestigial; Digits 2, 3 and 4 long, with long claws; Digit 5 very short with nail. Hindfoot with Digits 2, 3 and 4 long with long claws; Digits 1 and 5 short with short claws. Tail long (ca. 90% of HB), black above, whitish below. Skull strongly built with heavy supraorbital ridges, broad interorbital constriction, and relatively large auditory bullae. In most specimens, anterior palatal foramina reach to level of M¹, but not in some populations. Each upper incisor

with groove. Molar teeth heavy with broad cusps, especially in the central and lingual rows. Nipples: 2 + 2 = 8.

Geographic Variation In many parts of its range *P. fallax* shows a relatively large variation in size and pelage colour. The population of *rhodesiae* in the SW corner of its geographic range (SW Zambia and Caprivi Strip) is a distinct form (F. Dieterlen, unpubl.). The typical *iridescens* is distributed in SE Kenya and NE Tanzania. Large areas within the distribution of *P. fallax* – C and S Tanzania, N Mozambique, Malawi, most of Zambia, most of S DR Congo and parts of Angola – have indistinctive forms assigned to *insignatus* and *vumbae*.

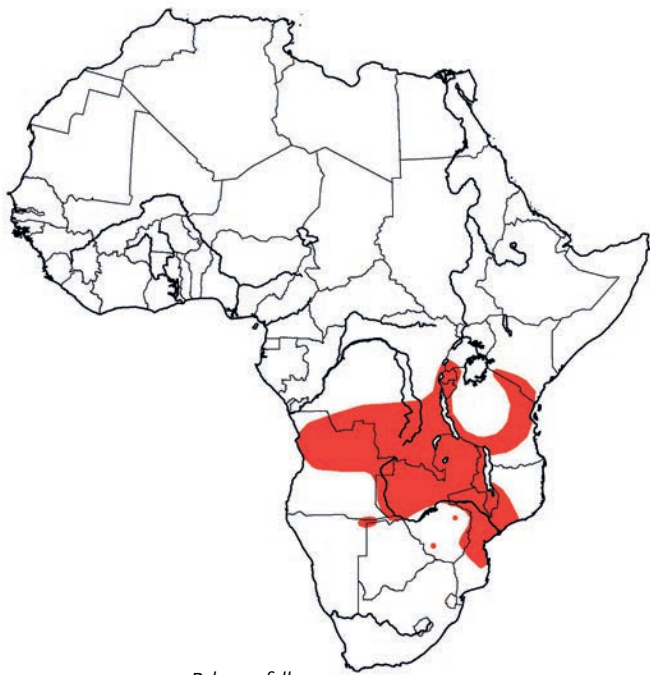

Similar Species

P. campanae. Mid-dorsal stripe distinct (in most individuals); ventral pelage whitish; tail on average longer; median row of cusps on M¹ and M² slightly smaller.

P. hopkinsi. Digit 5 of forefoot with claw.

Arvicanthis spp. Some forms have a slight mid-dorsal stripe; rostrum and nasal region narrower; incisors not grooved; nipples 1 + 2 = 6.

Distribution Endemic to Africa. Zambezian Woodland BZ (north of the Zambezi R.) and Southern Rainforest–Savanna Mosaic; also Afromontane–Afroalpine BZ of central Africa. The most widespread of all species in the genus. Recorded from S Kenya, SW Uganda, Tanzania, Rwanda, Burundi, E and S DR Congo, N Angola, Zambia, Malawi, Mozambique, N Botswana, N Zimbabwe and NE Namibia (Caprivi Strip). Wide altitudinal distribution: in N Tanzania 150–2400 m (Hubbard 1972), and in E DR Congo up to 2000 m and

*Pelomys fallax*

also in open grassy montane areas at higher altitudes (F. Dieterlen unpubl.).

Habitat Generally restricted to savanna habitats with permanent cover of grass or bush or cultivation. In regions where some parts of the year are dry, confined to permanent damp habitats, e.g. flood-plain grasslands, marshes, edges of bogs, stream sides, the perimeter of forests, and all habitats 'where access to water is possible throughout the year and where the overhead shelter is not normally destroyed by fire' (Vesey-Fitzgerald 1966). In regions where the wet season is long (up to nine months of the year, e.g. SW Uganda, E DR Congo), distribution is more or less continuous and populations are not restricted to swamps and marshes, etc.; in such localities, recorded from stands of *Pennisetum* and other grasslands, swampy secondary bush and dense cultivation (Dieterlen 1967a, Rahm 1967).

Abundance Not rare, but never abundant, in the cultivated habitats west of L. Kivu, E DR Congo. In dense elephant-grass, and in more open grassy bushland, numbers estimated at ca. 3% of the small mammal community (5 spp., $n > 100$; Dieterlen 1967a, c).

Adaptations Terrestrial, nocturnal and diurnal. Activity may vary with habitat: in Botswana, where occurs only in swampy areas, it is almost entirely diurnal (Smithers 1971); in Uganda, where the environment is generally moist, they are considered as 'equally diurnal and nocturnal' (Delany 1975). The colouration and pattern of the pelage appears to provide excellent camouflage during daylight hours. Runs quickly and hides under grass. In southern Africa, they dig their own burrows, often in dry ground adjacent to wet places (Smithers 1983). In contrast, in dense grasslands of E DR Congo, the thick layer of rotten vegetation provides excellent shelter. Nests of grass are either built amongst grass debris, or in burrows. In the Okavango swamps, Shortridge (1934) recorded that individuals were 'often observed sunning themselves like water voles on the fringe of

the reed-beds, now and again taking short plunges into the water from one patch of vegetation to another. They were rather wary and on alarm disappeared behind the reeds'. In moister habitats, they are parapatric with *Otomys* spp., and in drier habitats with *Lemniscomys* spp. and *Arvicanthis* spp.

Foraging and Food Mainly herbivorous. Feeds on leaves, shoots, stems of various grasses and swamp vegetation, often leaving behind small piles of cut grass stems (a behaviour also seen in some other species of grass-eating rodents). Stomach contents in cultivated areas contained green vegetation – green stems, leaves and pods of beans, but also grains of sorghum and whitish matter of tubers etc. May also feed on seeds (Smithers 1983). In Malawi, contents of three stomachs contained only green vegetation, one contained white material (presumably from seeds) and one contained insect remains (Hanney 1965).

Social and Reproductive Behaviour Little information. Captive animals are docile and communal (Hanney 1965). Nests where young were found in E DR Congo were made of very finely shredded grass, mostly situated under rotten vegetation or in very large tussocks of elephant-grass (*Pennisetum purpureum*).

Reproduction and Population Structure Reproductive activity occurs throughout most of the year near L. Kivu, E DR Congo, without any clear relationship to wet and dry seasons. Most births occurred in Jan–Jul when 58% of adult ♀♀ were reproductively active ($n = 26$); activity declined in Aug–Dec when 33% of adult ♀♀ were reproductively active ($n = 15$). In Botswana and Zimbabwe, reproduction occurred in the warmer and wetter months between Aug and Apr (Smithers 1971, 1975). Gestation: not known. Embryo number: 5.45 (4–7, $n = 11$; DR Congo; Dieterlen 1967c). Embryo number: 2 and 7 (Nyika Plateau, Malawi; Hanney 1965). Nests found with complete litters in Kivu, E DR Congo, had 3–7 young. Development as follows (mean values from two litters; F. Dieterlen unpubl.). Day 1–2: HB: 40 mm, WT: 2.8 g; skin darkly pigmented with fluffy yellowish hairs (1 mm). Day 4–5: HB: 46 mm, WT: 4.5 g. Day 7–8: HB: 52 mm, WT: 5.1 g, dorsal stripe visible, lower incisors erupting (0.5 mm). Day 10: eyes open. Day 22: HB: 73 mm, WT: 13.5 g. Day 65: HB: 119 mm, WT: 50 g, scrotum visible in ♂♂. Day 105: HB: 140 mm, WT: 78 g, adult pelage fully developed.

Predators, Parasites and Diseases Predators include owls (several records of remains in owl pellets from Malawi; Hanney 1965) and genets (Hubbard 1972). Heavily parasitized, more so than most other species of small mammals near L. Kivu, DR Congo. Most free-living young supported many fleas. Subadults and adults were often infested with larvae of bot-flies (*Cordylobia* sp.), up to 10 mm long, under the skin near the base of tail, on the belly and on the neck (F. Dieterlen unpubl.). In Malawi, parasitized by nematodes *Longistriata* sp., cestodes *Inermicapsifer guineensis*, and fleas *Ctenophthalmus calceatus*, *Dinopsyllus lypusus* (Hanney 1965). In Tanzania, six species of fleas reported – the two spp. listed above, *D. longifrons*, *C. blandulus*, *C. verutus* and *C. evidens* (Hubbard 1972). Reported to be plague-positive in East Africa (Hubbard 1972). Parasitized by 11 spp. of mites (from four families) and 13 spp. of fleas (from three families) in southern Africa (Zumt 1961, details in De Graaff 1981).

Conservation IUCN Category: Least Concern.

Pelomys hopkinsi HOPKINS'S CREEK RAT (HOPKINS'S PELOMYS)

Fr. Rat à fourrure de Hopkins; Ger. Hopkins Bachratte

Pelomys hopkinsi Hayman, 1955. Rev. Zool. Bot. Afr. 52: 323. Rwamachuchu, Gombolola, Rukiga County, Kigezi District, Uganda.

Taxonomy Subgenus *Komemys*. Morphologically similar to *P. isseli*, but differences in pelage colouration, skull, distribution and habitat distinguish the two species. Synonyms: none. Chromosome number: not known.

Description Small to medium-sized speckled rat with a long tail. Dorsal pelage blackish, speckled with tawny or ochraceous; hairs dark blackish-grey at base with tawny or yellowish tip; some hairs thicker, pure black. Distinct black mid-dorsal stripe running from the centre of the forehead to base of tail, usually contrasting conspicuously with the blackish speckled pelage. Ventral pelage variable, but usually slate-grey with buff tinge; hairs grey on basal half, yellow or buff on terminal half. Inner surface of ears with short rufous hairs; outer surface of ear pale except for contrasting band (2–3 mm wide) of black hairs on upper outer surface. Nasal region gingery-orange. Limbs and feet similar in colour to dorsal pelage; soles of feet blackish (cf. *P. isseli*). Digit 5 of forefoot with claw. Tail very long (ca. 135% of HB), blackish above, paler or dirty white below. Each upper incisor with groove. Nipples: 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species

P. isseli. Pelage not dark-coloured; soles of feet not blackish.

Distribution Endemic to Africa. Eastern Rainforest–Savanna Mosaic. Recorded mostly between L. Victoria and the Albertine Rift Valley: Kigesi in SW Uganda (1 specimen), S and C Rwanda (5) and W Kenya (2).

Habitat Swamps. The holotype was collected at the edge of a papyrus swamp in Kigezi, Uganda. Of five specimens from Rwanda, four are also from the edge of papyrus swamps in the catchment area of the Akanyaru and Kagera rivers (Hayman 1955, Misonne 1965a).

Abundance Rare; known only by eight specimens.

Remarks Presumed to be adapted to the swampy environment, and to be semi-aquatic. Apparently no other information available.

Conservation IUCN Category: Data Deficient.

Schlitter (1989) classified it as Vulnerable 'because of the tenuous nature of its preferred habitat and the small area of occurrence'.

Pelomys hopkinsi

Pelomys isseli SSESE ISLANDS CREEK RAT (LAKE VICTORIA PELOMYS)

Fr. Rat à fourrure des Iles Ssese; Ger. Ssese Inseln Bachratte

Pelomys isseli (De Beaux, 1924). Annali Mus. Civ. Stor. Nat. Giacomo Doria 51: 207. Kome I., L. Victoria, Uganda.

Taxonomy Subgenus *Komomys*. Morphologically similar to *P. hopkinsi*, but significant distinguishing traits suggest that *P. hopkinsi* and *P. isseli* should be treated as separate species (Afework Bekele & Schlitter 1989). Synonyms: none. Chromosome number: not known.

Description Medium-sized buffy slightly speckled rat with a very long tail; externally looks very similar to *Lemniscomys rosalia*. Dorsal pelage warm tawny-buff slightly speckled with black; hairs blackish at base, buff or tawny at tip. Very distinct black mid-dorsal stripe from forehead to base of tail; base of tail rusty. Ventral pelage brownish-grey tending to yellowish-grey on flanks; neck grey. Margins of ears bordered with black hairs (2–3 mm long). Hairs orange, yellowish or rusty on the nose, around the eyes and at base of ears. Digit 5 of forefoot with claw (cf. *P. fallax*). Soles of feet not (or only slightly) blackish (cf. *P. hopkinsi*). Tail very long (ca. 113% of HB), blackish above, yellowish below. Each upper incisor with groove. Nipples: not known.

Geographic Variation None recorded.

Similar Species

P. hopkinsi. Blackish pelage, black mid-dorsal stripe not contrasting conspicuously with the blackish pelage; soles of feet blackish.

Lemniscomys rosalia. Dorsal pelage orangey-brown to dark brown with obvious thin mid-dorsal black stripe; tail shorter (ca. 130 mm, 100% of HB); Digit 5 of forefoot with nail; each upper incisor without groove.

Distribution Endemic to Africa. Recorded from some of the Ssese Is. (Kome, Bugala, Bunyama) in NW L. Victoria, Uganda. It is the only species of *Pelomys* on the islands, and is not known from the mainland where *P. hopkinsi* and *P. fallax* are present. It has not been recorded on other islands of the archipelago.

Habitat The collecting habitat on Bugala I. was abandoned farmland covered with herbs and perennials. The species was not found in forest, nor in natural grassland (Delany 1969, 1975); unlike *P. hopkinsi* on the mainland of Uganda, it does not show a preference for swamps.

Abundance Comprised 13% of rodents of the rodent community (5 spp.) in abandoned farmland on Bugala I. (n = 30; Delany 1969).

Remarks Two lactating ♀♀ and one ♀ with four placental scars

*Pelomys isseli*

was found in Apr (the only month of sampling) (Delany 1969).

Conservation IUCN Category: Data Deficient.

Schlitter (1989) classified it as Vulnerable because it occurs only on three islands in L. Victoria.

***Pelomys minor* LEAST CREEK RAT (LEAST PELOMYS)**

Fr. Rat à fourrure plus petit; Ger. Kleine Bachratte

Pelomys minor Cabrera & Ruxton, 1926. Ann. Mag. Nat. Hist., ser. 9, 17: 601. Luluabourg, DR Congo.

Taxonomy Subgenus *Pelomys*. Synonyms: none. Chromosome number: not known.

Description Small rat with a long tail; the smallest species in the genus. Dorsal pelage similar in colour to *P. fallax* and *P. campanae*. Black mid-dorsal stripe, usually thin but distinct, from between ears to base of tail; indistinct in some individuals. Base of tail dull rusty-brown, not always distinguishable from colour of mid-back. Ventral pelage dull white, buff or yellowish. Hairs on nasal region, ears, at base of ears and around eyes rusty-brown. Digit 5 of forefoot very short, with nail. Hindlimbs rusty; hindfeet yellowish-buff. Tail long (ca. 93%, but may be $\geq 100\%$), blackish above, grey below. Each upper incisor with groove. M^1 – M^3 short (mean 5.3 mm), much shorter than in *P. fallax* and *P. campanae* (see Measurements). Nipples: not known.

Geographic Variation None recorded.

Similar Species

P. fallax. On average larger in most respects; M^1 – M^3 longer.

P. campanae. On average larger; M^1 – M^3 longer.

Lemniscomys rosalia and *L. griselda*. Black mid-dorsal stripe; each upper incisor without groove: M^1 – M^3 longer (ca. 6.2 mm); cusps of upper molars relatively small and low.

Distribution Endemic to Africa. Zambezian Woodland BZ and Southern Rainforest–Savanna Mosaic. Recorded from NE Angola (8 localities), N Zambia (4), SW, C and E DR Congo (11) and W Tanzania (1) (F. Dieterlen unpubl.). In one locality in N Angola (Duque de Braganca) appears to be sympatric with *P. fallax* and *P. campanae*.

Habitat Moist savanna, e.g. savanna with tall grass, near to cultivated land, on slopes near rivers and in wooded valleys (Sanborn 1952). Highest locality is Ujamba, Mahari Mts, W Tanzania, ca. 2160 m in montane grassland (where grass is ca. 3 ft high).

Remarks Juvenile (HB: ca. 75 mm) caught in Aug (Angola; BMNH). Apparently no other information available.

Conservation IUCN Category: Least Concern.

GENUS *Praomys***Soft-furred Mice**

Praomys Thomas, 1915. Ann. Mag. Nat. Hist., ser. 8, 15: 4. Type species: *Epimys tullbergi* Thomas, 1894.

The genus *Praomys* is endemic to tropical Africa and is here considered to contain 16 species (but see also below) (Table 39). Most species in the genus live in primary rainforest, secondary forest, gallery forests in savanna habitats, and montane forests, over a range of altitudes from near sea level to 3000 m. Some may also occur in forest plantations, and

some species may be found in agricultural fields and in dense grasslands in and close to rainforests. Only one species, *P. daltoni*, lives in savanna habitats (where the closely related genera *Myomyscus* and *Mastomys* are common), and only one species, *P. derooi*, lives in commensal habitats in savanna (where it may cohabit with *Mastomys* spp. and *Rattus rattus*).

Praomys tullbergi.

Members of the genus are called ‘Soft-furred Mice’ because of their smooth dense soft pelage. They are medium-sized (ca. HB: 100–130 mm, WT: 30–60 g) with brown to reddish-brown or greyish-brown dorsal pelage, and grey or white ventral pelage. The muzzle is pointed, ears are large and naked, hindfoot is neither short and broad as in *Hylomyscus*, nor long and elongated as in *Malacomys*, and the tail is long and more-or-less naked. The dorsal surface of the mouth has seven or nine palatal ridges, and there are six plantar pads on the sole of the hindfoot (cf. five pads in *Malacomys*). The skull is elongated, with a narrow interorbital constriction and a marked supraorbital ridge above each orbit; the palatine bone extends well forward to end level with M¹ (cf. *Myomyscus* [= *Myomys*] and *Mastomys*) and long

Figure 82. Skull and mandible of *Praomys tullbergi* (HC 673).

anterior palatal foramina extend posteriorly to the level of the first row of cusps of M¹ (cf. *Malacomys*). Incisor teeth are opisthodont and cheekteeth are rather small (Figure 82). There are usually 1 + 2 = 6 nipples (sometimes 2 + 2 = 8 in *P. degraaffi*).

Table 39. Species in the genus *Praomys*. Arranged in order of increasing mean head and body length. (n. d. = no data.)

^aT = *tullbergi* species-group. J = *jacksoni* species-group. D = *delectorum* species-group. L = *lukolelae* species-group. R = *daltoni* species-group.

Soft-furred Mice are often the most numerous of terrestrial small mammals in African forests (e.g. forming up to 75% of individuals in a community of seven species). Two species (*P. tullbergi*, *P. jacksoni*) have very widespread distributions, others (*P. rostratus*, *P. delectorum*) are less widespread, and some have very restricted distributions (e.g. *P. morio* on Mt Cameroon and *P. hartwigi* on montane habitats in Cameroon, and *P. degraaffi* on mountains of the Albertine Rift Valley). In many localities there is only one species of *Praomys*, but in some localities in central Africa there may be at least three species of *Praomys* living parapatrically and/or syntopically. They are terrestrial and nocturnal. During the day they hide under logs and within the crevices of buttress roots. The diet is mainly fruits and seeds that fall to the forest floor, new green shoots and occasionally insects. They are social, unaggressive animals; home-ranges tend to be small and to overlap extensively, and there is no indication of territoriality. Reproduction (for those species that are well studied) is seasonal, with peaks in pregnancy rate during the wet season and early dry season. Litter-size is large (usually 3–5, but up to eight), ♀♀ have a postpartum oestrus, and reproductive rate is high.

The taxonomy of the genus is controversial and has been the subject of debate for many years. The definition of the genus, and its constituent species, is still uncertain. Historically, species have been variously placed in the genera *Mus*, *Rattus* and *Epimys* (Rosevear 1969), and the genus *Praomys* has included species now considered to represent *Hylomyscus*, *Mastomys* and *Myomys* (e.g. Misonne 1974). In recent years, the recognition of 'cryptic species' (as a result of new methods of analysis and more extensive sampling) has resulted in descriptions of additional

species of *Praomys*. Hence the number of species in the genus has varied from 21 (with four subgenera) (Misonne 1974) to nine (Musser & Carleton 1993) to 15 (Musser & Carleton 2005). Many authors have used the term 'Praomys-complex' to refer to these four closely related taxa. How these genera are viewed taxonomically is determined, to some extent, by the type of analysis. For example, Van der Straeten & Dieterlen (1983), using canonical analysis, considered *Myomys*, *Mastomys* and *Myomyscus* as subgroups or subgenera within *Praomys*, whereas Chevret *et al.* (1994), using DNA/DNA hybridization experiments, considered that *Mastomys* and *Hylomyscus* are independent genera, and that *Praomys* and *Myomys* are closely related and may be synonymous. However, there now seems to be general consensus (Lecompte *et al.* 2002a) that *Praomys*, *Myomys* (now *Myomyscus*), *Hylomyscus* and *Mastomys* are independent genera, although the relationships between and within these genera are not yet well understood.

Within the genus *Praomys* (as understood here), five species-groups can be distinguished on the basis of karyology, number of palatal ridges and cranial characters: three species-groups (a, b, c) were listed by Lecompte *et al.* (2002a, b), Van der Straeten & Kerbis Peterhans (1999) and E. Van der Straeten (pers. comm.). In addition, Van der Straeten & Duda (1990) recognize a fourth species-group (d), and a fifth species-group (e) is included for species formerly in *Myomys*. These species-groups are:

- (a) *tullbergi* species-group (*P. tullbergi*, *P. hartwigi*, *P. misonnei*, *P. morio*, *P. rostratus*, *P. obscurus*, *P. petteri*): palatal ridges 2 + 7 = 9; plantar pads 6; anterior palatal foramina reach to front edge of first root of M¹; t3 of M¹ obsolete or difficult to detect; weak supraorbital ridges not raised. Chromosome number: 2n = 34 (*P. tullbergi*, *P. morio*, *P. rostratus*); 2n = 42 (*P. petteri*). Habitat usually primary rainforest.
- (b) *jacksoni* species-group (*P. jacksoni*, *P. mutoni*, *P. minor*, *P. degraaffi*): palatal ridges 2 + 5 = 7; plantar pads 6; anterior palatal foramina reach to middle of first root of M¹; t3 of M¹ well developed; supraorbital ridges raised. Chromosome number: 2n = 28 (*P. jacksoni*). Habitat usually secondary forest and more open habitats.
- (c) *delectorum* species-group (*P. delectorum* only): palatal ridges 2 + 5 = 7; plantar pads 6; smaller size than other groups; anterior palatal foramina reach to front edge of first root of M¹; t3 of M¹ well developed; t3 in M² larger than in other species of *Praomys*; weak supraorbital ridges not raised. Chromosome number: 2n = 48. Habitat only montane forest in eastern Africa.
- (d) *lukolelae* species-group (*P. lukolelae*, *P. verschureni*): palatal ridges 2 + 5 = 7; plantar pads 6; anterior palatal foramina short not reaching to M¹; t3 on M¹ obsolete; weak supraorbital ridges not raised. The long hindfoot, long ears and the form of the skull are more typical of *Malacomys* than of *Praomys*. Chromosome number: 2n = 58 (*P. verschureni*). Habitat rainforest.
- (e) *daltoni* species-group (*P. daltoni*, *P. derooi*): palatal ridges 2 + 5 = 7; plantar pads 6; anterior palatal foramina reach to front edge of first root of M¹; t3 of M¹ well developed; supraorbital ridges not raised. Chromosome number: 2n = 36. Habitat savanna (*P. daltoni*) and houses (*P. derooi*). These species were formerly allocated to *Myomys* (= *Myomyscus*).

The *Praomys*-complex is considered to be monophyletic (as are the closely related genera *Hylomyscus*, *Praomys*, *Myomyscus* [= *Myomys*])

| Chromosome number | Notes |
|---------------------|---|
| n. d. | Savanna; commensal. West Africa |
| 2n = 48 | Montane forests. East Africa |
| n. d. | Rainforest. DR Congo (south bank of Congo R.) |
| 2n = 34 | Rainforest and forest relicts. West Africa (Gambia to Central African Republic) |
| 2n = 26, FN = 28 | Montane forests of Albertine Rift Valley. Burundi, Rwanda, Uganda |
| 2n = 36 | Savanna. Senegal to SW Sudan |
| n. d. | Rainforest. E and NE DR Congo |
| 2n = 34 | Montane forest at higher altitudes. Mt Cameroon only |
| 2n = 34 | Rainforest. Senegal to Ghana |
| n. d. | Rainforest. DR Congo (N of Congo R.) |
| 2n = 28, FN = 30 | Rainforest and forest relicts. Central Africa |
| 2n = 42, FN = 62 | Rainforest. Cameroon, Gabon, Congo |
| n. d. | Gallery montane forest. E Nigeria (Gotel Mts) |
| 2n = 58, FN = 58/60 | Rainforest and sub-montane forest. DR Congo (north and east of Congo R.) |
| n. d. | Rainforest. DR Congo (south of Congo R.). Similar to <i>Malacomys</i> |
| n. d. (? 2n = 34) | Gallery montane forest. Cameroon (near L. Oku only) |

and *Mastomys*) (Lecompte *et al.* 2002a). About 3–4 mya, the ancestral lineage is thought to have diverged to form the four taxa (here considered as genera) (Chevret *et al.* 1994). At this time, the climate was hot and humid, and forests were expanding. It is hypothesized that later, 3–3.5 mya, a cooler, drier period led to the expansion of savanna and fragmentation of the forests into a mosaic of isolated forest patches (the largest of which may be termed ‘forest refuges’). Some populations adapted to the savanna habitats and evolved into the genera *Myomyscus* (= *Myomys*) and *Mastomys*; others remained in forest patches and evolved into *Hylomyscus* and into the *tullbergi* species-group and *jacksoni* species-group. The present distribution of species is a result of these climatic events. Some species occur only around a former refuge, e.g. *P. rostratus* in Upper Guinea; *P. morio* and *P. hartwigi* in the mountainous regions of Cameroon; *P. misonnei* and *P. mutoni* in the central Congo Basin (although the distribution of these species is not fully known);

P. degraaffi in the mountains of the Albertine Rift Valley; and *P. delectorum* in montane regions of E Africa (Lecompte *et al.* 2002a; see also Happold & Happold 1989b, Happold 1996). Other species (*P. jacksoni*, *P. tullbergi*) are more widespread, due perhaps to greater habitat tolerance, but also to dispersal when rainforests expanded after the Pleistocene. The genus *Praomys* is now considered as paraphyletic (Lecompte *et al.* 2002a). Further investigations may show that *P. jacksoni* and perhaps *P. tullbergi* (as now understood) are comprised of a complex of different species (E. Van der Straeten unpubl.).

The species in the genus are distinguished by size, locality, pelage colour (to some extent) and cranial characteristics. However, some species are very difficult to identify by external characteristics, and can be distinguished only by special methods of craniometry.

Praomys daltoni DALTON’S SOFT-FURRED MOUSE (DALTON’S PRAOMYS)

Fr. Souris sylvestre de Dalton; Ger. Daltons Weichhaarmaus

Praomys daltoni (Thomas, 1892). Ann. Mag. Nat. Hist., ser. 6, 10: 181. West Africa (see Rosevear 1969).

Taxonomy Originally described in the genus *Myomys*. Species-group: *daltoni*. Traditionally referred to as *Myomys daltoni*. Now allocated to the genus *Praomys* on the basis of morphological (Musser & Carleton 2005), molecular (Lecompte *et al.* 2002b) and DNA/DNA hybridization (Chevret *et al.* 1994) data. Constitutes a separate species-group with *P. derooi* (= *Myomys derooi*). Synonyms: *butleri*, *ingoldbyi*, *saturatus*, *tuareg*. Subspecies: none. Chromosome number: 2n = 36, all autosomes acrocentric (Granjon *et al.* 1992 and unpubl.).

Description Small savanna mouse with pure white ventral pelage. Dorsal pelage variable in colour, from yellowish-brown in the Sahel Savanna BZ to chocolate-brown near the Rainforest BZ; hairs grey at base, brown at tip. Ventral pelage pure white, clearly delineated from dorsal pelage on flanks and cheeks. Ears fairly large, oval-shaped. Eyes relatively small. Back of fore- and hindfeet white. Hindfeet rather short, with a short Digit 5 and a relatively long Digit 1. Tail long (ca. 110% of HB), with small scales arranged in rings, almost naked. Skull: anterior palatal foramina reach to front edge of first root of M¹; t3 of M¹ well developed; supraorbital ridges not raised. Nipples: 3 + 2 = 10.

Geographic Variation None recorded.

Similar Species

P. derooi. Slightly smaller on average (especially in skull and dental measurements); ventral pelage uniformly grey; commensal.

P. tullbergi and *P. rostratus*. Ventral pelage grey; tail and hindfoot on average longer; rainforest habitats.

Distribution Endemic to Africa. Widespread in Sahel, Sudan and Guinea Savanna BZs and Rainforest–Savanna Mosaic close to the edge of the Rainforest BZ. Recorded in most West African countries from Senegal to S Chad, N Central African Republic and SW Sudan.

Habitat Rocky hillsides, inselbergs, open dry forest and savanna habitats where grass and often rocks are present. Often found near or in human settlements, in gardens or cultivated farms (Rosevear 1969; Happold 1975b). In Nigeria, preferred habitat is Guinea Savanna; it is less numerous in savannas of the Rainforest–Savanna Mosaic and Sudan Savanna BZ and has not penetrated ‘savanna-like’ habitats in the Rainforest BZ (cf. *Mus musculoides*, *Lemniscomys striatus*) (Happold 1987). An ability to cope with human-modified environments undoubtedly accounts for the northward extension of the geographic range as far north as the Adrar des Iforas Massif in Mali (Dobigny *et al.* 2001a).

Praomys daltoni

Abundance In W Nigeria, comprised 0–78% (mean 50%) of small rodents at 11 localities, and at six of these localities it was the commonest species (Happold 1975b). Especially abundant on inselbergs throughout Nigeria in the Guinea Savanna BZ (Happold 1987). Populations of Dalton's Mice fluctuate during the year; in the savannas of the Rainforest–Savanna Mosaic in S Nigeria, highest population numbers occurred in the mid-late dry season (8–10/ha) and the lowest in the mid wet season (3–4/ha) (Anadu 1973). At Foro, Côte d'Ivoire, comprised 24% of small mammals, the second most numerous species after *Lemniscomys zebra* (Gautun 1975). In SE Senegal, densities ranged from 0 to 20/ha during a 3-year study (Bâ 2002).

Adaptations Nocturnal, with a main peak of activity during the first half of the night in captivity (Duplantier & Granjon 1990). Often considered arboreal, and said to have its nests in tree holes or even under the bark (Hubert *et al.* 1973). Displays good swimming performances under laboratory conditions (Duplantier & Bâ 2001).

Foraging and Food Predominantly granivorous; insects (mainly termites) also eaten at the beginning of the dry season. In Senegal, seeds of *Trianthema portulacastrum* (Ficoidaceae) are preferred at any season (Moro & Hubert 1983).

Social and Reproductive Behaviour Lactating ♀♀ show considerable maternal care, and ♂♂ may assist with the care of the young. Observations in captivity suggest that *M. daltoni* is a territorial species (Anadu 1979a).

Reproduction and Population Structure The period of reproduction varies at different localities. At Foro in C Côte d'Ivoire, pregnant and lactating ♀♀ were observed in Feb–Jul and in Sep–Nov, with periods of quiescence in Jan–Feb and Aug–Sep. The length of each period of reproduction varied annually (during a 3-year period), but there was no clear relationship with rainfall (Gautun 1975). In Nigeria, reproduction occurred throughout the year, with peaks at the beginning and the end of the wet season (Anadu 1979a). In SE Senegal, pregnant ♀♀ were recorded in the dry season (Apr and Jun), and the highest proportion of young were present in November, about one month after the end of the wet season (Bâ 2002). Gestation: 23 days. Monthly means of 3.0–6.5 embryos/

female in Côte d'Ivoire (Gautun 1975). Litter-size (in captivity): 5.6 (3–10, $n = 13$; Anadu 1978); young weaned during Week 3; age at sexual maturity 4.5–5.5 months; interval between successive litters 21–37 days (mean = 29.1; Anadu 1979a). Individuals recaptured up to 21 months after their initial capture in Senegal (Bâ 2002).

In SW Nigeria (Anadu 1973), proportion of each of three age-classes fluctuated seasonally. In mid wet season (Jul–Oct) population comprised mostly adults (80–100% of population); juveniles first appeared in Oct, reached a peak in numbers (80–100% of population) in early dry season (Dec), by which time many adult animals had left the population (and are presumed to have died). By mid-late dry season (Jan–Apr), juveniles had become subadults. A second peak of juveniles occurred during early wet season (May–Jun), the progeny of old adults and perhaps some of the youngest adults (born 6–7 months previously). Population turnover 1–2 times each year.

Predators, Parasites and Diseases In Senegal, present but rare in pellets of Barn Owls *Tyto alba* (Granjon *et al.* unpubl.).

Conservation IUCN Category: Least Concern.

Praomys degraaffi DE GRAAFF'S SOFT-FURRED MOUSE (DE GRAAFF'S PRAOMYS)

Fr. Souris sylvestre de De Graaff; Ger. De Graaffs Weichhaarmaus

Praomys degraaffi Van der Straeten and Kerbis Peterhans, 1999. S. Afr. J. Zool. 34: 81. Abris Nyamugari, Burundi. 2200 m.

Taxonomy Species-group: *jacksoni* (Van der Straeten & Dudu 1990). Distinguished from *P. jacksoni* by pelage colour, number of nipples and karyology (Van der Straeten & Kerbis Peterhans 1999). Synonyms: none. Chromosome number: $2n = 26$, $FN = 28$ (Maddelena *et al.* 1989, as *Praomys cf. jacksoni*). One pair of acrocentric chromosomes fewer than in *P. jacksoni*.

Description Medium-sized mouse, with overall dark pelage. Overall pelage typically dark grey or sooty-black. Hindfoot with

six large plantar pads (usual murid arrangement) and usually one small accessory plantar pad; hindfoot narrow (cf. *P. jacksoni*). Tail very long (ca. 129% HB). Skull: supraorbital ridges well developed and straight, originating at anterior end of frontal bone; t3 of M¹ well developed; posterior limit of anterior palatal foramina level with second root of M¹. Nipples: 2 + 2 = 8.

Geographic Variation None recorded.

Similar Species

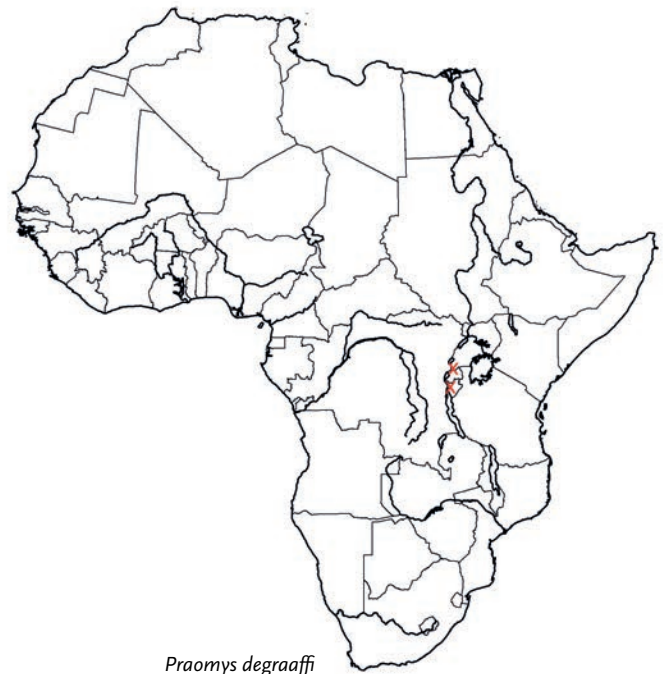

P. jacksoni. Dorsal pelage grey or rufous; nipples 1 + 2 = 6; chromosome number $2n = 28$; HF broader (mean 4.6 mm); four accessory plantar pads; may be syntopic at 1800–2500 m; widespread geographic distribution.

Distribution Endemic to Africa. Afroalpine–Afroalpine BZ. Recorded from mountainous regions bordering the eastern side of the Albertine Rift Valley in Burundi (Bururi F. R., 1880–2170 m; Kibira N. P.), Ruanda (Nyungwe N.P.; Parc National des Volcans) and Uganda (Mgahinga Gorilla N. P.; Bwindi Impenetrable N. P.; Echuya F. R.). Occurs at successively lower altitudes with increasing latitude (Van der Straeten & Kerbis Peterhans 1999). In certain localities at high altitude (e.g. 2680 m in Mgahinga N. P. and 2380 m in Echuya F. R.), the only member of the genus. In Bwindi Impenetrable N. P., it is sympatric with *P. jacksoni* at 2350 m but it has not been found at lower altitudes (1500–1850 m) where *P. jacksoni* is the sole representative of the genus.

Habitat High altitude montane forests. In Echuya F. R. prefers thick stands of bamboo, secondary herbaceous growth, edges of fast-flowing streams, dense shrubs in wet forest and, on one occasion, *Rubus* habitats between Echuya Swamp and bamboo forest. In Mgahinga Gorilla N. P. consistently but infrequently occurs in monodominant stands of *Hagenia* and in patches of *Myrianthus* sp. In Bwindi Impenetrable N. P. it prefers the dry slopes at high altitudes (2350 m) rather than wet valley bottoms. In S Burundi favours secondary forest above 2000 m and primary forest and open valleys dominated by *Entandophragma*.

Abundance Varies according to locality and vegetation, becoming more common with increasing altitude. Comprised 16% of captured small mammals in and near Echuya Forest (Van der Straeten & Kerbis Peterhans 1999) and 6–7% in Mgahinga Gorilla N. P. at ca. 2680 m. Especially common in southern localities, where it comprised 40% (Bururi F. R., Burundi; 2000 m) and 54% (Mumushwizi Valley, Kibira N. P., Burundi) of small mammals.

Remarks Nocturnal and terrestrial. Pregnancies were recorded in Feb (1 of 2 adult ♀♀; Kibira N. P.), Mar (1 of 5; Bururi F. R.), Apr (1 of 4) and Aug (1 of 6; Bururi F. R.). None of the ♀♀ collected in March (n = 18) in Kibira N. P. was pregnant. No information for other months. Embryo number: 2 (n = 1), 4 (n = 3).

Praomys degraaffi

Conservation IUCN Category: Vulnerable.

***Praomys delectorum* DELICATE SOFT-FURRED MOUSE (EAST AFRICAN PRAOMYS)**

Fr. Souris sylvestre délicate; Ger. Reizende Weichhaarmaus

Praomys delectorum (Thomas, 1910). Ann. Mag. Nat. Hist., ser. 8, 6: 430. Mulanje Plateau, Malawi.

Taxonomy Species-group: *delectorum*. Described in the genus *Epimys* (Thomas 1910d). Synonyms: *melanotus*, *octomastis*, *taitae*. Van der Straeten & Kerbis Peterhans (1999) recognized these forms as valid species but, following Musser & Carleton (2005), they are considered to be synonyms here. Subspecies: none. Chromosome number: $2n = 48$ (as *taitae*; Matthey 1965).

Description Small delicate mouse with soft, smooth, dense pelage. Dorsal pelage dark brown from nose to base of tail, dorsal hairs dark

brownish-grey with dark brown tips; hairs of flanks tipped with rusty-brown. Flanks slightly paler. Ventral pelage whitish-grey; ventral hairs dark grey, whitish-grey at tip. Chin and throat similar to ventral colouration. Head narrow, with pointed nose, long black vibrissae and large eyes. Ears elongated, rounded at tips, dark brown; very mobile, held upwards and forwards from head. Fore- and hindlimbs short and slender, with sparse short white hairs; four digits on forefeet (Digit 1 almost vestigial); five digits on hindfeet (Digit 1 short). Tail very long (ca. 125% of HB), thin, with many small dark scales and

short dark bristles. Skull: supraorbital ridges small (or absent), originating half way along frontal bone; posterior limit of anterior palatal foramina at second root of M^1 ; t_3 of M^1 well developed. Palatal ridges $2 + 5 = 7$. Nipples: $2 + 2 = 8$.

Geographic Variation None recorded.

Similar Species This is the only species of *Praomys* on the mountains of eastern Africa.

Distribution Endemic to Africa. Afroalpine–Afroalpine BZ of eastern Africa. Disjunct, confined to riverine and montane forests above ca. 1500 m. Recorded from Malawi (Cholo Mt, Mlanje Mt, Zomba Plateau, Dedza Mt, Vipya Plateau, Nyika Plateau, Misuku Hills); Tanzania (Mt Kilimanjaro, Mt Meru, Ngorogoro Crater, Southern Highlands, Uzungwa Mts, Uluguru Mts, Usambara Mts); Zambia (Makutu Mts, Mafinga Mts); Mozambique (Namuli Mt) and SE Kenya (Shimba Hills) (Swynnerton & Hayman 1951, Hanney 1965, Ansell 1978, Rodgers *et al.* 1982, Ansell & Dowsett 1988, Happold & Happold 1992). May also occur on other highlands of the Eastern Arc Mountains in Tanzania.

Habitat Montane forests, riverine forests and tangles along margins of forests in highland regions where average annual rainfall is not less than ca. 2000 mm. May occur in bracken adjacent to forest, mostly during the wet season, but rarely found in grassland adjacent to forest even when grasses are tall and dense. This species shows a statistically significant preference for montane forest habitats compared with all other montane habitats (grasslands, bracken, etc.) (Happold & Happold 1989b, c).

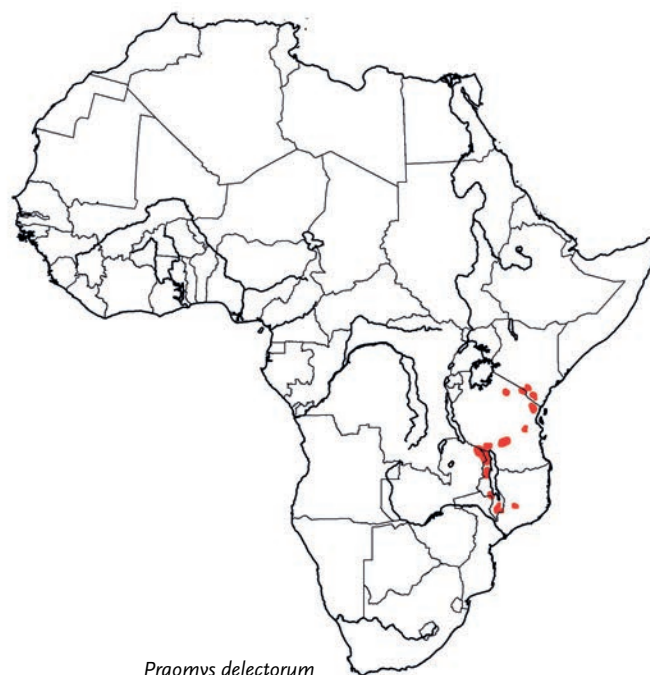

Abundance Common in suitable habitats, especially at the end of the breeding season (see below). Comprised 29–33% of small mammals trapped in forest/grassland mosaic habitats and 50–88% in montane forest habitats in Malawi (Happold & Happold 1989b, c, 1992).

Adaptations Terrestrial and scansorial. Nocturnal. Lives in burrows amongst the roots of large forest trees, and under large logs.

Foraging and Food Forages on ground in leaf-litter. Omnivorous. Analyses of stomach contents: 78% contained vegetable material, 82% contained insects (caterpillars, adult insects) ($n = 45$, Malawi; Hanney 1965).

Social and Reproductive Behaviour No information. Individuals in captivity do not exhibit agonistic behaviour (D. C. D. Happold, unpubl.).

Reproduction and Population Structure Pregnancies during late dry season and wet season (Sep–Apr) but mostly in Dec–Feb (Malawi). On Zomba Plateau, Malawi, young animals enter population during late wet season and early dry season (Feb–Apr). Litter-size usually 4 (2–6). Population numbers (on Zomba Plateau)

Praomys delectorum

low at end of dry season (Aug–Nov), increasing to maximum (up to $\times 10$ minimum) at end of wet season and beginning of early dry season (Mar–Jun); young form 50–80% of population in late wet season. Individuals rarely survived for more than six months (Happold & Happold 1989c).

Predators, Parasites and Diseases Preyed upon infrequently by African Grass-owls *Tyto capensis* on Zomba Plateau, Malawi, probably only during the wet season when they move into bracken at the forest edge (Happold & Happold 1986), and when they climb to the top of grass stalks to feed on the seed heads.

Conservation IUCN Category: Least Concern.

Because of restricted habitat requirements, populations on separate highland areas are isolated from other populations.

Praomys derooi DE ROO'S SOFT-FURRED MOUSE (DE ROO'S PRAOMYS)

Fr. Souris sylvestre de De Roo; Ger. Deroos Weichhaarmaus

Praomys derooi Van der Straeten and Verheyen, 1978. Z. Säugetierk. 43: 33. Borgou, Togo.

Taxonomy Species-group: *daltoni*. Traditionally referred to as *Myomys derooi*. Now allocated to the genus *Praomys* (see also the phylogenetically closely related *P. daltoni*). Considered a commensal form of *Myomys daltoni* (now *Praomys daltoni*) by Heim de Balsac (1967a) and Rosevear (1969), before being described as a new species by Van der Straeten & Verheyen (1978b). In contrast, Musser & Carleton (2005) suggest that this species may represent local populations of *P. daltoni*. Synonyms: none. Chromosome number: $2n = 36$, all autosomes acrocentric (Granjon 1992, L. Granjon unpubl.).

Description Small brownish commensal mouse. Dorsal pelage variable in colour, from pale brown to dark grey-brown; hairs grey at base with brown tip. Flanks paler than the back, with a gradual transition to the uniformly grey ventral pelage. White spot often present on chest. Tail long (115–120% of HB), unicoloured, with rather long hairs, especially in the mid-dorsal region and at tail tip. Skull: see *P. daltoni*. Palatal ridges $2 + 7 = 9$. Nipples: $3 + 2 = 10$.

Geographic Variation None recorded.

Similar Species

P. daltoni. Larger on average (especially in skull and dental measurements); ventral pelage pure white; natural savanna habitats.

P. tullbergi and *P. rostratus*. On average longer tail and hindfoot; ventral pale grey, hairs with white tip; rainforest habitats.

Mastomys spp. On average larger; ♀♀ with up to 24 nipples equally spaced along abdomen; natural savanna and commensal habitats.

Distribution Endemic to Africa. Guinea Savanna BZ. Recorded from Ghana, Togo, Benin and W Nigeria (Van der Straeten & Verheyen 1978b, Happold 1987, Decher *et al.* 1997). Also possibly Guinea (one juvenile ♂; Ziegler *et al.* 2002; but see Musser & Carleton 2005).

Habitat Commensal in savanna habitats (Van der Straeten & Verheyen 1978b).

Abundance Locally abundant, although not present in many areas.

Remarks Appears to be a rather highly specialized commensal species. May live sympatrically in human dwellings and stores with *Rattus rattus* and *Mastomys erythroleucus*. Reproductive data available only for Jul, Aug, Nov and Dec. Pregnant ♀♀ recorded in each of these months (wet season and early dry season); pregnancy rates: Jul 11% ($n = 27$ adult ♀♀), Aug 28% ($n = 7$), Nov 20% ($n = 5$), Dec 39% ($n = 66$); lactating ♀♀ in Jul, Aug and Dec. Many juveniles

*Praomys derooi*

in Dec. Embryo number: 3.75 (2–5) (Van der Straeten & Verheyen 1978b). Because of commensal habits, reproduction may occur during a longer period of the year than present records indicate.

Conservation IUCN Category: Least Concern.

Praomys hartwigi HARTWIG'S SOFT-FURRED MOUSE (HARTWIG'S PRAOMYS)

Fr. Souris sylvestre de Hartwig; Ger. Hartwigs Weichhaarmaus

Praomys hartwigi Eisentraut, 1968. Bonn. Zool. Beitr. 19: 8–11. L. Oku, Bamenda Highlands, Cameroon.

Taxonomy Species-group: *tullbergi* (Lecompte *et al.* 2001, Lecompte *et al.* 2002a), as indicated by its palatal ridges (Fülling 1992). Synonyms: none. Chromosome number: not known (presumably $2n = 34$; Eisentraut 1970).

Description Medium-sized dark reddish-brown rodent. Pelage soft and long (13–15 mm on back). Dorsal pelage rich dark reddish-brown or russet-brown; hairs dark grey with reddish-brown tip. Flanks similar, less rich. Ventral pelage whitish-grey; hairs grey at base, off-white at tip. Head similar to dorsal pelage. Lips and lower cheeks greyish or pale russet. Chin and throat greyish-white. Forefeet whitish, five digits; Digit 1 reduced to tubercle with very small claw. Tail very long (ca. 140% of HB), medium brown, ringed with scales, appears more or less naked but covered with very small dark bristles. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

P. obscurus. Similar in external measurements and pelage texture, but dorsal pelage darker and skull smaller; occurs only in the Gotele Mts, Nigeria.

P. jacksoni. On average smaller in external and cranial measurements; pelage long and less soft; occurs sympatrically with *P. hartwigi* on Mt Oku.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from Mt Oku and L. Manengouba in the Bamenda Highlands, Cameroon (Eisentraut 1970, Hutterer *et al.* 1992).

Habitat Strictly confined to montane forest habitats. Mainly found on the forest floor, but may climb on trees and branches (O. Fülling pers. comm.).

Abundance Common in the undisturbed montane forest slopes of Mt Oku.

Remarks Terrestrial and nocturnal. Limb proportions suggest adaptations to a scansorial life. Omnivorous; up to 10% of stomach contents are animal remains, such as arthropods and worms. Animals forage mainly on the ground. Hunted with traps and eaten by the local Oku people (all information: O. Fülling pers. comm.).

Praomys hartwigi

Conservation IUCN Category: Endangered.

Praomys jacksoni JACKSON'S SOFT-FURRED MOUSE (JACKSON'S PRAOMYS)

Fr. Souris sylvestre de Jackson; Ger. Jacksons Weichhaarmaus

Praomys jacksoni (de Winton, 1897). Ann. Mag. Nat. Hist., ser. 6, 20: 318. Entebbe; Uganda.

Taxonomy Originally described in the genus *Mus*. Species-group: *jacksoni*. The definition of this species is problematic because the holotype is a juvenile with insufficient data, and the species currently

regarded as '*P. jacksoni*' may include other forms or species. Van der Straeten & Dudu (1990) used topotype specimens in order to define the species, and proposed that those with a karyotype of $2n = 28$,

FN = 30 and AA = 26 represent *P. jacksoni*. Van der Straeten & Dudu (1990) and Van der Straeten & Kerbis Peterhans (1999) regard *montis* (from Uganda), *peromyscus* (from Kenya), *sudanensis* (from Sudan) and *viator* (from Nigeria) as valid species on the basis of canonical analysis; in contrast Musser & Carleton (2005) refer these to synonyms of *P. jacksoni*. Synonyms: *montis*, *peromyscus*, *sudanensis*, *viator*. Subspecies: none. Chromosome number: $2n = 28$, FN = 30.

Description Small rufous-grey soft-furred mouse, similar in external appearance to several other species of the genus. Pelage soft and long (9–10 mm). Dorsal pelage grey or rufous (see below), hairs dark grey at base, grey or rufous at tip. Dorsal pelage varies with age: dark grey in juveniles and subadults, rufous in adults and deep rufous in old adults. Changes in colour due to age less pronounced in montane populations, where the dorsal pelage is mostly darker. Ventral pelage greyish-white, hairs grey at base, white at tip. Forefeet whitish. Hindfeet pale with brownish tinge, comparatively wide (4.6 mm; cf. *P. degraaffi*); toes whitish. Ears relatively large, round, darkish, inconspicuously haired. Tail very long (ca. 118% [Uganda] to 140% [Nigeria]), almost naked, dark grey above, slightly paler below. Skull: supraorbital ridges well developed and straight, originating at anterior end of frontal bone; posterior limit of anterior palatal foramina at second root of M^1 ; $t3$ of M^1 well developed. Palatal ridges: $2 + 5 = 7$. Nipples $1 + 2 = 6$.

Geographic Variation None recognized here, but see Taxonomy.

Similar Species

- P. misonnei*. $t3$ on M^1 absent; interorbital breadth small (especially when compared with *P. jacksoni*); partly sympatric; restricted geographic range.
- P. tullbergi*. Palatal ridges $2 + 7 = 9$; supraorbital ridges weak or absent; sympatric in parts of range; widespread and common; allopatric.
- P. mutoni*. On average slightly smaller; rare; partly sympatric.

Praomys jacksoni

Hylomyscus spp. HF usually shorter and broader; tail relatively longer; scansorial and arboreal; widespread and common.

Distribution Endemic to Africa. Rainforest BZ (East Central and South Central Regions) and rainforest relicts in Rainforest–Savanna Mosaics from Nigeria to Kenya and Tanzania. Widespread in DR Congo, S Central African Republic, Gabon and Equatorial Guinea (Rio Muni). Also recorded in Afromontane–Afroalpine BZ as follows: Nigeria (Jos Plateau, Abuja, Gotele Mts, Mambilla Plateau; Happold 1987, Hutterer *et al.* 1992), Cameroon (Adamaoua Highlands and western montane regions; Eisentraut 1975, Hutterer & Joger 1982) and Tanzania (Eastern Arc mountains). Altitudinal range: ca. 300 m in lowland rainforest to ca. 3000 m in montane forests (e.g. Mt Tshiaberimu, Virunga N. P., DR Congo [3000 m; Verschuren *et al.* 1983], Mt Kinyetti, S Sudan [3187 m; F. Dieterlen unpubl.] and Mt Elgon, Uganda [3250 m; Clausnitzer & Kityo 2001]). Probably absent from the alpine and sub-alpine zones of mountains.

Habitat Primarily lowland rainforest and secondary forest; also recorded in cultivated and fallow land, montane forests and rainforest relicts in Rainforest–Savanna Mosaics. Occasionally lives in bamboo forest and around marshes and swamps.

Abundance One of the most common species of small mammal in the rainforests of central and eastern Africa. In montane forests of E DR Congo (1900–3300 m), comprised 28.9% of small rodents and was often the most abundant species ($n = 2043$; F. Dieterlen unpubl.). At lower altitudes in E DR Congo, abundance varied: overall the most numerous (19%) of 14 species, ranging from 14% (rainforests) to 20% (forested hills) and 21% (abandoned farmland in rainforest) (Rahm 1972). In Mayanga Forest, Uganda, was the second most numerous species (28%, as *P. morio*) after *Lophuromys flavopunctatus* (51%) (Delany 1971).

Adaptations Terrestrial, nocturnal and crepuscular. May also scramble over dead logs and tree stumps and climb small branches up to ca. 2 m (6 ft) and very occasionally higher (Delany 1971). Activity is primarily nocturnal (ca. 89% of captures), and occasionally diurnal (ca. 11%) ($n = 293$; E DR Congo; Rahm 1972). Runways are made under debris and tree roots. Nests are built under roots and are constructed of cut grasses and ferns (Rahm 1967). The alimentary canal is typical of an omnivore: it is long (about 6.5 times length of head and body) and has the following proportions: small intestine 85%, caecum 5%, large intestine 10% ($n = 18$, Clausnitzer 2003; see also Rahm 1972).

Foraging and Food Mainly frugivorous; partly omnivorous. Forages mainly on the ground, as described by Vesey-Fitzgerald (1966): ‘The home-range of a group may be restricted to the vicinity of a single forest tree such as *Parinari*, which sheds its fruit on the ground. It collects the fruit by making sorties from a convenient shelter. The fruit is then carried back to the shelter, where the hard shell is gnawed at leisure in order to get at the kernel; the debris of continual feeding indicates that such shelters are used during a prolonged period possibly amounting to the life span of several generations.’

The diet is mainly seeds, nuts, kernels and fruits. In E DR Congo, 31 out of 38 stomachs contained vegetable material, and only two

stomachs were full of insects – mainly *Pseudacanthotermes* termites (Rahm 1972). Analysis of 54 stomachs (F. Dieterlen unpubl.) in E DR Congo showed the following: most (44) contained vegetable material, mainly kernels and pulp from fruits; 11 contained sorghum from nearby cultivations; 20 contained small amounts of insects; and ten contained large numbers of insects – mostly ants and other invertebrates. Few stomachs (5%) contained fresh green plant material. On Mt Elgon, diet was seeds and fruit pulp, with some arthropods and herbs (Clausnitzer 2003).

Social and Reproductive Behaviour Little information. Females nipple-drag their young when disturbed or alarmed (F. Dieterlen unpubl.).

Reproduction and Population Structure Reproduction occurs during many months of the year in relation to rainfall and the availability of fruits. In lowland rainforests (Irangi, E DR Congo; 800–1000 m), reproductively active ♀♀ (as assessed by pregnancy and/or lactation) comprised, on a yearly basis, 65% of adult ♀♀, rising to 71% during wet season (Sep–Mar) with peak in Dec–Feb, and falling to 46% during dry season (Jun–Aug). In montane forests of E DR Congo (1900–2700 m), equivalent percentages were 56%, rising to 68% (n = 234) in Jan–Apr, and falling to 39% in May–Jun. In both lowland and montane regions, reproductive activity of ♂♂ (assessed by length of testes) showed a similar and corresponding trend to that of ♀♀ (F. Dieterlen unpubl.).

Gestation: uncertain – 25–31 days (F. Dieterlen unpubl.); 36 (34–37) days (Delany 1971). Embryo number varies according to locality. In lowland forests of DR Congo: 3.18 (1–5, n = 91), increasing to 3.68 in Dec–Jan. In montane forests: 3.60 (1–6,

n = 215; F. Dieterlen unpubl.). At other localities, litter-size: 3.0 (Kisangani, C DR Congo; Dudu 1991), 3.33 (1–5, n = 67; Uganda; Delany 1971) and 3.8 (2–6, n = 11; Gabon; Dubost 1968). At birth, young altricial, blind, naked and with some dorsal pigmentation; weight ca. 2.5 g. Short pelage present Day 10. Eyes open and limb coordination Day 10–16. Weaned by Day 29 (just before ♀ has next litter). Testes fully formed in ♂♂ by Day 74. Males first copulate at ca. Day 85, and first parturition in ♀♀ about Day 112 (Delany 1971). Females have a postpartum oestrus.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.
Widespread and common; not threatened at present.

Praomys lukolelae LUKOLELA SOFT-FURRED MOUSE (LUKOLELA PRAOMYS)

Fr *Souris sylvestre* de Lukolela; Ger. Lukolele-Weichhaarmaus

Praomys lukolelae Hatt, 1934. Amer. Mus. Novit. 708:13. Lukolela, Central African Republic.

Taxonomy Originally described as *Praomys tullbergi lukolelae*. Species-group: *lukolelae*. Exhibits characteristics of both *Malacomys* and *Praomys*. Long hindfeet, large naked ears and elongated face suggest affinities to *Malacomys*; six plantar pads on hindfoot and some characteristics of cranium and teeth suggest affinities to *Praomys*. Sometimes included in genus *Malacomys* (e.g. Musser & Carleton 1993; Leirs *et al.* 1999), but now considered to belong to *Praomys* (Musser & Carleton 2005). Probably closely related to *P. verschureni*. The similarities between *P. lukolelae* and *P. verschureni* suggest a close relationship; together they may represent a new genus, distinct from *Praomys* and *Malacomys* (E. Van der Straeten pers. comm.). Synonyms: none. Chromosome number: not known.

Description Medium-sized russet-brown rodent, with long hindfeet and large naked ears. Pelage lies close to body; without a velvet texture as in *Malacomys* spp. Dorsal pelage medium-brown or russet-brown, paler on flanks; hairs grey at base, brown terminal band. Ventral pelage whitish-grey; hairs grey at base, white at tip. Head with elongated muzzle; ears relatively large, brown, naked, rounded at tip. Pre- and subauricular spot, pinkish-cinnamon. Limbs and feet whitish-grey.

Hindfoot long and slender; six plantar pads (as in *Praomys* spp.; cf. five in *Malacomys*). Tail long (ca. 115% of HB), mostly naked, dark above, pale below. Skull: supraorbital ridges small, not raised; posterior limit of anterior palatal foramina anterior to M¹ (as in *Malacomys*); t3 on M¹ absent. Palatal ridges 2 + 5 = 7. Nipples: not known

Geographic Variation None recorded.

Similar Species

P. verschureni. Similar in many characters; NE DR Congo only; probably allopatric.

Praomys (other spp). Ear length shorter relative to GLS; on average T and HF shorter.

Malacomys longipes. Larger (HB: ca. 158 mm, HF: ca. 39 mm); pelage similar in texture to velvet; five plantar pads on hindfoot; sometimes parapatric.

Distribution Endemic to Africa. Rainforest BZ (South Central Region). Known only from Lukolela, Kikwit and SE of Kisangani, DR Congo. Perhaps more widespread than these records suggest.

*Praomys lukolelae*

Habitat Rainforest.

Abundance Uncertain; very local. At Kikwit, formed 1.9% of all small mammals collected in forest and grassland habitats ($n = 1879$) (Leirs *et al.* 1999).

Remarks Terrestrial and nocturnal. No other information available.

Conservation IUCN Category: Least Concern.

Distribution restricted, and no detailed information on conservation status. Destruction of rainforest is likely to be a major threat.

Praomys minor LEAST SOFT-FURRED MOUSE (LEAST PRAOMYS)

Fr. Souris sylvestre plus petite; Ger. Kleine Weichhaarmaus

Praomys minor Hatt, 1934. Amer. Mus. Novit. 708: 11. Lukolela, DR Congo.

Taxonomy Species-group: *jacksoni*. Described as a subspecies of *P. jacksoni* but now treated as a distinct species (Van der Straeten & Dudu 1990). Synonyms: none. Chromosome number: not known.

Description Small mouse. Dorsal pelage warm brown in older individuals, dark brown in younger ones. Flanks paler. Ventral pelage whitish-grey; hairs grey at base, white at tip. Dark eye-ring. Palatal ridges $2 + 5 = 7$. Hands and feet white. Some ♂♂ have a white patch or stripe just in front of the penis. Tail very long (ca. 120–130% of HB), unicoloured, dark brown, with a few short hairs between the scales. Some animals have irregular pale spots on the tail. Skull: supraorbital ridges well developed and straight, originating at anterior end of frontal bone; posterior limit of anterior palatal foramina at second root of M^1 ; t_3 of M^1 well developed. Nipples $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

P. jacksoni. On average larger; HF on average longer (mean 25 mm).

P. lukolelae. On average much larger; HF longer (mean 30.2 mm).

*Praomys minor*

Distribution Endemic to Africa. Rainforest BZ (South Central Region). Recorded only from the type locality on the left bank of the Congo R., DR Congo.

Erik Van der Straeten

Praomys misonnei MISONNE'S SOFT-FURRED MOUSE (MISONNE'S PRAOMYS)

Fr. Souris sylvestre de Misonne; Ger. Misonnes Weichhaarmaus

Praomys misonnei Van der Straeten and Dieterlen, 1987. Stuttgart. Beitr. Naturk., Serie A, 402: 3. Irangi, Kivu, DR Congo.

Taxonomy Species-group: *tullbergi*. Closely related to *P. tullbergi*, *P. rostratus* and *P. morio*. In E DR Congo, occurs sympatrically with *P. jacksoni*, from which it can be distinguished by characters of the skull (Van der Straeten & Dieterlen 1987, Van der Straeten & Dudu 1990). Musser & Carleton (1993, 2005) point out that *P. misonnei* could simply be a form of *P. tullbergi* at the eastern margin of its geographical range, but Van der Straeten & Dieterlen (1987) found highly significant differences in ten skull and tooth characters. The specimens of *P. misonnei* from Kenya, identified as such by Qumsiyeh *et al.* (1990), are now considered to represent a new species, *P. degraaffi* (Van der Straeten & Kerbis Peterhans 1999). Synonyms: none. Chromosome number: not known.

Description Small rufous soft-furred mouse, similar in external appearances to *P. jacksoni*. Pelage soft and long (9–10 mm). Dorsal pelage rufous or grey; hairs dark grey at base, rufous or grey at tip. Dorsal pelage varies with age: dark grey in subadults, rufous in adults and deep rufous in old adults. Ventral pelage greyish-white; hairs grey at base, white at tip. Forefeet whitish and hindfeet pale with whitish tinge, toes whitish. Tail very long (ca. 123% of HB), almost naked, dark grey above, slightly paler below. Skull: similar to *P. tullbergi*; the most obvious distinction is the narrower breadth of M¹ and the narrower interorbital breadth compared with *P. jacksoni*; supraorbital ridges absent or small (if present, originate half-way along frontal bone); posterior limit of anterior palatal foramina at anterior edge of M¹; t3 of M¹ absent or difficult to detect. Palatal ridges 2 + 7 = 9. Nipples 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species

P. jacksoni. HB on average slightly larger; tail slightly longer; palatal ridges 2 + 5 = 7; skull characters as for *jacksoni* species-group; sympatric.

Distribution Endemic to Africa. Rainforest BZ (East Central Region). Recorded only from Irangi, Masako Forest (near

Kisangani), Ituri Forest and Gamangui, all in E and NE DR Congo (Van der Straeten & Dudu 1990, Dudu 1991). Extent of range unknown but likely to occur in most of the lowland and sub-montane rainforest of E DR Congo. Possibly occurs in some localities in Uganda and W Kenya (not mapped). A record by Nicolas & Colyn (2003) of '*Praomys cf. misonnei*' at Mont Doudou, SW Gabon (02° 09' S, 10° 30' E) is much further west than other records and needs investigation.

Habitat Similar to that of *P. jacksoni*. Recorded from lowland rainforest (500–850 m) at Masako and Irangi, and sub-montane forest (up to 1650 m) at Irangi. Has not been found at higher

Praomys misonnei

altitudes, e.g. in montane forest (1800–3000 m) in Kahuzi–Biega N. P. Preferred habitat is undisturbed rainforest, although may also occur (less frequently) in secondary forest and fallow cultivated habitats within rainforest; never found in wet areas (cf. *P. mutoni*).

Abundance Abundance varies according to habitat and altitude. In general, not nearly as common as the sympatric *P. jacksoni*. In lowland rainforest at Irangi (altitude 850–950 m), *P. misonnei* was less numerous (27%, $n = 103$) than *P. jacksoni* (73%, $n = 282$), but in the sub-montane rainforest above Irangi at 1250–1650 m, it was more numerous (78%, $n = 54$) than *P. jacksoni* (22%, $n = 17$) (F. Dieterlen unpubl.). It was never found at higher altitudes in the montane forest (1800–3000 m) in Kahuzi–Biega N. P.

Remarks Mostly terrestrial but also semi-arboreal. Reproductive activity mostly during the wet season: 80% of adult ♀♀ ($n = 21$) were pregnant or lactating during the wet season (Sep–May; $n = 21$); and only 7% during the dry season (Jun–Aug; $n = 15$) (Dieterlen 1985a, b). Embryo number: 3.2 (2–5, $n = 14$ litters). Sex ratio: 3:2 ($n = 150$).

Conservation IUCN Category: Least Concern.

Although recorded from only a few localities, this species is likely to be fairly widespread in rainforests.

Measurements

Praomys morio CAMEROON SOFT-FURRED MOUSE (CAMEROON PRAOMYS)

Fr. Souris sylvestre du Mont Cameroon; Ger. Kamerun-Weichhaarmaus

Praomys morio (Trouessart, 1881). Bull. Soc. Etudes Sci. Angers 10: 121. Mount Cameroon, Cameroon. 7000 ft (2135 m).

Taxonomy Originally described in the genus *Mus*. Species-group: *tullbergi*. Attempts to breed *P. morio* with *P. tullbergi* in captivity were unsuccessful (Eisentraut 1973), indicating that *P. morio* is specifically distinct. The name *morio* has been used for specimens from localities far from Mt Cameroon (e. g. in Central African Republic), but these are now known to represent *P. tullbergi* or *P. petteri* (Musser & Carleton 1993, 2005). Synonyms: *maurus*. Subspecies: none. Chromosome number: $2n = 34$ (same as *P. tullbergi*; Matthey in Eisentraut 1973).

Description Small dark montane forest mouse. Pelage dense and soft, dorsal hairs 10–12 mm. Dorsal pelage dark rufous-brown to blackish-brown; hairs dark grey at base, rufous-brown to dark brown at tip. Ventral pelage pale to dark grey; hairs dark grey at base, white at tip; colour of base often shows through to surface. Ears relatively long, darkly pigmented, rounded at tip. Head, cheeks, muzzle and throat similar to dorsal pelage. Fore- and hindlimbs dark brown. Tail very long (ca. 112% of HB), darkly pigmented, with small dark bristles. Skull similar to *P. tullbergi*: supraorbital ridges small or absent, originating half way along frontal bone; posterior limit of anterior palatal foramina at anterior edge of M¹; t3 of upper M1 absent or difficult to detect; rostrum shorter and narrower and M¹–M³ longer than in *P. tullbergi* (Eisentraut 1969b, Lecompte *et al.* 1999). Palatal ridges $2 + 7 = 9$. Nipples: $1 + 2 = 6$.

Geographic Variation Specimens from lower altitudes are rufous-brown to dark brown; those from higher altitudes are darker and blacker because there is more melanin in the hairs. Specimens from Bioko I. tend to be slightly smaller, on average, to those from Mt Cameroon (Eisentraut 1970).

Similar Species

P. tullbergi. HB on average smaller (mean 103 mm); T on average longer (mean 145 mm); M¹–M³ shorter (mean 4.5 mm); widespread in rainforests of West Africa.

P. jacksoni. T on average longer (mean 146.9 mm); GLS and M¹–M³ similar; palatal ridges $2 + 5 = 7$; chromosome number: $2n = 28$; widespread in rainforests of central Africa.

Praomys morio

P. hartwigi. T longer; GWS and M^1 – M^3 larger; only known from Mt Oku and L. Manengouba in the Bamenda Highlands of Cameroon.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from Mt Cameroon and Bioko I. On Mt Cameroon, known from ca. 1000–3000 m, but not recorded at lower altitudes on the mountain nor on neighbouring mountains at similar altitudes. On Bioko I. recorded at 1200–2000 m. Appears not to be syntopic or sympatric with *P. tullbergi*.

Habitat Montane forest at higher altitudes, and alpine grasslands towards the summit of Mt Cameroon.

Abundance Uncertain; tends to be more abundant at higher altitudes.

Remarks Probably similar to *P. tullbergi* in most respects. Gestation: 26–30 days. Females have a postpartum oestrus. Embryo number (Mt Cameroon): 4.6 (3–6); mode 5, $n = 14$ litters. Litter-size (in captivity): 4.7 (2–6), mode 4 and 5, $n = 61$. Weight at birth: 2.25–2.64 g. Eyes open on Day 17–19. Growth

to 25 g in ca. 80 days. Minimum age to first conception: 136 days (Eisentraut 1961).

Conservation IUCN Category: Endangered.

The limited distribution of the species and destruction of rainforest habitats are cause for concern.

Praomys mutoni RIVERINE SOFT-FURRED MOUSE (MASAKO SOFT-FURRED MOUSE, RIVERINE PRAOMYS)

Fr. Souris sylvestre de la rivière (Souris à poil doux de Masako); Ger. Muton-Weichhaarmaus

Praomys mutoni Van der Straeten and Dudu, 1990. In: Vertebrates in the Tropics (eds G. Peters & R. Hutterer). Museum Alexander Koenig, Bonn, p. 75. Batiabongena, Masako Forest Reserve, DR Congo.

Taxonomy Species-group: *jacksoni* (Van der Straeten and Dieterlen 1987). Synonyms: none. Chromosome number: not known.

Description Small dark brown mouse. Dorsal pelage soft sepia-brown; dorsal hairs 9–10 mm. Ventral pelage whitish-grey; hairs grey at base, white on terminal end; more greyish in ♀♀ than in ♂♂. Most ♂♂ have a white patch or stripe in front of the penis. Tail very long (ca. 120–140% HB), unicoloured, rather dark, with a few short hairs between the scales. Skull: supraorbital ridges well developed and clearly bending outwards (not straight as in other species of the *jacksoni* species-group); posterior limit of anterior palatal foramina at second root of M^1 ; t_3 of M^1 well developed. Palatal ridges $2 + 5 = 7$. Nipples $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

P. jacksoni. Pelage colour paler; supraorbital ridges straight; widespread in Rainforest BZ of central Africa.

Distribution Endemic to Africa. Rainforest BZ (East Central Region). Only known from the type locality (Masako F. R., DR Congo; $00^\circ 36' N$, $25^\circ 13' E$). Probably widespread in suitable habitats north of the Congo R.

Habitat Very wet areas along rivers and rivulets within secondary forest and in old farmlands, where syntopic with *P. jacksoni*.

Abundance Rare and localized. In preferred wet habitats, comprised 2.1% of trapped small mammals; overall in Masako F. R. comprised 0.85% of rodents ($n = 4000$ rodents).

Praomys mutoni

Remarks Pregnant ♀♀ recorded at beginning (Dec) and end (Feb) of dry season. Embryo number: 2–3 (Dudu 1991).

Conservation IUCN Category: Data Deficient.

Erik Van der Straeten

Praomys obscurus OBSCURE SOFT-FURRED MOUSE (GOTEL MOUNTAIN PRAOMYS)

Fr. Souris sylvestre obscure; Ger. Dunkel Weichhaarmaus

Praomys obscurus Hutterer and Dieterlen, 1992. Bonn. Zool. Beitr. 43: 402. Gangirwal, Gotel Mts, Mambilla Plateau, SE Nigeria. 2300 m.

Taxonomy Species-group: *tullbergi*. Originally described as a subspecies of *P. hartwigi* (Hutterer *et al.* 1992). The status of *obscurus* is uncertain: it may be a subspecies of *P. hartwigi* or a valid species. Here (following Musser & Carleton 2005), *P. obscurus* is given specific rank. The two species, *P. hartwigi* and *P. obscurus*, have very restricted geographic ranges in separate montane forests, separated from each other by about 100 km of savanna. Synonyms: none. Chromosome number: not known.

Description Medium-sized dark rainforest mouse, but comparatively large for a species in this genus. Pelage soft and long (13–15 mm on back). Dorsal pelage dark brown to greyish-black, especially on mid-dorsal line, without any russet tinge as in *P. hartwigi*; hairs dark grey with subterminal band of pale brown or beige, and black at tip. Dorsal pelage slate-grey in young animals. Flanks slightly paler. Ventral pelage whitish-grey; hairs dark grey at base, off-white

at tip. Colour of flanks and ventral pelage delineated by thin line of pale reddish-brown. Head similar in colour to dorsal pelage. Ears large, darkly pigmented with sparse short dark hairs. Forelimbs pale, with sparse short whitish hairs; five digits, Digit 1 reduced to tubercle with very small claw. Hindfeet pale as forefeet; five digits each with claw. Tail very long (ca. 140% of HB), ringed with scales, appears more or less naked but covered with very small dark bristles. Palatal ridges: 2 + 7 = 9. Skull narrow and long, similar to that of *P. hartwigi* but on average shorter. Upper tooththrow short, M¹ short and narrow, molar crown pattern simplified as compared to *P. hartwigi*. Palatal ridges: 2 + 7 = 9. Nipples: 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species

P. hartwigi. Overall similar, but dorsal pelage less dark, mostly reddish-brown; on average heavier (mean WT: 57.2 g); skull (mean GLS: 32.6 mm) on average larger; upper tooththrow (mean M¹–M³: 5.6 mm) longer; occurs further south on the Bamenda Plateau, not in sympatry with *P. obscurus*.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Known only from two localities (Mt Gangirwal and Chappal Waddi) in the Gotel Mts of Nigeria (Hutterer *et al.* 1992).

Habitat Relict montane forest at 1900–2300 m on the slopes of the Gotel Mts, a plateau of about 21 km² (Chapman *et al.* 2004). Of a total of 38 specimens, 14 were collected in fern-grassland, 11 in forest, eight along streams in forest, three in gallery forest and two in forest swamp (Hutterer *et al.* 1992).

Abundance May be locally common in the Gotel Mts, but in an extremely restricted habitat.

Remarks Terrestrial and nocturnal. Females probably start to reproduce at a minimum weight of 40 g. In the Gotel Mts in 1988, four of 11 adult ♀♀ were reproductively active in the second half of Mar: one was lactating and three were pregnant. Embryo number: 3 (n = 1), 4 (n = 2). Maturation of ♂♂ at ca. 30–35.

Praomys obscurus

Conservation IUCN Category: Endangered.

Praomys petteri PETTER'S SOFT-FURRED MOUSE (PETTER'S PRAOMYS)

Fr. Souris sylvestre de Petter; Ger. Petters Weichhaarmaus

Praomys petteri Van der Straeten, Lecompte and Denys, 2003. Bonn. Zool. Beitr. 50: 333. Boukoko, Central African Republic.

Taxonomy Species-group: *tullbergi*, and a sibling species of *P. rostratus*. The species was first documented as a *Praomys* with 2n = 42 (Matthey 1965), but without a formal name, and has subsequently been referred to as 'morio' (when considered to be the same as *P. morio* from Cameroon [Matthey 1965, Petter 1975b]) or *P. lukolelae* (Petter 1975b). Phylogenetic studies show that populations in Cameroon, Gabon and Congo are not *P. morio* or *P. lukolelae*, and they are now allocated to *P. petteri* (Van der Straeten *et al.* 2003). Synonyms: none. Chromosome number: 2n = 42, aFN = 62 (Matthey 1965).

Description Small to medium-sized brown forest mouse, although one of the larger species in the genus and similar in colour to *P. rostratus*. Pelage dense and soft; hairs ca. 10 mm on mid-back. Dorsal pelage dark brown, sometimes very dark. Ventral pelage whitish-grey. Short white hairs along edge of the ears. Feet with white hairs. Tail very long (115–125% of HB), unicoloured dark brown, with irregular pale spots; a few short hairs between the scales. Skull: supraorbital ridges small or absent; posterior limit of anterior palatal

foramina at anterior edge of M¹; t3 of M¹ absent or difficult to detect. Palatal ridges 2 + 7 = 9. Nipples 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species

P. tullbergi. HF smaller; GLS on average smaller; similar pelage colour; chromosome number: 2n = 34; mainly West Africa.

P. rostratus. Similar colour; chromosome number: 2n = 34 (as in *P. tullbergi*); Senegal to Ghana.

P. jacksoni. Similar colour; can only be distinguished by skull characters; chromosome number: 2n = 42; widespread in central Africa.

Distribution Endemic to Africa. Rainforest BZ (West Central Region, Gabon Subregion). Recorded from S Cameroon, SW Congo and S Central African Republic.

Habitat Secondary forest, savanna developed after deforestation, and dry thickets. Sometimes in the neighbourhood of small villages, and occasionally within villages (Granjon, 1991). Specimens of *P. petteri* frequently occur sympatrically with *P. tullbergi* and *P. jacksoni*.

Abundance In Congo (Granjon 1991) and Cameroon (E. Van der Straeten unpubl.), this species seems to be more abundant than the syntopic *P. cf. tullbergi*.

Remarks Mainly insectivorous. Diet (as indicated by stomach contents) is mainly insects (>75% by volume) as well as grains and fruit, especially in the dry season (Genest-Villard 1980). One of the eight ♀♀ trapped in Sep was pregnant. Embryo number: 4 (n = 1; Congo; Granjon 1991).

Conservation IUCN Category: Least Concern.

Praomys rostratus WEST AFRICAN SOFT-FURRED MOUSE (WEST AFRICAN PRAOMYS)

Fr. Souris sylvestre d'Afrique de l'Ouest; Ger. Wald-Weichhaarmaus

Praomys rostratus (Miller, 1900). Proc. Washington Acad. Sci., 2: 637. Mount Coffee, Liberia.

Taxonomy Originally described as *Mus tullbergi rostratus*. Species-group: *tullbergi*. Subsequently *Praomys rostratus* was described as a distinct species (separate from *P. tullbergi* because of its larger mean size) by Van der Straeten & Verheyen (1981). In 1958, Heim de Balsac & Lamotte (1958) recorded two species of *Praomys* at Mt Nimba: *P. tullbergi* (incorrectly referred to as *P. morio*) and *P. rostratus* (incorrectly referred to as *P. jacksoni*). Synonyms: none. Chromosome number: 2n = 34 (as in *P. tullbergi*; E. Van der Straeten unpubl.).

Description Small brown forest mouse, similar in colour to *P. tullbergi*. Pelage dense and soft, ca. 10 mm on mid-back. Dorsal pelage reddish-brown to yellowish-brown in older animals; dark brown in younger ones. Ventral pelage nearly white in adult specimens; ventral hairs grey at base, white on terminal two-thirds. Hands and feet white. Some ♂♂ have white patch or stripe just in front of penis. Tail very long (ca. 115–125% of HB), dark brown, with a few short hairs between the scales; unicoloured with irregular pale spots. Skull: supraorbital ridges small or absent, originating half-way along frontal bone; posterior limit of anterior palatal foramina at anterior edge of M¹; t3 of M¹ absent or difficult to detect. Palatal ridges 2 + 7 = 9. Nipples 1 + 2 = 6.

Geographic Variation None recorded.

Similar Species

P. tullbergi. Skull and external measurements on average smaller; cannot be distinguished by pelage colour.

Distribution Endemic to Africa. Rainforest BZ (Western Region) and Northern Rainforest–Savanna Mosaic. Recorded from Senegal (Basse Casamance) to Ghana; all records west of the Dahomey Gap.

Habitat Rainforest and forest relicts, dry thickets and cultivated land (Lim & Van Coeverden de Groot 1997, Van der Straeten & Verheyen 1981). Often syntopic with *P. tullbergi*.

Abundance At Adiopodoumé (Côte d'Ivoire), *P. rostratus* was more abundant (70%) than *P. tullbergi* (30%).

Remarks Terrestrial, but also found in trees at heights of 1 m and 2.5 m in Côte d'Ivoire. Reproductively active in Feb (no samples in other months): ♂♂ had scrotal testes, and all ♀♀ (n = 6) were pregnant. Embryo number: 2–4 (Lim & Van Coeverden de Groot 1997).

Praomys rostratus

Conservation IUCN Category: Least Concern.

Praomys tullbergi TULLBERG'S SOFT-FURRED MOUSE (TULLBERG'S PRAOMYS)

Fr. Souris sylvestre de Tullberg; Ger. Tullbergs Weichhaarmaus

Praomys tullbergi (Thomas, 1894). Ann. Mag. Nat. Hist., ser. 6, 13: 205. Ankober River, Wasa, Ashanti, Ghana.

Taxonomy Originally described in the genus *Mus*. Species-group: *tullbergi*. Synonyms: *burtoni*. Subspecies: none. Chromosome number: $2n = 34$ (Central African Republic; Petter 1975b); $2n = 34$ (Côte d'Ivoire; Matthey 1958); $2n = 34$, $FN = 32$, all acrocentric autosomes (Senegal; Granjon *et al.* 1992).

Description Small forest mouse. Pelage soft. Dorsal pelage reddish-brown; hairs grey at base, greyish-brown to rufous-brown tips. Ventral pelage greyish; hairs grey at base, white at tip. Chin, throat and chest whitish. Head narrow and pointed, moderate to large eyes, large fleshy ears. Palatal ridges $2 + 7 = 9$. Fore- and hindfeet white. Tail very long (ca. 140% of head and body), with short sparse bristles. Considerable variation in pelage colour: dark grey in juveniles, greyish-brown in young adults and rufous-brown to reddish-brown in old individuals. Males often slightly larger than ♀♀. Skull: supraorbital ridges small or absent, originating half-way along frontal bone; posterior limit of anterior palatal foramina at anterior edge of M^1 ; $t3$ of M^1 absent or difficult to detect. Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

P. daltoni. Ventral hairs pure white; nipples $3 + 2 = 10$; savanna habitats only.

P. rostratus. On average larger; sympatric west of Dahomey Gap.

P. jacksoni. On average larger; palatal ridges $2 + 5 = 7$; mostly allopatric but may be sympatric in parts of Cameroon.

Hylomyscus stella. Primarily arboreal; hindfeet smaller and usually shorter; tail on average relatively longer; nipples $2 + 2 = 8$.

Distribution Endemic to Africa. Rainforest BZ (Western Region and West Central Region) and Northern Rainforest–Savanna Mosaic. Recorded from Gambia and SW Senegal to Ghana, and from W Nigeria to Cameroon, Gabon and Central African Republic. Isolated populations in Togo and Benin (Dahomey Gap), and in forest relicts in Northern Rainforest–Savanna Mosaic. Lower altitudes of Mt Cameroon (up to ca. 600 m); replaced by *P. morio* at higher altitudes on the mountain. Eastern limit of geographic range uncertain.

Habitat Primary and secondary rainforest, where soil is covered by leaf litter and small well-spaced forest herbs and shrubs. Also recorded in cultivated areas close to the forest, abandoned farmlands, cocoa plantations, oil palm plantations, forest clearings and along logging tracks in the Rainforest BZ. Occurs in forest relicts in savanna habitats where structure and characteristics resemble rainforest (Happold 1975b; Decher 1997). Not recorded in savanna grasslands.

Abundance Often the most abundant species of small terrestrial rodent in rainforest habitats of West Africa, e.g. comprised 30–57% of all terrestrial rodents in Sierra Leone (Cross 1977), 37% (Cole 1975) and 57% (Jeffrey 1977) in Ghana, and 75–86% in Nigeria

Praomys tullbergi

(Happold 1975b, 1977). In some areas (e.g. Côte d'Ivoire), they were the second most abundant small rodent (32%) after *Hylomyscus alleni* (as *H. simus*) (34%) (Adam 1977). In Central African Republic, the percentage abundance varied by habitat: 15% in *Gilbertiodendron* forest, 20% in natural mixed species forest and 40% in more open habitats along forest tracks (Ray 1998). Density ranges from 0.4 to 2.7 individuals/ha in Gabon (Duplantier 1989). During a 3-year period at a single study site in Gambari Forest, Nigeria, population density varied from 9.5/ha to 27.9/ha depending on year and season (Happold 1977, 1978, 1979). Mean biomass ranged from 47 g/ha (range 15–86 g/ha) in Gabon (Duplantier 1989) to 514 g/ha (range 185–920 g/ha) in Nigeria (Happold 1977).

Adaptations Terrestrial and nocturnal; occasionally scansorial. Lives in holes in fallen logs, in crevices under living trees and buttress roots, old termite mounds and in cracks in the soil. Not known to dig burrows. Constructs nests of dead forest leaves, laid flat to form a saucer-shaped depression. Radio-collared individuals exhibited several peaks of activity during the night; ♂♂ showed greater activity than ♀♀. Average distance travelled each night was 227 m by males and 169 m by females (Duplantier 1982).

Foraging and Food Omnivorous, and probably opportunistic. In Ghana, diet was mainly vegetable material (fruits, shoots and seeds) but also some insects (ants, termites, grasshoppers and beetles) (Cole 1975). In Gabon, mostly fruit pulp and seeds with some insects (Duplantier 1982), and in Central African Republic, insects (mostly ants and termites, 70–75% by volume), many species of seeds and

fruits (ca. 25%) and a few other invertebrates (6–8%) (Genest-Villard 1980).

Social and Reproductive Behaviour Home-ranges of ♂♂ and ♀♀ are similar in area (♂♂: 0.23 [0.11–0.39] ha, $n = 19$; ♀♀: 0.22 [0.13–0.30] ha, $n = 14$), with extensive overlap between individuals (Happold 1977). Social organization is communal, and individuals show a high frequency of amicable behaviour. Individuals of different sexes nest together, and young often nest with the mother after weaning.

Reproduction and Population Structure Time of reproduction is similar throughout the geographic range of the species. In Nigeria, for example, reproduction occurs in all months of the year, with two peaks of reproductive activity, one at the end of the dry season and during the early wet season (Feb–Apr), and the second after the little dry season (Oct, Nov) (Happold 1977, 1987). Reproduction is rapid because of the following characters: oestrus cycle 6–7 days; gestation 23–24 days, young weaned at Day 24–25, first conception at 84 (62–115) days, and minimum time between consecutive litters (in captivity) 23–30 days (Happold 1978). Embryo number varies slightly by locality: Sierra Leone 3.45 (2–4) (Cross 1977); Ghana 3.7 (2–6), mode 3 or 4 (Jeffrey 1975, 1977); and Nigeria 3.6 (2–6), mode 3 or 4 (Happold 1978). Litter-size at birth for 103 parturitions in captivity was 3 (1–6; Happold 1978).

In Nigeria (Happold 1977), population structure remains fairly constant throughout the year as a result of more-or-less continuous reproduction and a steady rate of mortality and/or emigration. All five age-weight classes (<1 month, 1–2 months, 3–4 months, 4–6 months, 6–18 months) present in most months; two youngest age-

classes absent when reproductive rate declines. Commonest age-classes: 3–4 months and 4–6 months. Survival rate of young entering the population is 0.52 after one month, 0.29 after three months, 0.20 after five months and 0.11 after 11 months; maximum known age in the wild is 18 months; 83% of population replaced every six months.

Predators, Parasites and Diseases In Central African Republic, comprised nearly 10% of small mammal remains in scats of various carnivores (total $n = 732$), and 29% of rodents less than 100 g ($n = 251$) (Ray 1998).

Conservation IUCN Category: Least Concern.

Praomys verschureni VERSCHUREN'S SOFT-FURRED MOUSE (VERSCHUREN'S PRAOMYS)

Fr. Souris sylvestre de Verschuren; Ger. Verschurens Weichhaarmaus

Praomys verschureni (Verheyen and Van der Straeten, 1977). Rev. Zool. Afr. 91: 739. Mamiki, DR Congo.

Taxonomy Originally described in the genus *Malacomys*, on the basis of one specimen. Four additional specimens were obtained between 1977 and 1993 (Robbins & Van der Straeten 1982, Dieterlen & Van der Straeten 1984), and a further 31 were collected in Irangi, DR Congo (F. Dieterlen unpubl.). Although described in the genus *Malacomys*, *verschureni* is close to *Praomys* and is considered here as a species of *Praomys* (Van der Straeten & Kerbis Peterhans 1999, Musser & Carleton 2005). Species-group: *lukolelae*. This taxon, together with *P. lukolelae*, may represent a separate genus (E. Van der Straeten unpubl.). Synonyms: none. Chromosome number: $2n = 58$, FN = 58 or 60 (Robbins & Van der Straeten 1982).

Description Medium-sized with very long tail and long hindfeet, showing characters of both *Praomys* and *Malacomys* (see also *P. lukolelae*). Pelage soft and long (ca. 12 mm), texture sleek as in *Praomys*. Dorsal pelage dark grey washed with some brown; hairs dark grey at base with white at extreme base, brown at tip. In older animals, pelage becomes brownish, similar to that of *P. jacksoni*. Flanks brownish, especially anteriorly. Ventral pelage grey; hairs dark grey at base, white at tip. Colour of dorsal and ventral pelage clearly delineated. Ears rounded, inner and outer surfaces sparsely covered with short brownish hairs.

Vibrissae long (30–40 mm). Palatal ridges $2 + 6 = 8$. Upper sides of fore- and hindfeet whitish (unpigmented) with very short white hairs. Hindfeet comparatively long; soles with six plantar pads, claws short. Tail very long (ca. 120% of HB), dark (sometimes partly unpigmented), mostly naked, but sparsely covered with short whitish bristles. Skull: not very elongated, as in *Praomys* (cf. *Malacomys*); posterior limit of anterior palatal foramina anterior to M¹ (as in *Malacomys* spp.); sides of frontal bones rounded and without supraorbital ridges. Upper incisors between ortho- and opisthodont. t3 of M² usually present (rarely present in *Malacomys* spp.). t9 on M¹ and M² absent (same as in *Malacomys* spp.). Mandible relatively large (as in *Malacomys* spp.). Nipples: $1 + 2 = 6$.

Geographic Variation None recorded.

Similar Species

Praomys (other spp. groups) Hindfeet on average shorter (means 22–25 mm).

Malacomys longipes. Hindfeet longer (39.4 [36–41] mm).

Distribution Endemic to Africa. Rainforest BZ (East Central Region). Known from four localities: Irangi, E DR Congo; Mamiki

near Beni, NE DR Congo; Epulu (Ituri), NE DR Congo (J. Kerbis unpubl.); and Tandala near Gemena, N DR Congo. All localities are east and north of the Congo R. Distribution is probably limited to the west and south by the Congo R., and to the east and north by the northern edge of the rainforest.

Habitat Lowland rainforest and sub-montane forest. The holotype was captured close to water in *Cynometra* forest. At Irangi (850 m), found in hilly rainforest where typical trees were *Pygnanthus angolensis*, *Annonidium manni*, *Julbernardia seretii*, *Gilbertiodendron dewevrei*, *Staudtia stipitata* and *Uapaca* sp. In sub-montane forest (1000–1800 m), preferred habitat contained *Strombosia scheffleri*, *Ocotea usambarensis*, *Bridelia brideliiifolia*, *Polyscias kivuensis*, *Carapa grandiflora*, *Lebrunia bushaie* and *Musanga leo-errerae*.

Abundance Rather varied. Extremely rare in lowland rainforest, comprising <0.01% of captures, and 0.6% in pure primary forest. In contrast, comprised 12.3% and was the fourth commonest species of all small mammals (17 spp.) in sub-montane forest at 1250–1650 m (F. Dieterlen unpubl.).

Remarks Omnivorous. Stomach contents (n = 11) were either only invertebrate remains – mainly arthropods and their larvae discernible by pieces of chitin, fatty tissues and muscle fibres (n = 6) – or were invertebrate remains with 50% plant material, which was mostly whitish homogeneous material (probably from nuts, kernels or tubers) without any typical plant fibres or green matter (n = 5) (F. Dieterlen unpubl.). At Irangi, E DR Congo, ♀♀ in reproductive condition (pregnant or lactating) were caught between Sep and Apr (n = 13 adults), months when most other small mammals were also reproducing (limited sampling in other months). Embryo number: 3 (n = 1). Five of the seven lactating ♀♀ were obtained in Apr, and none of the lactating ♀♀ was pregnant. Sex ratio of captures unusually biased (35 : 65%, n = 34) towards ♀♀.

Conservation IUCN Category: Data Deficient.

GENUS *Rattus*

Rats

Rattus Fischer, 1803. Natl Mus. Nat. Paris, 2: 128. Type species: *Mus decumanus* Pallas, 1778 (= *Mus norvegicus* Berkenhout, 1769).

The genus *Rattus* is one of the most widespread of rodent genera in the world, occurring on all continents of the world except Antarctica, and also on many islands where it has been introduced (mostly inadvertently) by humans (see also Rosevear 1969). The number of species is uncertain, but is in the order of 56 (Musser & Carleton 1993) to 66 species (Musser & Carleton 2005); of these only two species occur in Africa, both of them introduced by humans in recent times (see Rodentia profile). The following notes are mostly restricted to the two African species.

The genus is characterized by large body size for a murid (mean HB length in Africa at least 165 mm), typically ‘rat-like’ shape,

coarse pelage and long naked tail with small scales. The dorsal pelage and flanks are dull brownish or blackish, and ventral pelage is grey, yellow or white. There are no stripes or colour patterns on the pelage. The skull (Figure 83) is relatively narrow, with mean length of at least 39 mm, slender zygomatic arches, strong supraorbital ridges, moderate-sized auditory bullae and relatively small cheekteeth. Incisors are wide, smooth, without notch on posterior surface (cf. *Mus*), ungrooved and opisthodont. M¹ has five roots.

The genus is not indigenous to Africa, and is assumed to have entered Africa by various means of human transport, notably by ships arriving at African ports. The two species in Africa have restricted

Figure 83. Skull and mandible of *Rattus rattus* (HC 463).

Rattus norvegicus BROWN RAT (NORWAY RAT)

Fr. Surmulot (Rat d'égouts); Ger. Wanderratte

D. C. D. Happold

Rattus norvegicus (Berkenhout, 1769). Outlines of the Natural History of Great Britain and Ireland, 1:5. Great Britain (no precise locality stated).

Taxonomy Originally described in the genus *Mus*. Original distribution assumed to be SE Siberia, N China and parts of Japan but now an introduced species in many parts of the world. The Brown Rat is the wild ancestor of the laboratory white rat extensively used in medical and pharmacological research. Synonyms: many, mostly non-African (see Musser & Carleton 2005 for details). Chromosome number: $2n = 42$.

Description Large rat with long coarse shaggy blackish-brown pelage, and tail shorter than head and body. Dorsal pelage dark brown or blackish-brown, often flecked with rufous; hairs grey at base, blackish-brown at tip. Flanks paler, grey-brown. Ventral pelage grey; hairs grey sometimes with white tips. Ears relatively short (ca. 44% of GLS) with many small darkish hairs. Muzzle blunt. Fore- and hindlimbs similar in colour to ventral pelage; fore- and hindfeet with sparse white hairs above, naked and fleshy below. Tail thick at base, relatively long (ca. 90% of HB), mostly naked with scattered short bristles; brownish above, whitish below. Skull: supraorbital and temporal ridges well-defined; curve strongly outwards from interorbital constriction and then run parallel along edge of braincase. Nipples: usually $3 + 3 = 12$.

Geographic Variation None recorded in Africa.

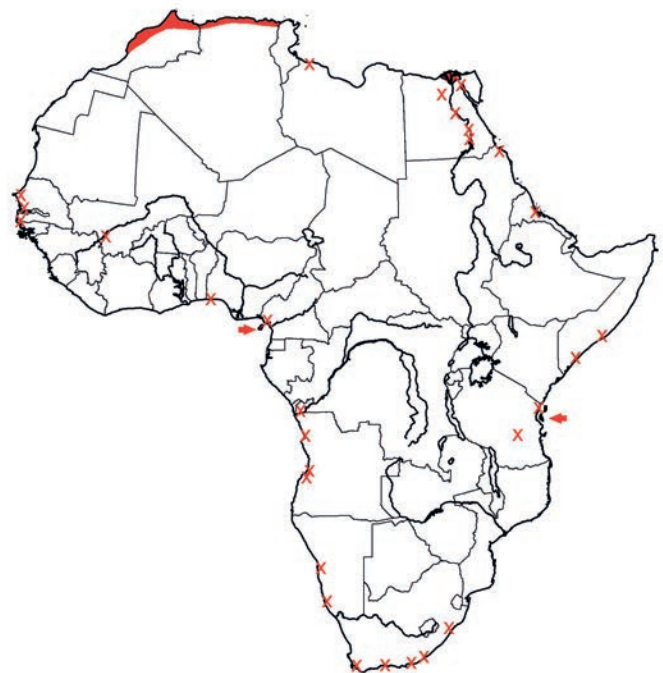

Similar Species

R. rattus. On average smaller; tail longer than HB; HF less than ca.

geographic distribution on the continent, *R. norvegicus* more so than *R. rattus*. Neither species has invaded natural ecosystems to any significant extent: *R. norvegicus* is restricted to coastal ports and *R. rattus* has invaded the interior but is mostly confined to human habitations and some farmlands. Importantly, both species are pests of stored food (as are some indigenous species, notably *Mastomys* spp.) and are reservoir hosts of some human diseases (see species profiles).

The number of species in the genus was larger in the past than now. After the definition of the genus by Fischer, most 'rats' were placed in the genus *Rattus*. In 1915, Thomas reduced the number of species, by placing various 'Rattus-like' species in subgenera, which, in 1926, were raised to generic rank. These generic ranks are maintained to the present time (although Ellerman [1940] lumped them all in *Rattus* again) and include, *inter alia*, the African genera *Aethomys*, *Stochomys*, *Praomys*, *Hylomyscus* and *Mastomys* (see Misonne 1969a, De Graaff 1981). A full discussion of the genus is given in Musser & Carleton (2005).

The two African species are distinguished by body size and shape, length of hindfoot, relative size of ears, and shape of the supraorbital ridges.

Rattus norvegicus

35 mm; ears naked, ca. 59% of GLS; more widespread in Africa. *Nesokia indica*. Smaller with much shorter tail; skull robust with laminate molars; Egypt only.

Distribution Introduced to Africa by ships to seaports on the coast, and recorded only at major ports, and at some localities on the Nile R. in Egypt. Unlike other introduced small rodents in Africa (e.g. *R. rattus* and *Mus musculus*), has not normally dispersed away from the coastal towns and cities of Africa south of the Sahara. Unknown in Morocco, except in coastal ports, prior to 1910; since 1910 has spread throughout N Morocco (Aulagnier & Thévenot 1986). Recorded from Bamako (on the Niger R. in Mali) (Meinig 2000). Outside Africa, occurs in all continents (except Antarctica) and on many islands.

Habitat Houses and human habitations; drains, rubbish tips and sewers. Requires permanent water, and may live in swampy ground and in drainage banks. Commensal with humans.

Abundance Little information for Africa. In suitable habitats (outside Africa) may be very numerous because of high reproductive rate (see below). In Lagos, Nigeria, during 1931–34, Brown Rats comprised only 5% of the population of Black Rats and Brown Rats.

Adaptations On a worldwide basis, Brown Rats are very successful because of commensalism, high reproductive rate, omnivorous diet and fearless nature. Well adapted to colonize cold climates – a character that partly explains why they have not been successful colonists in Africa. Nocturnal and terrestrial; scansorial (but less so than Black Rats). They are bold and aggressive, bite if handled; and tend to be more wary of humans than Black Rats. They can chew wood and other materials with their large incisor teeth in order to gain access to new habitats. Individuals living on irrigation banks (e.g. in Egypt) dig shallow burrows and are good swimmers. Brown Rats have not been studied extensively in Africa because of their limited distribution and importance, although they (and the diseases they transit) have been well studied in temperate countries (see, e.g. Macdonald *et al.* 1999).

Foraging and Food Omnivorous, feeding on almost anything that is edible, including human food and stored crops.

Social and Reproductive Behaviour Gregarious. Brown Rats often form multimale, multifemale groups, which may defend a clan territory, especially where resources are abundant. Social organization within a group determines many aspects of behaviour and survival. Larger, dominant individuals (i.e. those with high social status) are the most successful members of a group. Social dominance confers great advantages: access to food, higher reproductive success and reduced susceptibility to adverse conditions. Social pressures determine which individuals remain and which leave the group. Young subordinate ♂♂ are usually forced to emigrate to less favourable habitats. Reproductive behaviour is complex: a dominant ♂ does not

necessarily have the highest reproductive success because ♀♀ mate with several ♂♂ while in oestrus, and ♀♀ exercise mate choice. Olfaction is a very well-developed sense, and the various odours produced by individuals convey important signals to other members of the group (Macdonald *et al.* 1999, and references therein).

Reproduction and Population Structure Little information is available on reproduction in Africa. In Lagos, pregnancies occurred throughout year, pregnancy rate varying from 7 to 8% of ♀♀ in the dry season (Dec–Apr) to 8–15% in the wet season (May–Nov) (Buxton 1936). Brown Rats breed prolifically, and ♀♀ may produce several litters in a breeding season; hence populations can increase rapidly when conditions are optimal. Typical reproductive data: gestation: 21–24 days; litter-size 6–12; young born naked and blind; eyes open Day 6, weaned at Day 21; maturity in ♀♀ at about 11 weeks (Corbet & Southern 1977). Because of large litter-size and prolonged breeding season, populations usually consist mostly of young and subadult animals.

Predators, Parasites and Diseases Like Black Rats, Brown Rats are pests because of their unsanitary habits and because they harbour parasites that transmit diseases to humans (including plague). Many species of fleas and mites have been recorded from wild-living rats (De Graaff 1981). *Xenopsylla cheopis* was the commonest species of flea (of four species) found on Brown Rats in Egypt (Hoogstraal & Traub 1965b).

Conservation IUCN Category: Least Concern.

Control of Brown Rats is essential to reduce the damage they cause to buildings and food supplies, and to minimize the spread of disease.

Rattus rattus BLACK RAT

Fr. Rat noir; Ger. Hausratte

Rattus rattus (Linnaeus, 1758). Syst. Nat., 10th edn., 1: 61. Uppsala, Sweden.

Taxonomy Originally described in the genus *Mus*. The widespread distribution and large variation in colour has resulted in many taxonomic names being applied to this species. Most of these names

are now considered to be synonyms, although some are used to describe the clearly recognizable colour forms. Musser & Carleton (2005) list 84 synonyms worldwide. In Africa, there are three colour

forms (see Geographic Variation), which, in the past, have sometimes (incorrectly) been referred to as subspecies. More than one form may occur at a single locality, and sometimes a single litter may contain more than one colour form (Rosevear 1969). Nevertheless, a specified locality normally contains only one colour form. Synonyms: see details in Musser & Carleton (2005). Subspecies: none. Chromosome number: $2n = 38$, $FN = 58$ (Niger; Dobigny *et al.* 2002b). The same chromosome number has been recorded in Black Rats from Benin (Capanna *et al.* 1997), Senegal, South Africa and Djibouti (Capanna & Civitelli 1971).

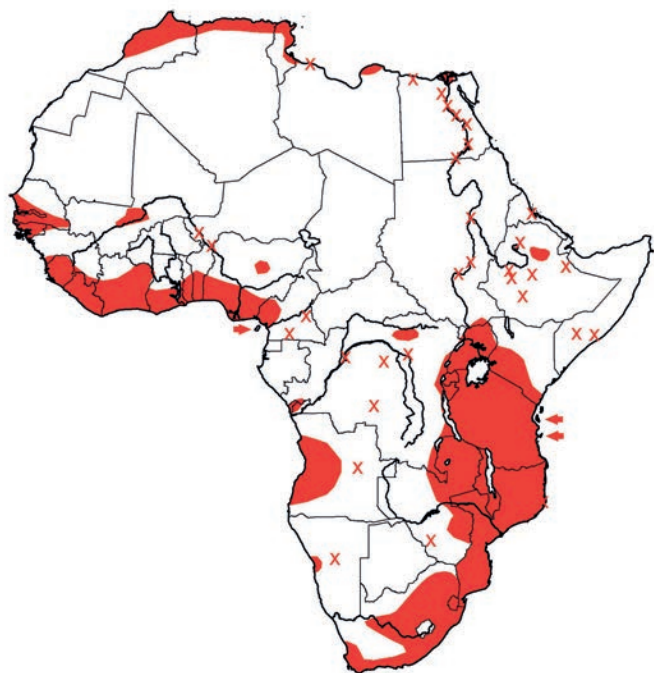

Description Large rat, with blackish-brown dorsal pelage and long scaly naked tail. Pelage coarse and dense, sleek, lying close to body. Dorsal pelage dark brown or blackish-brown, usually darker along mid-dorsal line; hairs medium grey at base, with pale brown, dark brown or black tip. Many long dark guard hairs scattered throughout dorsal pelage. Ventral pelage varied, either pale to dark brown, or lemon-yellow, or white. Individuals with brown ventral pelage may have white patches on chest and throat. Ears naked; ca. 59% of GLS. Fore- and hindlimbs dark greyish-brown. Well-developed digits, upper surfaces with greyish-brown hairs. Forefoot with four digits; hindfoot with five digits. Tail very long (ca. 120% of HB), thin, with scales arranged in rings along length of tail and many short dark bristles. Skull: supraorbital and temporal ridges well defined; curve strongly outwards from interorbital and then curve inwards along edge of braincase. Nipples: $3 + 2 = 10$, $3 + 3 = 12$.

Geographic Variation Three colour forms are known in Africa:

frugivorous: ventral pelage white or lemon-yellow; dorsal pelage pale brown or reddish-brown.

alexandrinus: ventral pelage grey-brown; dorsal pelage grey-brown or medium-brown.

rattus: ventral pelage pale brown or dark brown; dorsal pelage blackish or dark brown.

Rattus rattus

Similar Species

R. norvegicus. On average larger; ears with short hairs, ca. 44% of GLS; HF > 35 mm; tail shorter than HB; restricted to coastal districts.

Mastomys spp. Smaller; pelage soft; ♀♀ with continuous rows of nipples (up to a total of 24 nipples).

Distribution Introduced to sub-Saharan Africa by Arab and European ships, and subsequent dispersal within Africa mainly by river, rail and road transport. Recorded in many biotic zones (see map). Occurs mainly in moister habitats, although some populations live in arid habitats where there is permanent water (e.g. upper reaches of the Niger R. and lower reaches of the Nile R.). More widespread in savanna habitats of eastern Africa than in western Africa. Fairly widespread in temperate habitats of North Africa and southern Africa (but see Habitats). Outside Africa, occurs in all continents (except Antarctica) and on many islands.

The dispersal of Black Rats is well documented in parts of Africa. In Senegal, for example, Black Rats were present in towns along the Senegal R. during nineteenth century when the river was the only trade route to Mali. They colonized the centre of Senegal from Dakar eastwards during the building of the railway to Mali and hence are now present in Bamako (Duplantier *et al.* 1991). At the end of the twentieth century, they invaded SE Senegal along the tarmac road through the Niokolo-Koba N. P. (Bâ 2002). In East Africa, Black Rats may have been present on the coast for many centuries, arriving in sailing ships and dhows, and then travelling along caravan routes to the interior (Dieterlen 1979b). They were recorded from Mombasa and Dar-es-Salaam in 1895; the building of railway lines and roads enabled Black Rats to colonize the interior of East Africa: they were first recorded in Tabora in 1895, Kisumu in 1901 and Kampala in 1911 (Misonne 1963, Delany & Happold 1979, Dieterlen 1979b). Some individuals probably crossed L. Victoria by boat, since they were recorded in W Uganda (at Katwe) in 1906–09. Later, during the late 1930s, they spread throughout most of W Uganda and in the early 1950s reached E DR Congo (Misonne 1963). In some parts of Tanzania, dispersal from Dar-es-Salaam was slower, and Black Rats did not reach Serengeti (at Seronera) until 1976 (Senzota 1982). The pattern of dispersal has been similar in all parts of Africa: arrival at a port and subsequent transportation to locations where there are human habitations. Undoubtedly, the distribution of Black Rats is still expanding, and their numbers are increasing. Of the three introduced species of small rodents in Africa, *R. rattus* has colonized the continent to a much greater extent than *Mus musculus* and *R. norvegicus*.

Habitat Houses, food stores and warehouses in cities, towns and villages; abandoned farmland and close to streams in urban areas. Commensal with humans. Rarely found in natural habitats.

Abundance In preferred habitats, Black Rats may be very common, although population numbers may vary greatly between years and between seasons.

Adaptations Nocturnal and diurnal, terrestrial and scansorial. Black Rats are agile climbers, and frequently live in roofs of houses, under wooden floors, and high up in multi-storey buildings. Their boldness, lack of fear of humans and ability to eat many sorts of foods (see below) allow them to live in close association with humans

where they may cause damage to buildings and food stores. These characters, coupled with their high reproductive rate, result in rapid increases in population numbers when conditions are suitable, and increase their impact as a pest species. Although they may be rarely seen, their presence is indicated by their large faecal pellets and by stains along runways (produced by urine and secretions from skin glands).

Black Rats rarely invade natural habitats in Africa (although they may occur in abandoned farmlands close to urban settlements), hence they do not compete or displace indigenous species of rodents in natural habitats. However, because of their larger size and competitive supremacy, Black Rats have displaced *Mastomys natalensis* (and other *Mastomys* spp.) as the major rat pest in houses in Uganda and E DR Congo (Misonne 1963).

Foraging and Food Omnivorous, feeding on almost anything that is edible, including many foods stored for human consumption (e.g. wheat, maize, millet, etc.).

Social and Reproductive Behaviour Sociable and gregarious. In a wild-living population in Ghana (Ewer 1971) there was a single dominant ♂, and at times a linear male hierarchy was formed. Usually 2–3 mutually tolerant top-ranking ♀♀ were subordinate to the dominant ♂. A group territory was established around a feeding location, and was defended against non-members of the group. Both sexes chased non-members away, but non-member ♀♀ were mainly chased by the resident ♀♀. Territorial boundaries were marked by rubbing secretions from the cheeks and ventral surface onto branches and other objects. Black Rats exhibit well-documented behaviour: tooth gnashing (response to unfamiliar stimuli), piloerection and posturing with stretched legs (threat signals), vibrations of the tail (a sign of defeat or frustration) and social grooming (bonding between individuals). Black Rats are good at 'problem-solving'; once a solution has been found, it is remembered and subsequently perfected. Rats also appear to learn by imitating the behaviour of other members of the group. Lactating ♀♀ show aggression when other members approached the nest. Play is an important pastime for young animals (Ewer 1971).

Reproduction and Population Structure Very prolific. When conditions are suitable (as in human habitations where food and water are available at all times), breeding occurs throughout the year, e.g. in Uganda (Delany 1975), Zimbabwe (Smithers 1975) and Nigeria (Buxton 1936). Although reproduction within a population may be continuous, in Uganda only 37% of all females were pregnant at any one time (Delany 1975). In Lagos and Dakar, pregnancies occurred in all months, pregnancy rates varying from 11 to 13% of females in the dry season to 13–14% in the wet season in Lagos, and up to 38% in the wet season in Dakar (Buxton 1936). Continuous reproduction, large litter-size and rapid development can result in rapid increases in population numbers within a short period of time; hence populations are very responsive to changing environmental conditions. Gestation for primiparous ♀♀: ca. 21 days; for lactating ♀♀: 23–29 days (Ewer 1971). Postpartum oestrus usually within 24 hours of parturition. Mean litter-size: 6 (n = 55, mode 6 or 7)

(Uganda; Delany 1975). Typical range of litter-size: 5–10. Growth and development is rapid – fine fur all over body by Day 8, eyes open Day 10–14; solid food eaten Day 15–18, weaned Day 30; sexual maturity Day 100–120. Females may have many litters per year (often one litter/month).

Predators, Parasites and Diseases Black Rats occur primarily in urban areas, and hence the only predators are those mammalian carnivores, raptors and snakes that also occur in urban environments (e.g. domestic cats and dogs, Barn Owls, etc.). In Egypt, *Xenopsylla cheopis*, *Synosternus cleopatrae* and *Echidnophaga gallinacea* were found frequently on Black Rats; and almost any species of flea occurring in towns and gardens may parasitize these rats (Hoogstraal & Traub 1965b). Black Rats also carry many species of mites, ticks and parasitic worms (De Graaff 1981). One species of flea, *Xenopsylla cheopis*, is of particular concern to humans because it transmits a bacterium *Yersinia pestis* that causes the disease called plague or 'Black Death', which is usually fatal in humans. Black Rats also die very quickly from plague, so fleas living on them have to find another host, which in urban environments is usually a human. When Black Rats and humans are living in close association, it is difficult to break the cycle of transmission from rat to human, and human to rat. Plague was very common in Europe during the Middle Ages and caused severe epidemics that killed many thousands of humans. In more recent times (1993, 1994), Black Rats have been responsible for outbreaks of plague in some harbours and large towns in Mozambique, Tanzania, DR Congo and Zimbabwe (Gratz 1997). There is always the chance of future outbreaks wherever there are large populations of humans and Black Rats living together in unsanitary conditions. (Some species of indigenous rodents [*Mastomys* spp., *Tatera* (now *Gerbilliscus*) spp.] are also known to be reservoirs of the bacterium and so they form natural foci of the disease in Africa). Black Rats are the main reservoir of murine typhus in Africa (Gratz 1997) and of leptospirosis in Zimbabwe (Dalu & Feresu 1997).

Conservation IUCN Category: Least Concern.

Control of Black Rats is essential to reduce the damage they cause to buildings and food supplies, and to minimize the spread of disease.

D. C. D. Happold

GENUS *Rhabdomys*

Four-striped Grass Mouse

Rhabdomys Thomas, 1916. Ann. Mag. Nat. Hist., ser. 8, 18: 69. Type species: *Mus pumilio* Sparrman, 1784.

Rhabdomys pumilio.

A monotypic genus of small mice distributed throughout southern Africa and the eastern side of the continent as far north as Uganda. In East Africa, the genus is restricted to higher altitudes, but in southern Africa it is widely distributed from near sea level to 1800–2200 m. These mice live in many types of grassland, bush and woodland habitats in dry, wet, hot and cold environments. The single species is widespread and common in the southern part of its range, but less common with a very disjunct distribution in the north of its range.

The genus is characterized by the unique pattern of lateral stripes on the dorsal pelage and flanks (cf. *Lemniscomys*, *Pelomys* and *Hybomys*). The skull has ungrooved incisors, well-developed supraorbital ridges, cheekteeth with well-developed cone-like cusps, and the zygomatic plate has an almost vertical anterior face. The surface of the skull and the inner surface of the skin are often black or darkened due to deposits of melanin, as in *Lemniscomys* (see species profile for further details) (Figure 84).

Hill & Carter (1941) recognized two species in Angola on the basis of colour and size of the auditory bullae: *R. pumilio* (central and southern regions) is smaller and darker, with well-developed stripes and small auditory bullae; *R. bechuanae* (arid regions) is larger and very pale, with indistinct stripes and larger auditory bullae. Currently only one species is recognized. Variability in pelage colouration has resulted in the description of many subspecies, most of dubious validity. The phylogenetic relationship and taxonomic status of the many isolated populations in eastern Africa await investigation.

Figure 84. Skull and mandible of *Rhabdomys pumilio* (HC 2738).

Morphological characters place *Rhabdomys* in a group with *Arvicanthis*, *Lemniscomys*, *Myiomys* and *Pelomys*. Analysis of mitochondrial DNA, cytochrome *b* and rRNA sequences support such a grouping, but also show that *Rhabdomys* is in the same lineage as *Desmomys*, and separate from the lineage containing *Lemniscomys* (despite the somewhat similar pattern of longitudinal stripes on the pelage) and from the lineage containing *Arvicanthis*, *Myiomys* and *Pelomys* (Ducroz *et al.* 2001, Musser & Carleton 2005). Based on the sequence of mtDNA of cytochrome *b*, Rambau *et al.* (2003) suggest the existence of two species in southern Africa: *R. pumilio* representing the western form in arid habitats, and *R. dilectus* (= *R. dilectus* [de Winton 1897]) representing an eastern and northern form inhabiting more mesic habitats. Musser & Carleton (2005) recognize both *R. pumilio* and *R. dilectus* as valid species, giving the range of *R. pumilio* as restricted to 'xeric grasslands and savannas from W South Africa north through Namibia and C and S Botswana to SW Angola'. Thus populations from Uganda and Kenya southwards to E Zimbabwe and E South Africa are considered as *R. dilectus*. The biological information given below may, therefore, refer to either one or both species. Further study is required to ascertain the number of species in this genus.

D. C. D. Happold

Rhabdomys pumilio FOUR-STRIPED GRASS MOUSE

Fr. Rat rayé champêtre; Ger. Vierstreifengrasmaus (Striengrasmaus)

Rhabdomys pumilio (Sparrman, 1784). K. Svenska Vet.-Akad. Handl. Stockholm, p. 236. Slangrivier, Tsitsikamma Forest, east of Knysna, S Western Cape Province, South Africa.

Taxonomy Originally described in the genus *Mus*. Historically placed in either the genus *Mus* or the genus *Arvicanthis*. Meester *et al.* (1964) suggested that at most two subspecies, a darker eastern and a paler western, can be recognized in southern Africa. However, there is a complex pattern of geographic variation involved, in which more subspecies may well be distinguishable. Meester *et al.* (1986), broadly following Ellerman *et al.* (1953), provisionally listed seven subspecies in southern Africa. Many names have been associated with the species, but the status of subspecies is uncertain, and none is recognized here (but see also below). A revision of the species by Rambau *et al.* (2003) using mtDNA shows that there are two highly divergent clades within the species. One clade (named as *R. pumilio*) represents populations with $2n = 46$, which occur throughout the western more arid range of the species (Namibia, W South Africa). The second clade, named as *R. dilectus*, represents populations with $2n = 46$ or 48 and occurs in the eastern and northern more mesic parts of the range. This second clade is comprised of two subgroups, which can be considered as subspecies: *R. d. dilectus* ($2n = 46$) from the northern parts of the range (Uganda [Mt Elgon], Malawi [Nyika Plateau, Mt Mlanje], Zimbabwe [Inyanga Highlands] and N South Africa [three known localities centred on Limpopo Province]) and *R. d. chakae* ($2n = 48$) from NE and SE South Africa. The two 'subspecies' appear to be parapatric in N South Africa, but presumably not syntopic. Information is not available for the many isolated populations in East Africa (see Distribution). Synonyms: 27 (details in Musser & Carleton 2005). Subspecies: uncertain (see comments above). Chromosome number: $2n = 46$ or 48 .

Description Small mouse with black and cream lateral stripes. Dorsal pelage harsh, yellowish-brown to speckled buff (see also Geographic Variation); hairs black at base, yellowish-brown at tip; numerous thick black guard hairs darken dorsal pelage. No black mid-dorsal stripe (cf. *Lemniscomys*). Whitish or cream lateral stripe, one on either side of mid-dorsal line, from behind ears to base of tail, each bordered by a black or brown lateral stripe above and below (hence four black stripes). Ventral pelage paler than dorsal pelage, without black guard hairs. Head similar in colour to dorsal pelage, with a longitudinal median black stripe from between eyes to between ears. Ears well covered with short reddish-brown or orange hairs. Chin, throat and abdomen paler than head, or off-white; bases of hairs dark grey. Fore- and hindfeet paler than dorsal pelage, soles of hindfoot darkly pigmented. Tail comparatively short (ca. 80% of HB; see also below) with sparse short hairs, black above, yellowish-brown or grey below. Nipples: $2 + 2 = 8$.

Geographic Variation Pelage colour and tail length vary geographically. In southern Africa, individuals from eastern areas are dark grizzled greyish-buff, with black lateral stripes; those from the western (drier) areas are whitish-grey with reddish-brown lateral stripes. In parts of Botswana, dorsal pelage pale yellowish-

buff, lateral stripes brown. One melanistic specimen recorded from Molopolo, Botswana (specimen in TM). Mean head and body length, and tail, vary according to locality and climate; e.g. Zimbabwe: HB: 100 mm, T: 85 mm; Botswana: HB: 105 mm, T: 106 mm (Smithers 1983); Mt Elgon: HB: 107–112 mm, T: 78–80 mm (Clausnitzer 2003). Variation in size is positively correlated with mean minimum temperature of the coldest month (Yom-Tov 1993). Where *Rhabdomys pumilio* is parapatric with *Lemniscomys* spp. (also a diurnal herbivore but often larger in size), individuals are significantly smaller than those from regions where *Lemniscomys* does not occur. Possibly two subspecies (see Taxonomy above).

Similar Species

Lemniscomys spp. Black mid-dorsal stripe; many pale-coloured lateral stripes (sometimes continuous, sometimes broken into spots) on flanks in most species.

Distribution Endemic to Africa. Widespread in South-West Arid, South-West Cape and Highland BZs, SW Zambezan Woodland BZ, and in Afromontane–Afroalpine BZ, from southern Africa to eastern Africa. Recorded extensively in South Africa and Namibia. Patchy and discontinuous in Swaziland, S Mozambique, E Zimbabwe, C and S Angola, S Botswana, Zambia (Nyika Plateau), Malawi (Mt Mlanje, Nyika Plateau), SE DR Congo, Tanzania (highland areas including Mt Kilimanjaro, Livingstone Mts, Uzungwa Mts, Mt Rungwe, Poroto Mts and Ngorongoro crater rim), Kenya (Mt Kenya and central highlands) and Uganda (Mt Elgon). Recorded from close to sea level

Rhabdomys pumilio

in South Africa, to 3500–4200 m on Mt Elgon and ca. 4000 m on Mt Kenya. Occurs over a range of rainfall regimes from <100 mm/year in Namibia, to >1200 mm/year in E Zimbabwe and W Mozambique, and to ca. 3000 mm/year on Mt Mlanje (Malawi). (See also genus profile.)

Habitat In southern Africa, recorded from bush and savanna habitats, dry river beds, high grassveld, karoo, succulent karoo, forest and woodland ecotones, edges of agricultural lands, and montane grasslands up to 2700 m. Confined to montane grasslands and swamps, and afroalpine habitats, in northern part of geographic range (e.g. in Malawi [Happold & Happold 1989b] and Mt Elgon, Uganda [Clausnitzer 2001]).

Abundance Widespread and fairly common species in southern Africa, and often the most numerous species of small mammal (rodents and shrews), e.g. ca. 40–70% in grasslands and shrublands at 1500–1700 m in the Drakensburg Mts, South Africa (Rowe-Rowe & Meester 1982a), and by far the most numerous species in river bed, dune and plateau habitats in Namibia (Nel 1978). In high altitude grasslands of Malawi, *Rhabdomys* was the most numerous species of small rodent (47%, $n = 45$; 5 spp.) on the Nyika Plateau, and the third most abundant species (22%, $n = 46$; 6 spp.) on Mt Mlanje (Happold & Happold 1989b). Density also varies greatly by locality and season: 9–13/ha (Nyika Plateau, Malawi), 2–8/ha (Mt Mlanje, Malawi), up to 10/ha (Mt Elgon, Uganda), up to 14/ha (Mt Kilimanjaro, Tanzania) and 6–34/ha (Kenya) (Delany & Roberts 1978, Happold & Happold 1989b, Shore & Garbett 1991, Clausnitzer 2003). In some habitats densities may be even greater, especially when (temporarily) there are many juveniles in the population (e.g. 37–171/ha in succulent karoo, South Africa; Schradin & Pillay 2005b). Biomass in Eastern Cape Province, South Africa, fluctuates greatly within and between years by several orders of magnitude (e.g. 0.1–1.0 kg/ha; Perrin 1980b).

Adaptations Terrestrial and scansorial. Diurnal and crepuscular. Constructs shallow burrows in some areas, usually not deeper than ca. 50 cm), with the entrance hidden under vegetation. Runways radiate from the burrow entrance, and are usually well hidden under grass cover. Nests are built in burrows, clumps of grass or amongst low-growing bushes. In contrast, in the Kalahari (Nel 1978), grasslands (Choate 1971) and succulent karoo of South Africa, nests are typically above ground and burrows are not constructed (Schradin & Pillay 2004). In the southern Kalahari and Namib deserts, and the succulent karoo, these mice climb in low bushes (for foraging), a habitat not utilized by other syntopic small mammals (Nel 1978). The large geographic range, from hot semi-arid grasslands to damp cold sub-alpine moorlands, indicates very wide habitat tolerance. Diurnal activity and acclimation to cold regulate heat production and body temperature (Haim & Fourie 1980). Body fat fluctuates irregularly during the year, mostly in response to ingestion of nutritious foods and/or seasonal change. Insects provide additional fat and proteins during the breeding season (Perrin 1980a, b).

Foraging and Food Opportunistic omnivore. Individuals in semi-arid succulent karoo habitats forage alone (Schradin & Pillay 2004). Diet varies seasonally (Perrin 1980a, Churchfield 1985) and is predominantly granivorous in many areas (Brooks 1974, Rowe-Rowe & Meester 1982b, Kerley 1989). Percentage composition of

the diet, in terms of green plant material, seeds and insects, varies temporally; for example, in Eastern Cape Province, South Africa, the diet in mid-summer (Jan–Feb) was 83% insects, 2% seeds, 0% fruits, 7% leaves and 9% stems; in mid-winter (Jun–Jul) it was 0% insects, 19% seeds, 49% fruits, 4% leaves and 27% stems (Perrin 1980a). Similar changes in diet are recorded in other localities (Rowe-Rowe 1986). Also eats fruits of *Ziziphus mucronata* (buffalo thorn), *Grewia* spp. (raisin bush) and the pods of *Acacia* spp. in Botswana (Smithers 1971). In some localities, feeds on the succulent bracts of low-growing *Protea* flowers, and probably assists in pollination (Rourke & Wiens 1977). Snails and worms are eaten occasionally. In the succulent karoo, feeds on leaves and fruits from shrubs (*Zygophyllum retrofractum*), wildflowers (during spring) and succulents. At some times of the year, especially in winter, diet includes roots and bark of trees in commercial *Pinus patula* plantations, causing considerable damage (Taylor & Perrin 1996). The periods of the year when insects form a large proportion of the diet are correlated with the highest rates of pregnancy (Perrin 1980a, b).

Social and Reproductive Behaviour Social behaviour varies according to habitat and population density. In non-arid habitats of South Africa, individuals are solitary and territorial (Willan 1982) and levels of aggression are not density-dependent (Ercoli 1994). Adult ♂♂ are more aggressive and less amicable than adult ♀♀ (Perrin *et al.* 2001). Adults, particularly ♀♀, are inhibited from attacking juveniles and subadults owing to kin-selection. They are less aggressive to kin than to unknown individuals within a population (Perrin *et al.* 2001).

In semi-succulent Karoo, individuals live in communal groups, typically comprised of one adult breeding ♂, four adult breeding ♀♀ and 5–28 non-breeding adults (progeny of the breeding ♀♀). Each group lives in a large surface grass nest within a bush (typically *Zygophyllum retrofractum*). Interactions between members of the group are mostly amicable; for example sitting in bodily contact, sniffing at each other and allogrooming. Territorial behaviour (chasing and fighting) is exhibited by all group members. Territorial aggression is greatest in front of the group nest and lower at territory boundaries. Males are more aggressive towards ♂♂ of other groups than towards ♀♀ of other groups. Females are aggressive towards strangers of both sexes. Behavioural characters of *Rhabdomys pumilio* suggest it is a 'territorial group-living solitary forager' (Schradin 2004). Under conditions of extreme low population density in the succulent karoo (as during the exceptional drought of winter 2003), the social system changes from a social to a solitary life-style (as typically exhibited by conspecifics living in grasslands), but reverts to group living with increasing population density (C. Schradin & N. Pillay unpubl.). This species is a good example of the way in which social behaviour varies with the environment (in particular with food abundance, availability of suitable nesting sites and the possibility of sun-basking): individuals living in arid habitats form territorial groups (up to 30 adult mice) but forage alone, whereas individuals living in mesic environments are solitary, and have exclusive territories although the territory of a ♂ overlaps the territories of several ♀♀ (Schradin 2005).

Rhabdomys pumilio exhibits paternal care of the young. In group-living individuals from the succulent Karoo, ♂♂ participate in looking after the young (huddling, retrieving, grooming) in a similar way to ♀♀ (Schradin & Pillay 2003). There is some evidence for

allonursing (a ♀ suckling young other than her own) (Schradin & Pillay 2004).

In group-living populations of the succulent karoo, individuals of one group have largely overlapping home-ranges, and the home-range areas for each sex are not statistically different (Schradin & Pillay 2004). Radio-tracking revealed a home-range size of $1305 \pm 225 \text{ m}^2$ for ♂♂ and $912 \pm 93 \text{ m}^2$ for females. In grasslands of KwaZulu–Natal, home-ranges are much larger, and ♂♂ ($12,466 \pm 2000 \text{ m}^2$) have significantly larger home-ranges than ♀♀ ($5760 \pm 1098 \text{ m}^2$; Schradin & Pillay 2005a).

Reproduction and Population Structure In South Africa, reproduction is seasonal and occurs in summer after rainfall and when nutritious food (especially insects) is available; reproduction is inhibited in winter and is associated with a low protein vegetarian diet, little rainfall and cool temperatures (Brooks 1974, Smithers & Wilson 1979, Perrin 1980b, Henschel *et al.* 1982). In the succulent karoo (with winter rain), reproduction occurs during three months in spring (mid-Aug to mid-Nov) after winter rains, but not during the dry summer (Schradin & Pillay 2005b). Reproduction in Zimbabwe is also seasonal (Smithers & Wilson 1979). Embryo number: 4.91 ± 1.73 ($n = 21$; South Africa; Perrin 1980b); 6.5 (3–10, $n = 42$ litters in captivity; Brooks 1982); 4.7 (3–6, $n = 6$; Zimbabwe; Smithers & Wilson 1979); 4.5 (3–7, $n = 22$; South Africa – Drakensberg Mts; Rowe-Rowe & Meester 1982b); 6.1 (1–11, $n = 24$; South Africa – KwaZulu–Natal; Taylor 1998); 3.6 (3–4, $n = 5$; Uganda – Mt Elgon; Clausnitzer 2003). Litter-size can be reduced to two young under conditions of low food availability, such as in the Namib Desert (Krug 2002) or in the succulent karoo after extreme drought (C. Schradin & N. Pillay unpubl.). Average gestation: 25 days (Brooks 1974). Females have a postpartum oestrus (Choate 1971). At birth, young are altricial and weigh 2.5 g. Eyes open Day 7–8. Weaned Day 16. Sexual maturity ca. 2 months (Brooks 1974). Young do not nipple-cling. *Rhabdomys pumilio* is considered to be a comparatively r-selected species (Perrin 1980b).

Population structure fluctuates on an annual basis. In Eastern Cape Province, South Africa, during summer and early winter (Jan–Jun), the population (as indicated by tooth wear and eye-lens weight) is composed of juveniles and older breeding adults. In late summer and early winter (Jul–Oct), younger animals form the majority of the population because of the high mortality of older animals. Prior to reproduction in spring (Nov–Dec), population is composed of the young of the previous year (now ca. 8–11 months) and no juveniles (Perrin 1979). Population numbers fluctuate greatly during the year

(see above). In the succulent karoo, reproduction occurs in spring by individuals born the previous spring. Juveniles first appear in Sep (16% of the population) and comprise ca. 50% of the population in Oct (when population densities are highest – see above) and ca. 10% in Dec when the breeding season has terminated (Schradin & Pillay 2005b). Mice lose 12% of body weight during the dry summer, and mortality is highest during the following cold and wet winter. However, the annual mortality of ca. 80% is lower than in grasslands (ca. 93%). No information available on reproduction and population structure in other parts of the geographic range.

Predators, Parasites and Diseases Many predators have been recorded, including several species of snakes, several species of owls and diurnal raptors, servals, wildcats, jackals, genets and mongooses. In some areas, this species is also eaten by humans, e.g. in KwaZulu–Natal (South Africa) and Mozambique. Many ectoparasites have been recorded, including mites, chiggers, fleas (41 spp.; Zumpt 1961, 1966) and ticks (11 spp.; Theiler 1962). Endoparasites include nine species of tapeworms and six species of round worms. Full lists of parasites are given in De Graaff (1981).

Conservation IUCN Category: Least Concern.

This common and abundant species is not threatened in the southern part of its range. However, the small populations on isolated mountains in East Africa require adequate conservation.

GENUS *Stenocephalemys*

Ethiopian Rats

Stenocephalemys Frick, 1914. Ann. Carnegie Mus., 9: 7. Type species: *Stenocephalemys albocaudata* Frick, 1914.

The genus *Stenocephalemys* is endemic to Ethiopia, mostly in the Afromontane–Afroalpine BZ, and contains four species (Table 40); two species live in high altitude grassland and moorlands (2400–4400 m) and two live in bush and forest habitats at lower altitudes (1500–3000 m).

Species in this genus are medium to large rats with long tails (ca. 86–123% of HB). Skull with curved braincase (when viewed laterally), well-developed zygomatic plate, thick wide zygoma, anterior palatal foramina reach to mid-line of M¹, orthodont incisors without groove, relatively large molar toothrow, and narrow interorbital constriction

Table 40. Species in the genus *Stenocephalemys*. Arranged in order of increasing mean head and body length. All measurements in mm. (n. d. = no data.)

| Species | HB
mean
(mm) | T
% of HB | WT
average
(g) | M ¹ –M ³
(mm) | Interorbital constriction
(shape in cross-section) | Notes |
|-----------------------|--------------------|--------------|----------------------|--|---|--|
| <i>S. albipes</i> | 132 | 125% | 59 | 5.5 | Rounded | Widely distributed 1500–3000 m east and west of Rift Valley |
| <i>S. ruppi</i> | 131 | 122% | 60 | 6.7 | Rounded | Gughe Mts, west of Rift Valley only. Rare |
| <i>S. griseicauda</i> | 154 | 93% | 99 | 6.8 | Rounded, flat dorsally | High plateaux east and west of Rift Valley. 2400–3900 m |
| <i>S. albocaudata</i> | 164 | 86% | 130 | 7.9 | Square | High plateaux of Bale and Arssi Provinces, east of Rift Valley. 3000 m |

Stenocephalemys griseicauda.

(Figure 85). This arrangement (stenocephaly) positions the eyes in a more dorsal position than in most other small rodents. Skull shape within species of the genus appears to be correlated with altitude, stenocephaly being more pronounced in higher altitude species than in those living at lower altitudes (Fadda & Corti 2000) (Figure 86). Pelage texture is silky to woolly. Dorsal pelage is sandy-brown, ventral pelage is paler; there are faint darker rings around the eyes, prominent thin ears and unremarkable feet. Superficially *Stenocephalemys* looks very much like *Mastomys*, *Myomyscus* and *Praomys*.

Species of the genus are nocturnal. Species at higher altitudes have a thick woolly pelage. The diet is granivorous and herbivorous, but there are no detailed quantitative studies for most species. The period of reproduction varies by species and altitude; at lower altitudes reproduction occurs throughout the year (*S. albipes*); at higher altitudes it is seasonal, mainly during the wet season but not during the cold season (*S. albocaudata*, *S. griseicauda*). Recruitment of young animals into the population is low. Two species are abundant (*S. albipes*, *S. albocaudata*) and are an important prey for raptors, but not for Ethiopian Wolves (see *Arvicanthus blicki* and *Lophuromys melanonyx*).

The genus was erected for *S. albocaudata* in 1914. Another species, *S. griseicauda*, was recognized in 1972. A third species, *S. albipes*, was previously allocated to the genus *Praomys*, and later to *Myomys* (now *Myomyscus*) (see Yalden *et al.* 1976, Musser & Carleton 1993). *Stenocephalemys ruppi*, regarded originally as a narrow-headed form of *S. albipes*, was described as a full species in 1983. The four species are now considered to represent a group of rodents endemic to Ethiopia. The genus is phylogenetically related to species of *Praomys*, *Mastomys*, *Myomyscus*, *Heimyscus* and *Hylomyscus*

Figure 85. Skull and mandible of *Stenocephalemys albocaudata* (BMNH 72.1196).

Figure 86. Cross section of the interorbital region of the skull of *Stenocephalemys*. (a) rounded, e.g. *S. albipes*, *S. ruppi*; (b) square, e.g. *S. albocaudata*, *S. griseicauda* (after Yalden *et al.* 1976).

(Lecompte *et al.* 2002b). Analysis of allozymes, karyology, mitochondrial 16S rRNA and mitochondrial DNA cytochrome *b* gene sequences link *S. albipes*, *S. albicaudata* and *S. griseicauda* (*S. ruppi* not included in the analysis) and indicate that these species form a monophyletic group (Lavrenchenko *et al.* 1999, 2000, Fadda & Corti 2000), which is distinct from *Praomys* and *Myomyscus* (= *Myomys*). *Stenocephalemys griseicauda* is more closely related to *S.*

albipes than to *S. albicaudata*. Detailed analysis of the genus is given by Musser & Carleton (2005).

The four species are distinguished by size, skull characters and distribution.

D.W. Yalden

Stenocephalemys albipes WHITE-FOOTED ETHIOPIAN RAT (WHITE-FOOTED STENOCEPHALEMYS)

Fr. Rat d'Éthiopie à pieds blancs; Ger. Weissfüssige Äthiopien-maus

Stenocephalemys albipes (Rüppell, 1842). Mus. Senckenberg. 3: 107. Massawa [?], Ethiopia. (The type locality, at sea level, is misleading since the species is not currently known from below ca. 800 m.)

Taxonomy Originally described by Rüppell as *Mus albipes*, but usually allocated to the genus *Myomys* or *Praomys* (Yalden *et al.* 1976, Yalden 1988). Karyologic al analysis (Corti *et al.* 1995, 1999), DNA mitochondrial cytochrome *b* sequences (Lecompte *et al.* 2002b) and other studies indicate that *S. albipes* clusters with *S. albicaudata* and *S. griseicauda* in a monophyletic group confined to the Ethiopian plateaux. Synonyms: *alettensis*, *ankoberensis*, *leucopus*, *minor*. Subspecies: none. Chromosome number: $2n = 46$, $FN = 50-53$ (Corti *et al.* 1999).

Description Medium-sized, silky-furred rat, on average much smaller than *S. albicaudata* and *S. griseicauda*, comparable in size with *Mastomys* spp. in Ethiopia. Pelage sleek and long (hairs 10–12 mm). Dorsal pelage sandy-brown, slightly darker towards mid-line; hairs dark grey at base, sandy-brown on terminal third. Juveniles greyer than adults, gaining sandy colour by about three months of age. Ventral pelage pale grey; hairs dark grey at base, white on terminal third. Colour of dorsal and ventral pelage sharply delineated. Eye with faint dark ring. Ears grey, large, rounded, appearing naked but finely furred. Forelimbs small, brownish-grey. Forefeet white, with four digits. Hindfeet white above, with characteristic dark mark over metatarsals; Digits 1 and 5 short. Tail very long (ca. 125% of HB), bicoloured, lightly furred, appearing naked, black dorsally, white ventrally. Skull: interorbital constriction less marked than in congeners; rounded in cross-section (Figure 86). Nipples: $3 + 2 = 10$.

Geographic Variation None recorded.

Similar Species

- S. albicaudata*. Larger (mean WT: 130 g); mean M^1-M^3 : 7.9 mm; tail uniformly white, or white with grey patches, relative tail length ca. 86% of HB; interorbital constriction square in cross-section.
- S. griseicauda*. On average larger (mean WT: 99 g); M^1-M^3 : 6.8 mm; tail grey, relative tail length 93% of HB, darker dorsally than ventrally; interorbital constriction rounded laterally, but flat dorsally, in cross-section.
- S. ruppi*. Slightly larger (mean WT: 60 g); M^1-M^3 : 6.7 mm; tail grey, relative tail length 122% of HB, darker dorsally than ventrally; interorbital constriction more marked, rounded, in cross-section.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of Ethiopia. Widely distributed in many mid-elevation highland habitats

Stenocephalemys albipes

in Ethiopia, particularly at 1500–3000 m. May also occur in some lowland forest habitats at 1285 and 820 m (Yalden & Largen 1992; Afework Bekele 1996a), but not known to occur in grasslands at 3700 m in the Simien Mts nor in grasslands at lower altitudes (Yalden & Largen 1992; Afework Bekele 1996a, Afework Bekele & Corti 1997) (see also below).

Habitat Recorded from a wide range of habitats including bush, grasslands, forest and *Erica* scrub. Trapping shows that forest habitats are preferred to shrub and grassland (Afework Bekele 1996b). In areas of human disturbance, occurs in the 'living fences' surrounding tukuls (local homesteads).

Abundance The most common rodent trapped at altitudes above 1500 m within and close to forest habitats, especially at 2800–3000 m. Probably the second most widespread rodent in Ethiopia after *Lophuromys flavopunctatus*. In Menagesha State Forest, comprised 54% of rodents in all habitats, and 71% in forest locations (Afework Bekele 1996a). With increasing altitude, forms a higher percentage of

the population of small mammals in its preferred habitats (Afework Bekele & Corti 1997).

Adaptations Nocturnal and terrestrial. Semi-arboreal activity has been observed on trees close to the ground.

Foraging and Food Herbivore and frugivore. In bushland and scrub habitats in Menagesha State Forest, diet (as indicated by occurrence in stomachs) was berries of *Carissa edulis* (in 94% of stomachs) and green leaves (38%) (n = 53 stomachs). In forest habitats, the diet was berries of *Olea* (in 60% of stomachs), *Juniperus* (57%), *Rosa abyssinica* (25%), *Rubus* (13%) and green leaves (63%) (n = 60 stomachs) (Afework Bekele 1996b). Animal material in stomachs was insignificant.

Social and Reproductive Behaviour The mean home-range length was 29 ± 12.9 m for ♀♀, and 65 ± 31.2 m for ♂♂. Male home-range lengths overlapped, while those of ♀♀ did not overlap.

Reproduction and Population Structure Reproduction occurs throughout the year with the highest pregnancy rates during the end of wet season (Sep and Nov). Reproductively active ♂♂ (with scrotal testes) were recorded throughout the year. Gestation: 23 days. Embryo number: 5 (2–8, n = 18 pregnancies). Litter-size: 4.1 (2–6, mode 5, n = 42 litters). At birth, young are naked and weigh ca. 3 g. Ear pinnae unfold Day 4–5. Pelage visible Day 7–10. Incisors (lower) erupt Day 10–12, (upper) Day 13–17. Eyes open Day 13–18. Weaned at Day 24–29. Weight gain is rapid up to eight weeks, and slower thereafter, and after weight of 45 g. Recruitment rate of young into the population is usually less than 20% (perhaps

due to heavy predation). Survival rate for adults was less than a year in the wild and three years in captivity (Afework Bekele 1995).

Predators, Parasites and Diseases Nocturnal predators such as owls may be a controlling factor on population numbers. Nematode worms found in at least 17 (of 60) stomachs, with up to ten worms per stomach.

Conservation IUCN Category: Least Concern.

Although deforestation has (and is) continued at an alarming rate, White-footed Mice survive well on the forest fringes and in the bush where *Carissa edulis*, *Rosa abyssinica* and *Rubus* are common, and close to human habitations.

Stenocephalemys albicaudata WHITE-TAILED ETHIOPIAN RAT (WHITE-TAILED STENOCEPHALEMYS)

Fr. Rat d’Ethiopie à queue blanche; Ger. Weisschwänzige Äthiopien-maus

Stenocephalemys albicaudata Frick, 1914. Ann. Carnegie Mus. 9: 8, pls 1–2. Inyala Camp, Chilalo Mts, Ethiopia (ca. 07° 50' N, 39° 20' E).

Taxonomy *Stenocephalemys albicaudata* is the nominate species in the genus. It is closely related to the other species in the genus, *S. griseicauda* and *S. albipes* (formerly *Myomys albipes*) and *S. ruppi*. The chromosome number (2n = 54) is the same as in *S. griseicauda* (Lavrenchenko *et al.* 1997). On the basis of 16S rRNA sequences and allozyme data, this species is more distinct from *S. griseicauda* and *S. albipes* than they are from each other; morphologically and cytogenetically, *S. albicaudata* is much closer to *S. griseicauda* than to *S. albipes*. Synonyms: none. Chromosome number: 2n = 54, FN = 60–62 (Corti *et al.* 1999; Lavrenchenko *et al.* 1999).

Description Large, soft-furred rat, larger on average than the other three species in the genus. Pelage woolly and dense, uniformly longer (hairs 16–18 mm on mid-back) and softer than in *Praomys* and *Myomyscus*. Dorsal pelage dark sandy-brown to ginger (adults appearing much brighter than *S. griseicauda*); hairs dark grey at base, sandy on tip; many slightly longer black-tipped hairs especially on mid-dorsal line. Flanks paler, brownish, without black-tipped hairs. Ventral pelage greyish-white; hairs grey with off-white tip; pure

white mid-ventral stripe in some individuals. Dorsal and ventral pelage delineated by a sharp yellowish line. Eyes with dark rings. Ears grey, prominent, lightly furred. Fore- and hindfeet white. Tail long (86% of HB), scaly, almost naked but with short white hairs; appearing uniformly white or white with grey patches proximally. Juvenile pelage much greyer than in adults. Skull: interorbital constriction narrow, squared off dorsally in cross-section (Figure 86). Nipples: 3 + 2 = 10.

Geographic Variation None recorded.

Similar Species

S. albipes. Much lighter (mean WT: 59 g); mean M¹–M³: 5.5 mm; tail bicoloured, black dorsally and white ventrally, relative tail length ca. 125% of HB; interorbital constriction rounded in cross-section.

S. griseicauda. On average lighter (mean WT: 99 g); M¹–M³ shorter; tail grey, relative tail length 93% of HB, darker dorsally than ventrally; interorbital constriction rounded laterally, but flat dorsally, in cross-section.

S. ruppi. Much lighter (mean WT: ca. 60 g); M^1 – M^3 shorter; tail dark grey above, pale below, relative tail length 122% of HB; interorbital constriction rounded laterally, but flat dorsally, in cross-section.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of Ethiopia. Confined to the high plateaux in Bale and Arssi (Arussi) Provinces, SE Ethiopia, at 3000–4377 m. Not known from west of the Rift Valley (Yalden *et al.* 1976, Yalden & Lagen 1992).

Habitat Typically found in upland moorland, above 3500 m (Yalden 1988), but extends to lower grasslands along river valleys. Habitat preference distinguishes this species from both *S. albipes* (a forest species) and *S. griseicauda* (a scrub species). In the Web Valley, Bale, commonly found in *Alchemilla* pastures and mesa slopes dominated by low *Artemisia* and *Helichrysum* scrub, which provide good cover.

Abundance The most common rodent on the high plateau, above 4000 m, contributing 32% (994 of 3083) of the rodents caught in Bale Province (Sillero-Zubiri *et al.* 1995a). Density estimated at 42/ha (16–60/ha in different months) in the Web Valley grasslands and 26/ha (16–44/ha in different months) in the moorland of the Sanetti plateau (Sillero-Zubiri *et al.* 1995a). Commonly syntopic with diurnal species, e.g. *Arvicanthis blicki*, *Lophuromys melanonyx* and *Tachyoryctes macrocephalus*.

Adaptations Nocturnal (over 99% of 752 captures were at night; Sillero-Zubiri *et al.* 1995a). Large size (compared with other Ethiopian rodents) and woolly pelage are assumed to be responses to the low night-time temperatures at high altitude (Rupp 1980, Yalden & Lagen 1992, Sillero-Zubiri *et al.* 1995a). Narrow interorbital region causes the eyes to face more dorsally than in other species of the genus, which might be an adaptation for detecting raptors in its open upland habitat (Yalden & Lagen 1992).

Foraging and Food Dentition and habitat suggest a granivorous and herbivorous diet; no detailed information.

Social and Reproductive Behaviour No information.

Reproduction and Population Structure In Bale Province, pregnant animals were found during wet season (May–Oct) with a sharp peak in reproductive activity in May–Jun. No pregnancies recorded during the dry season (Dec–Apr). Very young animals (<40 g) found mainly Aug–Jan. Beginning of the wet season probably triggers reproduction (Sillero-Zubiri *et al.* 1995a). Embryo number: 3.59 ± 0.93 , $n = 27$ ♀♀. Even when most numerous in Aug–Nov, juveniles comprise only 30% of the population and ca. 10% in Feb–Jul (Sillero-Zubiri *et al.* 1995a), suggesting a low rate of recruitment.

Predators, Parasites and Diseases Nocturnal habits probably protect these rats from the largely diurnal predators such as raptors and from Ethiopian Wolves *Canis simensis* (which feed mainly on the

Stenocephalemys albocaudata

diurnal *Arvicanthis blicki* and *Lophuromys melanonyx*). Ethiopian Wolves avoided these rats in ‘cafeteria’ tests (Sillero-Zubiri & Gotelli 1995). Forms the main prey of Abyssinian Long-eared Owls *Asio abyssinicus* (53% by prey number, 63% by prey mass; Yalden 1973), and is probably eaten also by other owls.

Conservation IUCN Category: Least Concern.

Lives at higher altitudes than the majority of Ethiopians and their livestock, and hence its habitat should be relatively safe from destruction; however, the limited range of the habitat should class this species as ‘vulnerable’. Preferred habitat is protected within the proposed Bale Mountains National Park.

***Stenocephalemys griseicauda* GREY-TAILED ETHIOPIAN RAT (GREY-TAILED STENOCEPHALEMYS)**

Fr. Rat d'Éthiopie à queue grise; Ger. Grauschwänzige Äthiopien-maus

Stenocephalemys griseicauda Petter, 1972. Mammalia 36: 171. Dinshu, Bale Mts, Ethiopia.

Taxonomy Distinguished from *S. albicaudata* (the nominate species of *Stenocephalemys*) by its smaller size and grey tail (Petter 1972a). Synonyms: none. Chromosome number: $2n = 54$. Two chromosomal forms in the Bale Mts may represent cryptic species (Lavrenchenko *et al.* 1997). One chromosomal form (from high altitudes) has a metacentric X chromosome, and the other (medium altitudes) has a submetacentric X chromosome. These two forms are also distinguished by several other genetic polymorphisms.

Description Large, soft-furred rat, intermediate in size between *S. albipes* and *S. albicaudata*. Pelage woolly and long (hairs ca. 1415 mm on mid-back); uniformly longer and softer than in *Praomys* and *Myomyscus*. Dorsal pelage sandy-brown to dull brown, darker over the mid-line; hairs dark grey at base, sandy-brown at tip; many slightly longer black-tipped hairs, especially on mid-dorsal line. Flanks paler than back. Ventral pelage greyish-white; hairs dark grey at base, off-white or pale grey at tip. Faint dark ring around eyes. Ears grey, prominent, slightly furred. Fore- and hindfeet off-white or pale brown. Tail moderately long (ca. 93% of HB), grey above or all over. Skull: mean M^1-M^3 : 6.8 mm; interorbital constriction narrow, flat dorsally but rounded laterally in cross-section (Figure 86). Nipples: not known.

Geographic Variation None recorded except for altitudinal variation in chromosomal and genetic characters (see Taxonomy).

Similar Species

S. albipes. On average lighter (mean WT: 59 g); mean M^1-M^3 shorter; tail bicoloured, black dorsally and white ventrally,

relative tail length ca. 125% of HB; interorbital constriction rounded in cross-section.

S. albicaudata. On average heavier (mean WT: 130 g); mean M^1-M^3 longer; tail uniformly white, or white with grey patches, relative tail length 86% of HB; interorbital constriction square in cross-section.

S. ruppi. Lighter (mean WT: 60 g); tail bicoloured, black dorsally and white ventrally, relative tail length ca. 122% of HB; interorbital constriction rounded in cross-section.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of Ethiopia. Confined to the high plateaux of Ethiopia, at 2400–3900 m. Widespread both east and west of the Rift Valley from Simien in the north to Bale in the south (Yalden *et al.* 1976, Yalden & Largen 1992).

Habitat Typically found in upland grasslands (dega) and scrub, at 2900–3500 m, extending uphill into the edge of moorland (Yalden 1988, Sillero-Zubiri *et al.* 1995a). Habitat preference separates this species ecologically from both *S. albipes* (forest species) and *S. albicaudata* (moorland species), though their general distributions overlap. In the Web Valley, Bale Province, preferred habitat is mesa slopes dominated by low *Artemisia* and *Helichrysum* scrub, which provide good cover (Sillero-Zubiri *et al.* 1995a). Often occurs with *Lophuromys flavopunctatus*.

Abundance Common in upland grassland communities, contributing 23% of the rodents caught in appropriate habitats in Bale (Yalden 1988).

Adaptations Nocturnal (97% of 71 captures being made at night; Yalden 1988, Sillero-Zubiri *et al.* 1995a). Large size (compared with other Ethiopian rodents) and woolly pelage are assumed to be adaptations to the low night-time temperatures at high altitude (Rupp 1980, Yalden & Largen 1992, Sillero-Zubiri *et al.* 1995a). Narrow inter-orbital region causes the eyes to face more dorsally, which might be an adaptation for detecting raptors in the open upland habitat (Yalden & Largen 1992).

Foraging and Food Dentition and habitat suggest a granivorous and herbivorous diet; no detailed information available.

Social and Reproductive Behaviour No information.

Reproduction and Population Structure In Simien, pregnant animals were found just before, during and immediately after the wet season (May–Dec), but not in the dry cold season (Jan–Apr). Very young animals (<40 g) were found mainly in Sep–Dec (Müller 1977).

Predators, Parasites and Diseases Nocturnal habits probably protect these rats from largely diurnal predators such as raptors and Ethiopian Wolves *Canis simensis*. Probably preyed upon by various owls, a suggestion which requires confirmation.

*Stenocephalemys griseicauda*

Conservation IUCN Category: Least Concern.

Although relatively common, lives in habitats that suffer from continuing destruction by many humans and their livestock.

Stenocephalemys ruppi RUPP'S ETHIOPIAN RAT (GUGHE HIGHLANDS RAT, RUPP'S STENOCEPHALEMYS)

Fr. Rat d'Ethiopie de Rupp; Ger. Rupp's Äthiopien-maus

Stenocephalemys ruppi (Van der Straeten and Dieterlen, 1983). Ann. Mus. Roy. Afr. Centr., Sci. Zool. 237: 121. Bonke, N. of Bulta, Gemu-Gofa, Ethiopia. 2800–3200 m.

Taxonomy First described as *Praomys ruppi*, then placed in the genus *Myomys*. Subsequently allocated to the genus *Stenocephalemys* on account of its intermediate morphology between *S. albipes* and *S. griseicauda*, particularly on the character of the interorbital region, and because (like the other species in genus) it is an Ethiopian endemic (see Musser & Carleton 2005). Considered as a narrow-headed form of *S. albipes* (Rupp 1980, as *M. albipes*) and closely related to it (Van der Straeten & Dieterlen 1983). Perhaps not distinguishable from *S. albipes*, but encompassed within the range of variation of that species (Fadda & Corti 2000; M. Corti pers. comm.). Synonyms: none. Chromosome number: not known.

Description Medium-sized, soft-furred rat, intermediate in size and other respects between two other endemic Ethiopian rodents, *S. albipes* and *S. griseicauda*. Dorsal pelage sandy-brown; hairs dark grey basally, uniform sandy-brown distally. Ventral pelage greyish-white; hairs dark grey basally, white distally. Sharp, yellowish delineation along flanks between dorsal and ventral colours. Ears grey, prominent, lightly furred. Forefeet white, hindfeet all white or with dark patch over metatarsals. Tail very long (ca. 122% of HB), dark grey above, pale below. Skull: mean M¹–M³: 6.65 mm; interorbital constriction narrow, rounded in cross-section (Figure 86). Nipples: 3 + 2 = 10.

Geographic Variation None recorded.

Similar Species

S. albipes. M¹–M³ shorter; tail more distinctly bicoloured, black dorsally and white ventrally, relative tail length ca. 125% of HB; interorbital constriction rounded in cross-section.

S. albicaudata. M¹–M³ longer; tail uniformly white, or white with grey patches, relative tail length 86% of HB; interorbital constriction square in cross-section.

S. griseicauda. Tail grey, relative tail length 93% of HB, darker dorsally than ventrally; interorbital constriction rounded laterally, but flat dorsally, in cross-section.

Stenocephalemys ruppi

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of Ethiopia. Confined to the Gughe Mts, west of the Rift Valley on the southern plateaux of Ethiopia, at 2800–3200 m. Syntopic with *S. albipes* (Yalden & Lagen 1992).

Habitat Montane forest and scrub, a habitat shared with *S. albipes*.

Abundance Presumably rare; described on the basis of nine specimens from the Gughe Highlands.

Remarks Presumably a nocturnal seed- and berry-feeder, like *S. albipes*.

Conservation IUCN Category: Data Deficient.

The very limited distribution in an area where there is a high density of humans suggests this species should be considered as vulnerable.

GENUS *Stochomys*

Target Rat

Stochomys Thomas, 1926. Ann. Mag. Nat. Hist., ser. 9, 17: 176. Type species: *Dasymys longicaudatus* Tullberg, 1893.

Stochomys longicaudatus.

Monotypic genus, widely distributed in the Rainforest BZ from W Nigeria to E DR Congo and W Uganda. The genus is 'rat-like' and characterized by medium body size, very long naked tail and large

heavily built skull (see *Stochomys longicaudatus* for further details). The type species of the genus was described as *Dasymys longicaudatus*. The genus *Stochomys* was created by Thomas (1926) to contain the single species, thus separating it from the genera *Dasymys*, *Rattus*, *Mus*, *Epimys* and *Aethomys* to which it had previously been allocated (see Rosevear 1969 for details).

The genus is closely related to (and morphologically similar to) *Dephomys* (Musser & Carleton 2005), although this relationship is uncertain (Van der Straeten 1984). Pelage, skull and dentition are similar to some species of *Aethomys*, suggesting that both genera belong to the same clade and are ecological equivalents in rainforest (*Stochomys*) and savanna (*Aethomys*) (Visser & Robinson 1986). On the basis of microcomplement fixation, *Stochomys* groups with *Hybomys*, both genera well removed from *Aethomys* (Watts & Baverstock 1995a). The systematic and phylogenetic position of *Stochomys* is ambiguous and far from clear, and awaits further study. The single species is *Stochomys longicaudatus*.

D. C. D. Happold

Stochomys longicaudatus TARGET RAT

Fr. Rat à collière; Ger. Zielscheibenratte

Stochomys longicaudatus (Tullberg, 1893). Nova Acta Reg. Soc. Sci. Uppsala, ser. 3, 16: 36. Cameroon.

Taxonomy Originally described in the genus *Dasymys*. The Target Rat has the dubious distinction of having been placed in six different genera at various times since its original description (Rosevear 1969; see also Genus profile). Now recognized as being the only species in the genus *Stochomys*. Can be confused with *Dephomys* except for differences in distribution. Synonyms: *hypoleucus*, *ituricus*, *sebastianus*. Subspecies: two of dubious validity. Chromosome number: not known.

Description Medium-sized robustly built rat with dense pelage and very long tail. Dorsal pelage reddish-brown to chocolate-brown; hairs almost unicoloured, sometimes pale grey at base. Dorsal pelage interspersed with long black shiny guard hairs (some with white tip), which extend beyond the contours of the body, especially on rump. These guard hairs project slightly upwards and backwards resembling

small arrows fired into a target. Flanks brownish-grey with fewer shorter guard hairs. Ventral pelage whitish or whitish-brown; hairs brownish on basal half, whitish on terminal half. Head large and broad, long vibrissae, large eyes, and large rounded ears sparsely covered with short hairs. Forefoot with five digits; Digit 1 very reduced, with nail. Hindfoot long and broad with five digits, each with claw; Digits 1 and 5 short; Digits 2, 3 and 4 long and subequal. Tail very long (ca. 146% of HB), small scales, seemingly naked but covered with small fine bristles. Dorsal pelage of juveniles greyish-brown with dark guard hairs visible. Moulting individuals often have patchy colouration. Skull: large and robust; GLS: >36 mm; supraorbital ridges well developed; anterior palatal foramina not reaching (or just reaching) level of M¹; width of palate at level of M¹ less than 1.5 times width of M¹; incisors well-developed, rather thick in anterior-posterior

Figure 87. Skull and mandible of *Stochomys longicaudatus* (HC 1349).

plane, opisthodont, not grooved; upper molar teeth canted outwards; t7 on M¹ absent; t9 of M¹ reduced to small displaced cusp; cusps on M¹ linear and almost laminate; t3 on M² very reduced and displaced (Figure 87). Nipples 1 + 2 = 6.

Geographic Variation Van der Straeten (1984) recognized two subspecies based on canonical analysis of skull characters: *S. l. longicaudatus* west of the Congo R. and *S. l. ituricus* to the east of the river. The validity of subspecies is questionable.

Similar Species

Dephomys defua. On average smaller, with smaller less-obvious guard hairs; geographic range only west of Dahomey Gap, not overlapping with *S. longicaudatus*.

Distribution Endemic to Africa. Rainforest BZ (West Central, East Central and South Central Regions). Recorded from W Nigeria to E DR Congo, including lower slopes of Rwenzori Mts. Populations on the periphery of main geographic range known from forest relicts in Togo and Dahomey (Robbins & Van der Straeten 1996), S Central African Republic (Genest-Villard 1980, Morvan *et al.* 1999, Malcolm & Ray 2000) and W Uganda (Delany 1975).

Habitat Primary and secondary rainforest, especially near rivers and streams; individuals have been found less commonly in oil palm plantations and cultivated land. Also occur in evergreen shady forests and gallery forests up to 800–1000 m on Mt Cameroon and in Rwenzori Mts (Misonne 1963). Considered as ‘gap specialists’ that take advantage of both natural and human-made secondary habitats within the Rainforest BZ, although not in open areas without cover. Significantly more abundant along primary and secondary logging roads than in unlogged forest (Malcolm & Ray 2000). Favours habitats characterized by relatively dense understorey, low tree species

Stochomys longicaudatus

diversity, low tree diameter, low sapling density and open canopy cover (Ray 1996, Malcolm & Ray 2000).

Abundance One of the rarest of rainforest rodents, comprising only 1–2% of the small terrestrial rainforest rodents trapped in Nigeria (Happold 1975b, 1977). In E DR Congo, relative abundance depended on habitat, e.g. 1.8% in cultivated land, 9% in forest near rivers, 1% on forested hills and 4% in oil palm plantations (Rahm 1967, 1972). In SW Central African Republic, comprised 3.2% of all captures (n = 704) along secondary logging roads, 0.2% (n = 458) in unlogged mixed-species forest, 1.5% in monodominant *Gilbertiodendron dewevrei* forest (n = 406) and 0.5% along streams (n = 200) (Ray 1996). At M’passa (Gabon), biomass was ca. 8 g/ha (Duplantier 1989), equivalent to ca. 1 individual/11 ha.

Adaptations Nocturnal and terrestrial or scansorial. A few individuals have been obtained in creepers 2–3 m above the ground. Individuals in captivity made spherical nests of shredded forest leaves and herbs (Happold 1987). In Dzanga-Sangha, Central African Republic, occurred only in lower strata (on ground and understorey at 2 m), and was more abundant in the understorey than on the ground and never captured in the canopy (Malcolm & Ray 2000).

Foraging and Food Analysis of stomach contents suggest a mainly vegetarian diet (Rahm 1966). Individuals in captivity ate fruits and seeds, as well as insects (Happold 1987). Diet was mostly fruit and seeds at Makokou (Gabon; Duplantier 1982) and at Mbaiki (Central African Republic; Genest-Villard 1980).

Social and Reproductive Behaviour May be nomadic, changing domiciles (and home-range) as conditions change. In W Nigeria most individuals in a study area were captured only once (Happold 1977). A few individuals were resident for up to four weeks; they then ‘disappeared’ for several months, and were recaptured

again at exactly the same place as previously. One individual resided for 25 months, including absences of 12 months and six months. Similar behaviour and nomadism has also been observed in Gabon.

Reproduction and Population Structure Pregnancies recorded in Mar and Jun, and young in Jan, Jun and Dec in W Nigeria (Happold 1977), and in Jan and in Apr–Sep inclusive in E DR Congo (Rahm 1970). Litter-size: 3 (n = 2; Happold 1987). Embryo number: 2.1 (1–4, n = 17, mode 2; DR Congo; U. Rahm in Delany 1975); 2.5 (1–4, mode 2; Gabon; Dubost 1968). The limited data suggest that Target Rats have small litters, breed during most months of the year and have the potential to live for a comparatively long period of time (cf. *Praomys tullbergi*, which lives syntopically with *S. longicaudatus* in Nigeria).

Predators, Parasites and Diseases In Dzanga-Sangha Forest Reserve, Central African Republic, *S. longicaudatus* comprised 6% of small rodent prey (WT: <100 g) of Long-nosed Mongooses *Herpestes naso* (n = 86 scats with small mammal remains), more than expected on the basis of trapping results. Similar data for all small carnivores is 4% (n = 251 scats). Small carnivores appear to prey selectively on this species (Ray 1998).

Conservation IUCN Category: Least Concern.

Target Rats are dependent on moist rainforest habitats, so their conservation is dependent on extensive areas of rainforest.

D. C. D. Happold

GENUS *Thallomys* Acacia Rats (Tree Rats)

Thallomys Thomas, 1920. Ann. Mag. Nat. Hist., ser. 9, 5: 141. Type species: *Mus nigricauda* Thomas, 1882.

The genus contains four species (Table 41) widely distributed in arid and savanna habitats in southern and eastern Africa. The genus is characterized by medium size, long brown or dark-coloured tail, dark facial markings (usually present), four digits on forefoot (Digit 1 absent or reduced to very small tubercle), relatively short hindfeet with five digits, Digit 1 much shorter than Digits 2–5. The skull is *Rattus*-like, with broad palate, long and wide anterior palatal foramina extending posteriorly to the first row of cusps of M¹, and moderately well-developed supraorbital ridges (Figure 88). The generic name is derived from the Greek *thallos* meaning a fine twig, and refers to the

fact that these rats feed on the young leaves and twigs of *Acacia* trees and use them for nest construction.

All species in the genus are arboreal – an unusual feature for murids, shared only with *Grammomys*, *Thamnomys* and *Hylomyscus*. Nocturnal; during the day individuals rest in nests built among the branches of trees, which they construct from cut twigs. The diet is vegetarian, primarily leaves and shoots of the trees where they live. The gastrointestinal tract exhibits some unusual characters not seen in most murid rodents. The stomach is unilocular and hemiglandular, and also has folds that channel the movement of

Thalomys paedulus.

foods, and parts have papillae that increase the surface area of the stomach. Some parts are cornified. The stomach contains bacteria that are presumed to assist in the breakdown and fermentation of food (Perrin 1986). The caecum is comparatively large (Perrin & Curtis 1980). These characters may be related to feeding almost exclusively on *Acacia* trees (see below). No other rodents has exploited this feeding niche, and hence competition with any other species is minimized.

The status and relationships of the genus are uncertain. Thomas (1920) separated this genus from *Rattus*, and Ellerman (1941) retained it as a separate genus. Ellerman *et al.* (1953) placed *Thalomys* with the subgenus *Aethomys* in the genus *Rattus*. Subsequent authors (De Graaff 1981, Smithers 1983, Musser & Carleton 1993, 2005) retain *Thalomys* as a valid genus. The number of species in the genus is also controversial. Misonne (1974) and De Graaff (1981) recognize one species, *T. paedulus*. Meester *et al.* (1986) also recognize one species, with 14 subspecies in the southern African region. Petter (1973) recognizes two species, *T. paedulus* and *T. damarensis*, as did Dippenaar *et al.* (1983) on the basis of karyotypes. Gordon (1987) found *T. paedulus sensu lato* to comprise two chromosomal species, *T. paedulus* ($2n = 43-47$) and *T. nigricauda* ($2n = 47-50$). The ranges

Figure 88. Skull and mandible of *Thalomys nigricauda* (BMNH 25.12.4.152).

of these two species appear to be parapatric, *T. paedulus* being associated with the Zambezian Woodland BZ and *T. nigricauda* with the South-West Arid BZ (Taylor 1998). Taylor *et al.* (1995) used discriminant analysis to derive craniometric criteria for the two chromosomal species and plotted revised distribution maps, which indicated a complicated pattern of widespread sympatry throughout southern Africa. The situation remains unclear and requires further biogeographic, karyotypic, morphometric and molecular studies to resolve species limits.

Four species are recognized here, and are distinguished by size (to limited extent), pelage colour, chromosome number and distribution.

Thallomys loringi LORING'S ACACIA RAT (LORING'S THALLOMYS)

Fr. Rat arboricole de Loring; Ger. Lorings Baumratte

Thallomys loringi (Heller, 1909). Smithsonian Misc. Coll. 52: 471. L. Naivasha, Kenya.

Taxonomy Originally described in the genus *Thamnomys*, but Thomas & Hinton (1923b) correctly transferred it to the genus *Thallomys*. Subsequently, most authors have considered *loringi* to warrant only subspecies recognition, either within *T. nigricauda* (Hollister 1919, Allen 1939, Ellerman, 1941) or *T. damarensis* (Petter 1973). Musser & Carleton (1993) reinstated *loringi* to species based on its distinctive morphology and viewed the form as most similar to (and probably phylogenetically closely allied with) *T. nigricauda*. No detailed evaluation of their degree of differentiation and level of relationship has yet been presented. Synonyms: none. Chromosome number: not known.

Description Medium- to large-sized rodent with prominent black facial markings and predominantly brown dorsally. Pelage medium-long (hairs 11–13 mm on rump), thick and soft. Dorsal pelage wood-brown, with blackish wash on middle back and rump; hairs pale plumbeous-grey on basal two-thirds, medium buff to pale ochraceous on distal one-third. Guard hairs dusky-brown. Ventral pelage creamy-white to whitish-grey; hairs pale grey at base, white or creamy-white distally. Flanks paler brown tending towards grey. Colour of ventral pelage sharply delineated from colour of flanks. Head brownish-grey; blackish-brown around eyes and side of muzzle forming a dark facial mask. Ears medium in length, with black epidermis and clothed externally and internally with ochraceous hairs. Upper surfaces of fore- and hindfeet with dull white hairs. Hindfoot relatively short and broad, Digit 5 nearly as long as Digits 2, 3 and 4, and much longer than Digit 1; plantar pads six, large and set close to one another. Tail long (ca. 110% of HB), dark all around, brown at base and becoming black toward tip; hairs black, short and inconspicuous over proximal two-thirds of tail, longer over distal third and forming a weak pencil. Skull large for the genus, with laterally bowed zygomatic arches and narrow interorbital constriction. Supraorbital ridging weakly developed, in adults forming an obtuse projection at rear of orbit. Anterior palatal foramina relatively short, terminating posteriorly in front of or in line with anterior root of M¹; bony palate correspondingly long. Auditory bullae large. Nipples: 0 + 2 = 4.

Geographic Variation None recorded.

Similar Species

T. paedulus. Dorsal pelage exhibiting more grey, especially over the head, forequarters and flanks; ventral pelage pure white, hairs white to base; tail blacker throughout length, hence more noticeably contrasting with dorsal pelage; anterior palatal foramina longer, terminating posteriorly between M¹'s, bony palate correspondingly shorter. Possibly sympatric with *T. loringi* in W Kenya or N Tanzania.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from the Gregorian Rift Valley in W, C and SW Kenya and extreme N Tanzania; limits of geographic range uncertain. Known altitudinal range ca. 1000–2300 m.

*Thallomys loringi*

Habitat *Acacia* trees, shrubby woodlands and brushy thickets in East African savanna. Specimens have been obtained in traps placed 'on limb of acacia,' 'near hole at base of thorn tree in shrubby area,' 'at base of thorn tree in grassy area with scattered trees and shrubs,' and in 'runway in thick growth of weedy herbs' (habitat notes, USNM field labels).

Abundance No information.

Adaptations Nocturnal. Trapping results indicate both arboreal and terrestrial activity and well-developed scansorial abilities (Heller 1910 [in Roosevelt 1910], Loring 1910 [in Roosevelt 1910]). The natural history of *T. loringi* is very poorly documented, but anecdotal observations by collectors suggest that its ecology, food habits, behaviour and reproduction may generally resemble *T. nigricauda* and *T. paedulus*, the better known species in southern Africa.

Foraging and Food No information.

Social and Reproductive Behaviour Nests in branches of thorn trees or bushes, perhaps also in burrows near the base of trees; arboreal nests about 16 cm in diameter, fashioned of sticks, leaves and grasses (Heller 1910, Loring 1910 [both in Roosevelt 1910]). Heller (1910 [in Roosevelt 1910]) noted that runways lead from trees that contained active nests to ground burrows.

Reproduction and Population Structure Four embryos recorded for a ♀ (collected in Apr) from the Loita Plains, Kenya.

Predators, Parasites, and Diseases No information.

Conservation IUCN Category: Least Concern.

Thallomys nigricauda BLACK-TAILED ACACIA RAT (BLACK-TAILED THALLOMYS)

Fr. Rat arboricole à queue noire; Ger. Schwarزشwänzige Baumratte

Thallomys nigricauda (Thomas, 1882). Proc. Zool. Soc. Lond. 1882: 266. Hountop (= Hudup or Hutop) River, west of Gibeon, Namibia.

Taxonomy Originally described as *Mus nigricauda*, but later assigned to the newly described genus *Thallomys* by Thomas (1920). Misonne (1974), De Graaff (1981), Smithers (1983) and Meester *et al.* (1986) refer to *nigricauda* as a subspecies of *T. paedulus*. Currently recognized as a valid species because of differences in chromosome number, body size and geographical distribution compared with *T. paedulus* (Gordon 1987). Geographical variation in external characters resulted in descriptions of 13 subspecies (see Meester *et al.* 1986), all now regarded as synonyms. Synonyms: *bradfieldi*, *damarensis*, *davisi*, *kalaharicus*, *molopensis*, *nitela*, *quissamae*, *robertsi* (two other forms, *herero* and *leuconoe* may represent *T. paedulus*). Subspecies: uncertain. Chromosome number: 2n = 47–50 (Gordon 1987).

Description Medium-sized rodent with soft, woolly pelage. Hairs long (15 mm on mid-back, 17 mm on rump). Dorsal pelage slate-grey with a wash of yellow; hairs pale slate-grey, yellow at tip, with liberal sprinkling of longer black hairs. Flanks pale grey. Ventral pelage, including chin and throat, white. Sides of face pale grey. Black band extends from nose to around eyes, and in some individuals tapers to below ears (indistinct in some populations). Long vibrissae and large eyes. Ears large, oval, especially prominent in juveniles, set at angle to head. Upper parts of legs pale grey. Feet short, broad, with strong claws and white upper parts. Four digits on forefeet. Five digits on hindfeet; Digit 5 elongated, almost as long as Digit 2. Tail long (ca. 120% HB), with black scales and short bristly black hairs; tip with longer black hairs. Nipples: 1 + 2 = 6.

Geographic Variation Until the degree of similarity or difference between the external characters of *T. nigricauda* and *T. paedulus* is resolved, as well as their geographical relationship (see Taylor *et al.* 1995), no comments on geographical variation in *T. nigricauda* are possible.

Similar Species

T. paedulus. External differences still unresolved (Taylor *et al.* 1995).

Whereas Gordon (1987) found allopatry between the two species, Taylor *et al.* (1995) suggest extensive overlap in distribution. Chromosome number: 2n = 43–46.

T. shortridgei. Similar body size; tail longer, less hairy; dorsal pelage brown (not grey); ventral pelage slatey-grey at base; feet longer;

Thallomys nigricauda

marked reduction in black facial markings; skull on average slightly larger; nipples 0 + 2 = 4; chromosome number not known.

Distribution Endemic to Africa. South-West Arid BZ (particularly Kalahari Desert). Recorded in Namibia (except Namib Desert and dwarf shrublands), Botswana (except NE), NW South Africa and marginally in SW Angola. Degree of allopatry with *T. shortridgei* unknown (Thomas & Hinton 1923b, Taylor *et al.* 1995).

Habitat Arid savanna, especially Kalahari thornveld with *Acacia erioloba*, *A. luederitzii*, *Boscia albitrunca* and *Terminalia sericea* trees and *A. mellifera* shrubs. Also lives in habitats with *A. karoo* (interior plateau of Namibia) and *Euclea pseudobenus* (Naukluft Mts). Occurs mostly in dense or open stands of trees, but also in large isolated trees ca. 150 m away from stands.

Abundance Common in stands of suitable trees, especially *A. erioloba*, which contains cracks or nesting hollows in the trunks or between branches. Localized reduction of population numbers occurs in the SW Kalahari, perhaps due to smoke from bushfires filtering through nests and crevices. The number of inhabited trees in unburnt and burned areas differs significantly, even where many trees are only singed by the fire in 'burned' areas (J. A. J. Nel unpubl.). Single individuals, or (presumed family groups) of 2–8 inhabit specific trees (Lovegrove 1997).

Adaptations Nocturnal and arboreal. Black-tailed Acacia Rats are agile climbers; they use the prehensile tail for balancing, and the strong claws and broad feet for climbing. They construct conspicuous nests in hollow trunks and forks of trees; in the SW Kalahari, nests are 20–50 cm in diameter and there may be 1–3 nests per tree. Not all nests are occupied. Along one stretch of dry river bed, 50% of *Acacia erioloba* trees (n = 50) were inhabited. Larger trees with a circumference of 2.3 m are inhabited to a greater extent (44%) than smaller trees with a circumference of 1.7 m (15%). No correlation exists between tree size and number of nests. However, 80% of trees with signs of use (presence of faeces) by these acacia rats had no visible nests (J. A. J. Nel unpubl.). Untidy piles of interlaced twigs and thorns may hinder predators trying to enter the nest or the crevice in the tree trunk or branch. Nests are larger and better constructed than those of *T. paedulus* (Roberts 1951, Van Huyssteen 1978), but only buffer ambient temperatures by a few degrees (Lovegrove *et al.* 1991). Evaporative cooling helps to maintain body temperature well below ambient temperatures up to $T_a = 42^\circ\text{C}$, and conserves energy during the day by dropping body temperature by about 3°C (Lovegrove *et al.* 1991, Lovegrove 1997). Mean T_b is 38.2°C for males (n = 2) and 38.8°C for females (n = 6) (Nel & Rautenbach 1977). Black-tailed Acacia Rats can subsist on a vegetarian diet without free water, and their kidneys have a high urine concentrating ability (Frean *et al.* 1998).

Foraging and Food Emerges from the nest and starts to forage at dusk. Active throughout the night, with a peak of activity in the early evening that lasts longer (19:00–22:00h) in the breeding season than in the non-breeding season (19:00–21:00h) (Eccard *et al.* 2004); during the breeding season, a second peak of activity occurs near the end of the night (04:00–07:00h). These acacia rats forage in the upper levels of tree canopies, where there are no other rodent competitors, and in *Acacia* shrubs (Eccard *et al.* 2004). Foraging seldom occurs on the ground. The diet comprises young leaves, buds, the outer tunic of *Acacia* seed pods and gum obtained from grooves that the rats make by gnawing into the branches and trunks of *Acacia* trees. Occasionally, insects are eaten.

Social and Reproductive Behaviour Lives in groups of 2–8 in a single tree; groups probably consist of a breeding pair and one or more litters (Lovegrove 1997). Branches are marked by perineal dragging (Earl & Nel 1976). Single, large isolated trees or stands of trees with interlacing branches probably constitute the home-range of an individual. During the breeding season, home-ranges of ♂♂, assessed by the minimum convex polygon method, are larger (5.9–

11.5 ha, n = 3) than those of ♀♀ (0.02–0.17 ha, n = 3). In the non-breeding season, the home-ranges of ♂♂ are smaller (1.9 and 3.2 ha, n = 2) but still larger than those of ♀♀ (0.1–0.5 ha, n = 4). Males also have larger core areas than ♀♀. Females always use two core areas: one at the nest and one at a preferred feeding site (Eccard *et al.* 2004). The home-range of a ♂ usually overlaps with those of one or more ♀♀, but the core areas do not overlap (Eccard *et al.* 2004). Several social structures have been described: a breeding pair per nest with their offspring of different ages (De Graaff 1981); a family of related individuals (Roberts 1951) and a colony (Nel 1975). By following individuals with radio transmitters, Eccard *et al.* (2004) found that these acacia rats lived solitarily or with their offspring, and that they had a promiscuous breeding system. It may be that social structure varies according to the habitat.

Reproduction and Population Structure Births occur from Oct to Apr. Litter-size: 3.6 (2–5) (Skinner & Smithers 1990). Young nipple-cling (aided by prominent notches in the deciduous upper incisors) and can be carried in this way by the mother when moving to a new nest (J. A. J. Nel unpubl.) or when escaping predators (Lovegrove 1997), but not when foraging. Hair begins to grow on Day 3, pelage is completely developed at Day 9 when the tail starts getting darker and the eye-rings become noticeable. Climbing begins at Day 17 and is proficient at Day 19 (Van Huyssteen 1978). Weaned at Day 33.

Predators, Parasites and Diseases Predators include snakes, e.g. Cape Cobras *Naja nivea*, and owls to a small extent. Ectoparasites recorded for *Thallomys paedulus sensu lato* (i.e. including *T. nigricauda*) include fleas of the families Pulicidae, Hystrihopsyllidae and Chimaeropsyllidae (including some spp. that are vectors of plague), mites and ticks (details in De Graaff 1981). One endoparasite, a cestode *Inermicapsifer madagascariensi*, has been recorded (De Graaff 1981).

Conservation IUCN Category: Least Concern.

Thallomys paedulus SUNDEVALL'S ACACIA RAT (ACACIA THALLOMYS)

Fr. Rat arboricole des Acacias; Ger. Sundevalls Baumratte

Thallomys paedulus (Sundevall, 1846). Ofv. K. Svenska Vet.-Akad. Forhandl. Stockholm, 3: 120. 'In Caffrania interiore, prope tropicum'. Davis (1965) defines the type locality as Crocodile Drift, Brits, Transvaal, South Africa.

Taxonomy Originally described in the genus *Mus*. The limits of this species have been controversial, and there have been many changes in the definition of the species. De Graaff (1981) and Smithers (1983) considered that *T. paedulus* was the only species in southern Africa. Meester *et al.* (1986) likewise recognized only *T. paedulus*, and listed 14 forms as subspecies in southern Africa. Smithers (1971) listed three subspecies in Botswana, and Smithers & Wilson (1979) listed two subspecies in Zimbabwe. Two of these forms are now considered to be valid species (*T. nigricauda*, *T. shortridgei*), the remainder are regarded as synonyms of this species or of *T. nigricauda* (see De Graaff 1981 and Meester *et al.* 1986 for detailed reviews). Because *T. nigricauda* was included in *T. paedulus* until recently, some of the biological information for *T. paedulus* in southern Africa may refer to *T. nigricauda*. Synonyms: *acaciae*, *lebomboensis*, *moggi*, *rhodesiae*, *ruddi*, *scotti*, *somaliensis*, *stevensoni*, *zambeziensis*. Subspecies: none. Chromosome numbers: $2n = 43, 44, 45$ and 46 ; species-specific X chromosome (Gordon & Rautenbach 1980, Bowland & Gordon 1983, Gordon 1987).

Description Medium-sized arboreal mouse with very long black or blackish-brown tail. Pelage generally long and soft. Dorsal pelage yellowish-grey, pale rufous, cinnamon or pale brown; dorsal hairs medium-grey at base, with buff, cinnamon or yellowish-brown at tip; scattered fine black guard hairs. Flanks often greyer than dorsal pelage. Ventral pelage pure white. Pelage colour varies geographically and seasonally (see below). Head similar in colour to dorsal pelage. Black markings on face extend from nose to the eye, around each eye and more diffusely to the ear in some individuals. Eyes large and black. Ears conspicuous, rounded, pigmented, with sparse buff hairs. Chin and throat pure white. Limbs short. Upper surface of forefeet and hindfeet with dense, short, white hair, and strong, short claws. Tail long (ca. 120% of HB), black or blackish-brown, scaly, with numerous small black bristles. Skull: auditory bullae unusually large for a murid rodent (ca. 6 mm); anterior palatal foramina long, extending posteriorly to between M^1 's (cf. *P. loringi*). Nipples: $0 + 3 = 6$, $0 + 2 = 4$, $1 + 2 = 6$.

Geographic Variation Pelage colour varies geographically. In Botswana, for example, pelage is grey with a yellow tinge in drier habitats (Kalahari), and buffy-brown with darker flanks in moister habitats (Okavango Delta) (Smithers 1971). In Zimbabwe, some individuals have brown forefeet rather than white forefeet (Smithers & Wilson 1979). In Kenya, dorsal pelage tends to be pale rufous or cinnamon. Length of M^1 – M^3 varies geographically, but the significance of this variation is uncertain. Pelage varies seasonally in Botswana: in Nov–Apr (warm wet season), pelage is shorter, darker and less dense than in Jun–Oct (cool dry season) when it is longer, paler (yellow or reddish) and denser (Smithers 1971).

Similar Species

T. nigricauda. Similar in size; black markings on head more conspicuous; tail black; may be parapatric in Botswana.

T. loringi. Similar size; dorsal pelage brown (not grey); possibly sympatric in Kenya and Tanzania.

Graphiurus spp. Smaller; bushy tails.

Distribution Endemic to Africa. Zambezi Woodland BZ and southern part of Somalia–Masai BZ. Recorded from E South Africa (Transvaal and KwaZulu–Natal Provinces), Angola, Botswana, Zimbabwe, Mozambique (south of the Zambezi R.), Swaziland, S Zambia, S DR Congo, Malawi, Tanzania, Kenya, S Ethiopia and S Somalia. Limits uncertain. Widespread in southern Africa; localized in East Africa.

Habitat Savanna habitats, especially woodlands of *Acacia* spp. In East Africa, associated mainly with *A. xanthophloea* and *A. tortilis* trees (Kingdon 1974).

Abundance Locally common in suitable habitats but populations may be small and isolated; no quantitative information available.

Adaptations Arboreal and nocturnal. Lives more or less continuously in trees and is well adapted for arboreal life. In Zimbabwe, makes nests of grass, sticks and leaves, which are dragged into hollow trunks or under the bark of trees (Smithers & Wilson 1979). Probably independent of free drinking water. In most respects, these acacia rats appear to resemble *T. nigricauda*. See also genus profile.

Thallomys paedulus has a complex sacculated stomach comprising a non-glandular forestomach with diverticulae (pouches) that

*Thallomys paedulus*

contain symbiotic bacteria, a glandular stomach and also complex folds and sphincters that control regurgitation and the passage of the digesta (flow of the food) (Perrin 1986). The stomach is one of the most complex described for any rodent. Its function is aided by the microflora, which are thought to detoxify chemical plant defences as well as digest complex polysaccharides.

Foraging and Food Predominantly vegetarian. Most food is obtained in trees. Forages mainly in the canopy, and has regular pathways along the lower branches. The principal food is fresh young leaflets and green twigs of *Acacia* trees and, less frequently, *Acacia* flowers, the green or outer coating of *Acacia* pods and the berries of *Zizyphus macronata* (Smithers & Wilson 1979). At times, may forage on the ground for *Acacia* pods.

Social and Reproductive Behaviour Little information; acacia rats probably live in small communities of an adult pair and their offspring (De Graaff 1981).

Reproduction and Population Structure In Zimbabwe, pregnant ♀♀ recorded in Aug, Nov, Feb (four pregnancies in sample of 23, taken throughout year) (Smithers & Wilson 1979). In Botswana, pregnant ♀♀ recorded in Oct, Feb, Mar and Apr (five pregnancies in sample of 93, taken throughout year). In southern Africa, most pregnancies recorded in the warmer months of the year; no information for eastern Africa. Reproductive data for captive individuals (originally from Transvaal) kept at ambient temperatures (Meester & Hallett 1970) are: litter-size: 2.7 (range not given; $n = 23$ litters); minimum interval between litters: 26 days. At birth, WT: 2.5–2.8 g, altricial and hairless. Incisors erupt Day 1; ear pinna open Day 1; eyes open

Day 15; efficient walking Day 15; weaned Day 28–31; minimum age at maturity (age at first litter) Day 107. Young attached to nipples until Day 25; mother nipple-draws until Day 15.

Predators, Parasites and Diseases Predators include the Giant Eagle-owl *Bubo lacteus* (Pitman & Adamson 1978). Ectoparasites include many species of fleas and mites, and are probably similar to those of *T. nigricauda* (details in De Graaff 1981). Host to the flea *Xenopsylla brasiliensis*, which is a vector of plague (De Meillon *et al.* 1961).

Conservation IUCN Category: Least Concern.

Thallomys shortridgei SHORTRIDGE'S ACACIA RAT (SHORTRIDGE'S THALLOMYS)

Fr. Rat arboricole de Shortridge; Ger. Shortridges Baumratte

Thallomys shortridgei Thomas & Hinton, 1923. Proc. Zool. Soc. Lond. 1923: 492. Louisvale on the south bank of the Gariep (= Orange) River, near Upington, Northern Cape Province, South Africa.

Taxonomy Described by Thomas & Hinton (1923) as a distinct species on the basis of external and skull characters, especially the weakly developed facial markings and smaller auditory bullae. This view was accepted by Roberts (1951), who recognized four species of *Thallomys* in southern Africa: *T. nigricauda*, *T. shortridgei*, *T. damarensis* (now synonym of *T. nigricauda*) and *T. moggi* (now synonym of *T. paedulus*). However, Ellerman (1941) regarded *shortridgei* as a subspecies of *Thallomys nigricauda*. More recent assessments have maintained *shortridgei* as a valid species (Skinner & Smithers 1990, Musser & Carleton 1993, 2005, Bronner *et al.* 2003). Synonyms: none. Chromosome number: not known.

Description 'A brown species with slightly developed face markings. Size about as in *T. nigricauda*, or slightly smaller. General colour above brown – near "Brussels Brown" – not as greyish as in other species. Under surface white, but the bases of the hairs are mostly slaty ... Face grey, but the brown of the crown reaches as far forward as between the eyes. Dark facial markings hardly developed at all, the darker edges of the orbit quite narrow and inconspicuous, and not

extending forwards or backwards as an ocular streak. Ears about the colour of the head; hairs behind them buffy-brown. Hands and feet white, with darker patches on the metapodials. Tail long, black. ... Skull with well-marked supraorbital ridges, long anterior palatal foramina, and rather small bullae ...' (Thomas & Hinton 1923b). Nipples: 0 + 2 = 4.

Geographic Variation None recorded.

Similar Species

T. nigricauda. Grey above (not brown), black facial markings much more prominent, tail more haired, shorter; ears slightly smaller; auditory bullae slightly larger. Nipples: 1 + 2 = 6.

Distribution Endemic to Africa. South-West Arid BZ. Recorded only in South Africa, from the south bank of the Gariep (= Orange) River, from near Upington westwards to Goodhouse. Degree of allopatry with *T. nigricauda* not known.

Habitat *Acacia* thornveld and scrub.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Data Deficient.

GENUS *Thamnomys*

Thicket Rats

Thamnomys Thomas, 1907. Ann. Mag. Nat. Hist., ser. 7, 19: 121. Type species: *Thamnomys venustus* Thomas, 1907.

The genus *Thamnomys* contains three species, each with a very restricted distribution in the Rainforest BZ of DR Congo, or in the montane forests of the Albertine Rift Valley. The genus is not well known because of its restricted distribution and rarity.

All species in the genus are medium-sized with soft long pelage and a very long tail ending in a small pencil. Dorsal pelage is brownish, usually orange-rufous on the rump, and ventral pelage is whitish. Hindfeet are broad and relatively short. The cheekteeth are distinguished by the strongly developed postero-internal cusp (t7) on M¹ and M²; in this respect, it differs from the closely related genus *Grammomys* in which the cusp is reduced to a narrow ridge between t4 and t8 (see genus profile). This difference is considered to be large enough to warrant generic recognition (Ellerman 1941, Rosevear 1969, Hutterer & Dieterlen 1984, Musser & Carleton 1993). The almost rectangular-shaped molars of *Thamnomys* are in contrast to the rounded shape of the upper molars of *Grammomys*. The skull has a long rostrum, broad braincase, well-developed supraorbital ridges, long open anterior palatal foramina, which reach nearly to the level of M¹, medium-sized auditory bullae, and the zygomatic plate is more or less straight anteriorly (Figure 89). The molar pattern shows great similarities to that of the genus *Oenomys*.

All species in the genus are arboreal and, like *Grammomys* spp., show adaptations for climbing on branches and twigs. Collectively, less is known about the biology of *Thamnomys* spp. than for *Grammomys* spp., although it is presumed that both genera are rather similar in many respects (see *Grammomys* profiles). All species of *Thamnomys* are

Thamnomys venustus.

Figure 89. Skull and mandible of *Thamnomys venustus* (BMNH 65.3777).

Thamnomys kemp KEMP'S THICKET RAT (KEMP'S THAMNOMYS)

Fr. Rat des fourrés de Kemp; Ger. Kemps Dickichtratte

Thamnomys kemp Dollman, 1911. Ann. Mag. Nat. Hist., ser. 8, 8: 658. Buhamba, near L. Kivu, DR Congo. 6000 ft (1830 m).

Taxonomy Although described as markedly different from *Thamnomys venustus*, *T. kemp* was often considered to be a subspecies of *T. venustus* (e.g. Ellerman 1941, Misonne 1974). Important differences in skull characters, especially larger size, longer anterior palatal foramina than in the other species, and the absence of t9 on M¹ and M², justify recognition of *T. kemp* as a valid species. *Thamnomys kemp* may represent a subgenus, separate from *T. venustus* and *T. schoutedeni* (Dieterlen 1999 and unpubl.). Synonyms: *major*. Subspecies: none recognized here, although *major* was considered to be a subspecies by Musser & Carleton (1993) and a distinct species by Musser & Carleton (2005). Chromosome number: not known.

Description Large arboreal rat with bright orange-rufous pelage and very long tail; the largest species of the genus. Dorsal pelage soft and long (ca. 15 mm), bright orange-rufous especially on rump; hairs black at base, rufous at tip; brown hairs interspersed in pelage, especially on anterior part of body. Flanks slate-grey, washed with bright yellowish-buff. Ventral pelage whitish, often with yellowish or yellowish-orange tint; hairs dark at base, whitish at tip. Colour of flanks clearly delineated from ventral pelage, sometimes with thin line of yellow. Head greyish-buff; tip of nose black. Narrow dark eye-ring. Ears with dark brownish hairs on outer surface and short golden-buff hairs on inner surface. No subauricular tuft. Hindfeet broad and comparatively short. Fore- and hindlimbs and fore- and hindfeet buff, with conspicuous dark patches on upper surfaces of feet. Tail very long (ca. 130% of HB), slightly scaly, dark above, slightly paler below, with short bristles, and longer hairs at tip

probably vegetarian, and limited evidence suggests that they have small litters. The genus has a very limited distribution compared with *Grammomys*, and each species within the genus has a much smaller distribution than most species of *Grammomys*.

Phylogenetically *Thamnomys* is close to *Oenomys*. The genus *Thamnomys* at one time contained all those species now assigned to the genus *Grammomys*, or to the subgenus *Thamnomys* (*Grammomys*); hence *Thamnomys* now contains fewer species than previously.

The species in the genus may be distinguished by body size (see species profiles).

Fritz Dieterlen

forming pencil. In young individuals, dorsal pelage dark brownish-grey, ventral pelage whitish (but less so than in adults), sometimes with orange tint. Skull with long anterior palatal foramina (mean 8.80 mm); t7 on M¹ and on M² elongated and well developed; t9 on M¹ and on M² absent. Nipples: 0 + 2 = 4.

Geographic Variation Two forms may be distinguished:

kemp: Virunga Mts southwards on both sides of the Albertine Rift Valley to ca. 02° 20' S. Characters as described above.

major: Virunga Mts above 3000 m (parts only). Pelage longer; skull measurements on average longer than in *kemp*.

Similar Species

T. venustus. On average smaller than *T. kemp*; skull smaller, anterior palatal foramina shorter (mean 6.50 mm), molar teeth smaller and narrower; large t9 on M¹ and smaller t9 on M²; partially sympatric.

T. schoutedeni. Smallest species of genus (means: HB: 119 mm, HF: 25 mm); skull smaller; anterior palatal foramina shorter (mean 6.81 mm); large t9 on M¹; not sympatric.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of the Albertine Rift Valley on both sides of L. Kivu. Recorded from a relatively small area between ca. 01° S and 03° S; known from the Virunga Mts and Kahuzi–Biega N. P. west of L. Kivu in DR Congo, Nyungwe F. R. in Rwanda, and from NW Burundi. The presence of

Thamnomys kempi

T. kempi from north of the Virunga Mts to the highlands west of L. Albert is uncertain (because of the problems of identification and separation from *T. venustus*). Altitudinal range ca. 1800–3500+ m.

Habitat Preferred habitat is thickets in open areas of montane secondary forests (and occasionally in primary forests) (F. Dieterlen unpubl.). The thickets are composed mainly of two vines *Sericostachys scandens* and *Urera hypselodendron*, a herb *Brillantaisia cicatricose*, and a tree fern *Marattia fraxinea*; the forest includes *Neobutonia macrocalyx*, *Hagenia abyssinica* and *Myrianthus holstii* trees. Not recorded from bamboo forests or marshes near to thickets.

Abundance Generally rare; in four regions of E DR Congo, comprised 2.5% (1.6–13.5%) of all small rodents obtained (regardless of habitat; $n = 5883$). Occasionally may be quite common in suitable thickets; in one thicket comprised 39% ($n = 40$) of small rodents. More common than the other species of *Thamnomys*.

Adaptations Kemp's Thicket Rats are good climbers, which live most of the time in thickets, although they may also descend to the ground. They build large nests. Activity is chiefly nocturnal and crepuscular (ca. 60%; Rahm 1967). Morphological adaptations for climbing include short broad hindfeet and long tail. The alimentary tract is unusually long, six times longer than HB length, indicating

a pure vegetarian diet. Stomachs are large and when full weigh up to 22% of body weight. Length and volume of caecum and colon are also large and typical of a herbivore. Measurements (means and ranges for freshly caught specimens): stomach 52 (45–60) mm; small intestine 450 (380–480) mm; caecum 97 (85–115) mm; colon 340 (290–380) mm (F. Dieterlen unpubl.).

Foraging and Food Herbivorous. The diet appears to be almost exclusively green material. Stomach contents consisted of a uniform green pulp with only very small fibres, sometimes with fruit pulp. Since herbs were not abundant near thickets, the 'green pulp' is assumed to be from leaves, buds and fruits of thicket plants. An individual in captivity preferred fruits (bananas etc.) (F. Dieterlen unpubl.).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Reproduction recorded in all months from Jan to Sep, when 70–100% (mean 72%) of 47 adult ♀♀ were pregnant and/or lactating; reproduction lower in Oct–Dec (mean 30%, $n = 10$) (F. Dieterlen unpubl.). Embryo number: 1.43 (1–2), $n = 23$ ♀♀. Young are born in nests, and nipple-cling even when mother is active outside the nest (Hatt 1940a). Sexual maturity attained when 70 g. Sex ratio of trapped individuals: 61% ♀♀ : 39% ♂♂ ($n = 161$ captures); ratio more biased towards ♀♀ than in other murids in central Africa.

Conservation IUCN Category: Vulnerable.

Montane forests along the Albertine Rift Valley are under threat, and hence the species should be considered as vulnerable or endangered (as are other endemic species in the Albertine Rift Valley).

Thamnomys schoutedeni SCHOUTEDEN'S THICKET RAT (SCHOUTEDEN'S THALLOMYS)

Fr. Rat des fourrés de Schouteden; Ger. Schoutedens Dickichtratte

Thamnomys schoutedeni Hatt, 1934. Amer. Mus. Novit. 708: 9. Medje, Ituri District, DR Congo.

Taxonomy The form *schoutedeni* was first described as a subspecies of *Thamnomys venustus* by Hatt (1934). Raised to specific rank by Dieterlen (1999) on the basis of its smaller body and skull measurements.

Musser & Carleton (2005) place *schoutedeni* as a synonym of *T. venustus*. Synonyms: none. Chromosome numbers: not known.

Description Small to medium-sized arboreal rodent; smallest species in the genus. Pelage long and soft. Dorsal pelage brown or russet-brown; hairs grey at base, brownish at tip. Flanks paler. Ventral pelage whitish; hairs grey at base, white at tip; colour of base shows on surface of pelage. Colour of flanks clearly delineated from ventral pelage, without any separating line of colour. Head similar in colour to dorsal pelage. No dark eye-ring. Ears dark brownish. White subauricular tuft. Hindfeet comparatively short. Upper surface of feet similar in colour to flanks. Tail very long (ca. 155% of HB), brown, almost naked, with slight pencil at tip. Skull with relatively long anterior palatal foramina (mean 6.81 mm); t7 on M¹ and on M² elongated and well developed; large t9 on M¹ and smaller t9 on M². Nipples: not known.

Geographic Variation None recorded.

Similar Species

T. kempi. Much larger in all measurements; skull with longer anterior palatal foramina (mean 8.80 mm); t9 on M¹ and on M² absent.

T. venustus. Larger in all measurements; skull larger, anterior palatal foramina shorter (mean 6.50 mm), large t9 on M¹.

Grammomys kuru. Similar in size (perhaps very slightly smaller); pelage shorter, ventral pelage pure white, molars with rounded shape, t7 and t9 of M¹ and M² smaller.

Distribution Endemic to Africa. Rainforest BZ (East Central Region). Recorded only at Medje (800 m) in Ituri Forest, DR Congo, and at Irangi, E DR Congo (ca. 800–1450 m).

Habitat At Irangi, primary rainforest, secondary forest and submontane forest.

Abundance Extremely rare, known only by a few specimens. Appears to be much rarer than *G. kuru*, with which it is syntopic.

Remarks Nothing is known about this species, but it is assumed that it has a similar life-style to other species in the genus, and to *G. kuru*.

Conservation IUCN Category: Data Deficient.

Thamnomys venustus CHARMING THICKET RAT (THOMAS'S THAMNOMYS)

Fr. Rat des fourrés charmant; Ger. Anmutige Dickichtratte

Thamnomys venustus Thomas, 1907. Ann. Mag. Nat. Hist., ser. 7, 19: 122. Rwenzori East, Uganda. 7000 ft (2130 m).

Taxonomy Type species of the genus *Thamnomys*. Specimens recorded as *T. venustus* from parts of Uganda and DR Congo (see below) may not be this species and hence biological information from these specimens is not included here. Synonyms: *kivuensis*. Subspecies: the form *kivuensis* was considered to be a subspecies by Allen & Loveridge (1942) but it is not recognized as such here. Chromosome number: not known.

Description Medium-sized arboreal species with a very long tail; rather similar to *T. kempi* but smaller, although larger than *T. schoutedeni*. Dorsal pelage long (ca. 15 mm), dark brown; hairs slate-grey at base,

reddish-brown or yellowish-brown at tip. Flanks yellowish-brown; hairs with bright yellow tip. Ventral pelage whitish, sometimes tinted with yellow; hairs greyish at base, whitish at tip; colour of base shows on surface of pelage. Colour of flanks clearly delineated from ventral pelage, sometimes with thin line of yellow. Head similar in colour to dorsal pelage. Narrow dark eye-ring. Ears reddish-brown. No subauricular tuft. Fore- and hindlimbs as well as fore- and hindfeet reddish-brown; toes whitish. Dark patches on upper surface of feet (as in *T. kempi*). Hindfeet broad and comparatively short. Tail very long (ca. 135% of HB), dark above, slightly paler below, with short hairs, longer hairs form a pencil at tip. Skull large with relatively

long anterior palatal foramina (mean 6.50 mm), but shorter than in *T. kemp*i); t9 on M¹ and on M² elongated and well developed; large t9 on M¹ and a smaller t9 on M². Nipples: 0 + 2 = 4.

Geographic Variation None recognized here.

Similar Species

*T. kemp*i. On average larger in most respects; skull larger; anterior palatal foramina longer (mean 8.80 mm); t9 on M¹ and M² absent. *T. schoutedeni*. Smaller in all respects, anterior palatal foramina longer (mean 6.81 mm); t9 on M¹ large.

Distribution Endemic to Africa. Afroalpine–Afroalpine BZ of the Albertine Rift Valley in a comparatively small area between ca. 01° N and 03° S. Recorded from East Rwenzori, Uganda; Kahuzi–Biega N. P., DR Congo (Dieterlen 1999); and on Idjwi I. in L. Kivu, DR Congo (Allen & Loveridge 1942). The identification of other specimens, purported to be *T. venustus*, from west of L. Albert (Blukwa, Djugu) and from the Lubero–Butembo highlands (both in DR Congo; Misonne 1963), Kigezi (Uganda; Delany 1975) and from the Virunga Mts (Verschuren *et al.* 1983) is uncertain. Altitudinal range ca. 1800–3000 m.

Habitat Thickets in montane forests; habitats similar to those of *T. kemp*i.

Abundance Uncertain; rarely collected.

Remarks Very little is known about the species, but it is probably similar in many ways to *T. kemp*i. Of two ♀♀ captured in the region of Kahuzi–Biega N. P. in Jun and Jul, one contained one embryo, the other was lactating.

Conservation IUCN Category: Vulnerable.

Montane forests along the Albertine Rift Valley are under threat, and hence the species should be considered as vulnerable or endangered (as are other endemic species in the Albertine Rift Valley). Recorded by Schlitter (1989) as ‘insufficiently known’ to place in any threat category.

GENUS *Zelotomys* Broad-headed Mice

Zelotomys Osgood, 1910. Field Mus. Nat. Hist. Publ. Zool. ser. 10 (2): 7. Type species: *Mus hildegardae* Thomas, 1902.

The genus contains two species, one (*Z. hildegardae*) in grasslands of the Zambezian Woodland BZ of central and eastern Africa, and the other (*Z. woosnami*) in arid and semi-arid habitats of the South-West Arid BZ of southern Africa.

The genus is characterized by its medium size, scaly white tail, ten nipples in ♀♀ of both species, and a superficial similarity to *Mastomys*. The skull is short and broad with very short braincase, ungrooved incisors, which are either pro-odont (*Z. hildegardae*) or orthodont (*Z. woosnami*), and very broad molars with rather high-crowned cusps (Figure 90). M¹ longer than M² + M³, and M² broader than long.

Zelotomys shows relationships to *Colomys* in respect of the molar teeth (Misonne 1969a), mitochondrial DNA cytochrome *b* (Lecompte *et al.* 2002b) and nuclear IRBP gene sequences (E. Lecompte, in Musser & Carleton 2005). *Zelotomys*, *Colomys* and *Myomyscus* appear to form a monophyletic cluster within a larger group composed of *Praomys*, *Mastomys*, *Myomyscus*, *Hylomyscus*, *Heimyscus* and *Stenocephalemys* (Musser & Carleton 2005).

Zelotomys is a rare or uncommon genus, and forms only a small percentage of rodent communities. Individuals of both species appear to be insectivorous or omnivorous, and mostly solitary. One species, *Z. hildegardae*, is noted for its very strong, offensive odour. Because

of their rarity, information on the genus is sparse. The species are distinguished by the form of the incisors and geographic distribution.

Jan A. J. Nel

Zelotomys hildegardae.

Figure 90. Skull and mandible of *Zelotomys hildegardae* (RMCA 82.11.M.531).

***Zelotomys hildegardae* HILDEGARDE'S BROAD-HEADED MOUSE (HILDEGARDE'S ZELOTOMYS)**

Fr. Souris de Hildegarde; Ger. Hildegardes Breitkopfmaus

Zelotomys hildegardae (Thomas, 1902). Ann. Mag. Nat. Hist., ser. 7, 9: 219. Machakos, Kenya.

Taxonomy Originally described in the genus *Mus*. Synonyms: *instans*, *kuvelaiensis*, *lillyana*, *shortridgei*, *vinacaus*. Subspecies: none. Chromosome number: not known.

Description Medium-sized mouse with slightly broadened skull and long slightly pro-odont incisors. Pelage soft and dense. Dorsal pelage grey or greyish-brown, slightly flecked with buff; hairs dark grey at base, buff at tip. Ventral pelage pale grey to brownish-grey; hairs grey at base, white at tip. Colour of dorsal and ventral pelage merge on flanks. Head somewhat broadened; cheeks pale grey to white. Chin and throat pale grey to white. Vibrissae dark. Ears oval, darkly pigmented, sparsely haired with scattered short white or buff hairs. Fore- and hindlimbs short, whitish above and below. Feet off-white, sometimes brown above. Tail moderately short (70% of HB), mostly naked and ringed with small scales; hairs sparse and short, white to grey-brown (sometimes hair white below, brown with white tips above). Emanates a very strong smell. Skull: broad (due to flaring zygomatic arches); postorbital ridge absent; upper incisor teeth ungrooved, long and pro-odont. Nipples $3 + 2 = 10$.

Geographic Variation Overall considerable variation in pelage colour (Hollister 1919, Misonne 1965a, Ansell 1978).

Zelotomys hildegardae

Similar Species

Z. woosnami. Incisors orthodont; southern Africa only.

Mastomys spp. (primarily *M. erythroleucus* and *M. natalensis*). On average slightly larger, upper incisor teeth orthodont; tail grey and relatively longer (ca. 90% of HB); up to 24 nipples arranged in two longitudinal rows.

Distribution Endemic to Africa. Eastern and Southern Rainforest–Savanna Mosaics, and Zambezian Woodland BZ in central and East Africa. Recorded from Angola, N Zambia, N Malawi, Tanzania, Kenya, W Uganda, Rwanda, Burundi, NE DR Congo and S Sudan. Musser & Carleton (2005) also list Central African Republic.

Habitat Moist grassy savanna and scrub, edge of swamps and forests (Misonne 1965a), and grasslands. Favours *Imperata* grasses in Serengeti N. P., Tanzania (Misonne & Verschuren 1966) and Queen Elizabeth N. P., Uganda (Delany 1964b, 1975). Syntopic in Virunga N. P. in E DR Congo with *Otomys irroratus*, *Aethomys kaiseri* and *Arvicanthis abyssinicus* (Verschuren *et al.* 1983). On the Nyika Plateau, Malawi, recorded from pine plantations and near houses (Hanney 1965).

Abundance Fairly low; usually comprises <3% of captured rodents. Comprised 2.15% of rodents caught in Queen Elizabeth N. P., Uganda, occurring in only two of four habitats sampled (Delany 1964b); 0.31% in Virunga N. P., DR Congo (Verschuren *et al.* 1983); and 2.6% (n = 349) in grassland of Rwenzori Mountains N. P., Uganda (Cheeseman 1975). In the crater area of Rwenzori Mountains N. P., estimated population density throughout year varied from 0.44 to 1.33 individuals/ha (Cheeseman 1975), dropping immediately after burning of savanna grasses. In Rwanda (Misonne 1965a), comprised 1.5% of rodents trapped, but 3.37% of rodents (n = 267) in owl pellets; perhaps more common in some areas than trapping results indicate.

Adaptations Terrestrial and nocturnal. In captivity, constant activity occurs throughout the night (n = 3 animals; Cheeseman 1975). Like shrews, these mice have a strong unpleasant smell, which may protect them from predators (Kingdon 1974). Makes a high-pitched whistling call (Delany 1975).

Foraging and Food Mainly insectivorous. Probably forages underneath grass cover (Kingdon 1974). Contents of stomachs have included Orthoptera (Delany 1964b), ‘insects’ (Misonne 1965a) and ‘remains of insects and fruits’ (Misonne & Verschuren 1966); myriapods and dung beetles are also eaten (Kingdon 1974). In captivity, eats meat (Delany 1975).

Social and Reproductive Behaviour No information.

Reproduction and Population Structure Pregnant ♀♀ recorded in Jun and Nov in Kenya (Hollister 1919, Southern & Hook 1963), and Feb, Mar, May–Jul in Uganda (Delany 1975); no information for other months. Litter-size: 3–7.

Predators, Parasites and Diseases Remains found in pellets of raptors in Rwanda (Misonne 1965a). Harbours various ectoparasites, e.g. Anoplura and Acarina (Benoit 1959, Colbo 1973, Fain 1976, Fain & Lukoschus 1977).

Conservation IUCN Category: Least Concern.

Zelotomys woosnami WOOSNAM'S BROAD-HEADED MOUSE (WOOSNAM'S ZELOTOMYS)

Fr. Souris de Woosnam; Ger. Woosnams Breitkopfmaus

Zelotomys woosnami (Schwann, 1906). Proc. Zool. Soc. Lond. 1906: 108. Kuruman, South Africa.

Taxonomy Originally described in the genus *Mus* and subsequently placed in the genus *Ochromys* (e.g. Shortridge 1934), and allied with *Aethomys*, *Rattus* and *Thallomys* (Musser & Carleton 2005). Synonyms: none. Chromosome number: not known.

Description Medium-sized, somewhat slender mouse with white tail. Pelage soft and smooth; hairs 15 mm on back. Dorsal pelage uniform pale grey to buff-grey; hairs slate-grey on basal two-thirds, pale grey on terminal third, some with black tip. Ventral pelage white; hairs pale grey at base, white at tip. Vibrissae soft, fine, dark, about 35 mm long. Ears medium-sized, oval, sparsely haired with a

narrow white ring around the base in adults. Chin and throat white. Fore- and hindlimbs short and slender, white above and below. Forefeet with four functional digits; Digit 1 vestigial. Hindfeet with five digits; Digits 1 and 5 shorter than other digits. Tail long (ca. 85% of HB), thin, entirely white, with short white hairs above and below, sometimes with dark tip. Juveniles darker in colour than adults. Head not broadened as in *Z. hildegardae*. Upper incisor teeth opisthodont, slender, ungrooved; molar cusps prominent. Nipples 3 + 2 = 10 (Shortridge 1934).

Geographic Variation None recorded.

*Zelotomys woosnami*

Similar Species

Z. hildegardae. Upper incisor teeth pro-odont; eastern Africa only; allopatric.

Mastomys spp. (primarily *M. coucha* and *M. natalensis*). On average slightly larger, upper incisor teeth orthodont; tail grey and relatively longer (ca. 90% of HB); up to 24 nipples arranged in two longitudinal rows.

Distribution Endemic to Africa. South-West Arid BZ (Kalahari Desert). Sparsely distributed where mean annual rainfall is 200–500 mm. Recorded from N and E Namibia, N, SW and C Botswana, NW South Africa, and extreme SW Angola.

Habitat Sparsely vegetated *Acacia* woodlands, savannas, riparian *Acacia*, open shrublands of *Acacia*, *Grewia* and *Terminalia*, and *Rhigozum* woodlands (SW Kalahari only). Prefers sandy to fine, consolidated soil (J. A. J. Nel unpubl.). In SW Kalahari, recorded in high dunes, *Acacia* savanna, and low dunes flanking dry river beds (Nel & Rautenbach 1975).

Abundance Generally occurs in low numbers over most of its range (but see below) (Nel & Rautenbach 1975). In the SW Kalahari, over 24 years of sampling, comprised 0.74% of small rodents ($n = 1905$) in the habitats where they were recorded. However, within a particular habitat, numbers may fluctuate widely; e.g. on the low dunes flanking the dry Nossob R., they comprised 0.62% (7 out of 1125) of rodents caught during 26 trapping sessions spanning 24 years. They were totally absent during 22 of these trapping sessions and comprised 0.87%, 1.64%, 1.90% and 4.55% of the rodents in four sessions. In a high dune habitat, ca. 4 km distant from the Nossob R., they comprised 0.97% of all rodents ($n = 304$) caught during 11 trapping sessions spanning 13 years; they were absent during nine trapping sessions, and comprised 4.65% and 2.22% of rodents in two sessions.

Adaptations Primarily terrestrial, but also adept climbers and able to jump from branch to branch, using the tail for balance (Birkenstock & Nel 1977). In captivity, observed to climb to 1 m. Nocturnal with three peaks of activity; active in short, regular cycles in captivity (Birkenstock & Nel 1977). They dig their own burrows under shrubs and trees; two excavated burrows were 40–55 cm deep with nest chambers filled with finely-shredded grass (Birkenstock & Nel 1977). At times, may inhabit burrows of other rodents, e.g. *Tatera* (now *Gerbilliscus*) (Shortridge 1934) or *Desmodillus* (Roberts 1951).

Foraging and Food Granivorous (Smithers 1971), omnivorous and carnivorous (Birkenstock & Nel 1977). Forage on ground. One stomach contained seeds (79%) and insects (21%); a second contained 100% flesh (Birkenstock & Nel 1977) and a third contained 75% seeds and 25% insects as well as nematode worms (De Graaff 1981). There is some evidence that the carcasses of other rats are eaten, and that scavenging may occur.

Social and Reproductive Behaviour Solitary and mutually intolerant. Individuals will attack, kill and partly consume conspecifics in captivity. In SW Kalahari, a ♂ and ♀ have been caught at the same trap station (twice) during the same trapping session while singletons were spaced 10–100 m apart ($n = 6$). Adults normally nest alone (Birkenstock & Nel 1977). Allogrooming between sexes is a prelude to mating.

Reproduction and Population Structure Birth of young occurs during wet months (Dec–Mar) (Smithers 1971, J. A. J. Nel unpubl.) as well as during the dry winter months (May–Aug) (J. A. J. Nel unpubl.). Litter-size: 4.7 (4–5; Birkenstock & Nel 1977). Embryo number: 2–11 (Shortridge 1934, Smithers 1971). Females have a postpartum oestrus. Minimum time between litters: 31 days. Sex ratio at birth in captivity 1 : 1.33. At birth, young altricial and hairless; hairs erupt by Day 6. First leave nest Day 12. Ears open Day 14. Eyes open Day 16–17. Weaned ca. Day 30. Young attain 80% of adult weight by Day 40 (Birkenstock & Nel 1977). Young do not nipple-cling.

Predators, Parasites and Diseases Predators unknown. Ectoparasites include two species of flea (one a vector of bubonic plague) and one species of tick (De Graaff 1981). Maggots of a parasitic fly (probably *Cordylobia* sp.) have been found in the scrotum, producing pus and disease (and in one animal had destroyed the testis) (Dollman 1910). Harbours nematodes *Physaloptera aduensis* adults and larvae, and *Spirura* sp. ♀♀ (A. Verster in litt.).

Conservation IUCN Category: Least Concern.

Subfamily OTOMYINAE – Vlei Rats and Whistling Rats

Otomyinae Thomas, 1897. Proc. Zool. Soc. Lond. 1896: 1017 (publ. 1897).

| | | |
|------------------------------|----------------|--------|
| <i>Otomys</i> (15 species) | Vlei Rats | p. 574 |
| <i>Parotomys</i> (2 species) | Whistling Rats | p. 596 |

The Otomyinae contains two genera and 17 species (Table 42) and represents a localized murid radiation that took place in sub-Saharan Africa. Species richness is highest in southern Africa and the East African mountains, with outlying species found in the highlands of Ethiopia, E Nigeria and Cameroon, and Angola. Species with morphologically primitive traits (*Parotomys* spp. and certain *Otomys* [*O. sloggetti* and *O. unisulcatus*]) are confined to drier regions of southern Africa; derived morphologies characterize more broadly distributed species groups, particularly those inhabiting the mountains and savannas of East Africa. The subfamily collectively occupies a wide range of environments and moisture conditions, but individual species tend to be stenotopic, occurring in savannas, sandy and semi-desert veldts, rocky or dense shrub associated with montane forest, sub-alpine and alpine grasslands, and wetlands (marshes, swamps, river edges and moorlands). Species are uniformly terrestrial, mostly diurnal and predominantly herbivorous; the diet of some species supplemented by seeds and berries.

Otomyinae rodents are stocky in build and medium to large in size. The pelage is long, soft and somewhat shaggy in mesic forms, or shorter and stiffer in xeric-adapted species. Dorsal pelage is normally brown, ranging from pale sandy or tawny-buff to dusky, with rufescent highlights in some forms; ventral pelage is usually greyish-white to dark grey, only weakly delineated from dorsal pelage. Pinnae are small and rounded, sparsely to densely furred. The hindfeet are relatively short and wide, with Digits 1 and 5 short and the plantar surface bearing six pads; otomyines characteristically possess a tuft of long ungual hairs that overarch the claws of the hindfeet. The tail is notably short, only half to three-quarters the length of head and body, and moderately well haired. There are four nipples in all species, arranged as two inguinal pairs.

The cranium is heavily built, moderately to strongly arched, with a narrow interorbital constriction and pronounced supraorbital ridges; rostrum is relatively short, with the nasal bones broadened near their tips, abruptly so in certain *Otomys*; zygomatic arches are nearly parallel-sided, deep over their mid-section and the zygomatic plate broad; anterior palatal foramina narrow, nearly as long as diastema; hard palate narrow and deeply corrugated; pterygoid fossa compressed and deeply recessed; anteroventral maxillary foramen very large, stapedial foramen present (except *O. angoniensis*), sphenofrontal foramen and squamosal-alisphenoid groove absent, alisphenoid strut present; ectotympanic part of auditory bullae are large (*Otomys*) or very large (*Parotomys*) relative to most Muridae, except certain Gerbillinae; malleus transitional between perpendicular and parallel form, the orbicular apophysis absent or minute; mandibular ramus very deep,

coronoid process short (Cockerell *et al.* 1914, Thomas 1918, Bohmann 1952, Carleton & Musser 1984, Pocock 1987). Dental features collectively define the subfamily as unique among murids: upper incisors are broad, opisthodont, each with at least one conspicuous groove (except *Parotomys littledalei*) and a second faint groove in some species; lower incisors also with one (most species) or two (*O. typus*) grooves, or none (*Parotomys* and some *Otomys*). Molar rows long, close set and moderately hypsodont; occlusal surfaces planar, formed of compressed transverse laminae with individual cusps suppressed; M¹ (three laminae) and M² (two laminae) much shorter than M³; M³ and M₁ longest in their respective toothrows; M³ with two or three laminae (*P. brantsii*, *P. littledalei*), four, five or six laminae (*O. denti*, *O. saundersiae*, *O. sloggetti*, *O. unisulcatus*), commonly seven or eight (*O. burtoni*, *O. cuanzensis*, *O. irroratus*, *O. lacustris*, *O. anchietae*, *O. angoniensis*, *O. typus*, *O. tropicalis*, *O. barbouri*, *O. occidentalis*), and exceptionally nine or ten (*O. laminatus*, some *O. typus*); lower first molar with two laminae (*O. unisulcatus*), three or four laminae in most species, five to seven in certain *Otomys* (*O. anchietae*, *O. barbouri*, *O. lacustris*, *O. laminatus*, *O. occidentalis*) (Dollman 1915, Thomas 1918, Roberts 1951, Bohmann 1952). The transverse laminae on the molar teeth are very characteristic of the genus, and are associated with mastication of abrasive silica-rich grasses (Figure 91).

Adaptations to an herbivorous trophic niche and grassland ecology impart a characteristic otomyine form, one reminiscent of other muroid lineages that have radiated into similar niches around the world. Many authors (e.g. Kingdon 1974) have emphasized external similarities between otomyine species (Muridae) and those of Arvicolinae (Cricetidae), notably as expressed by their stocky body form and short limbs, blunt rostrum and small pinnae, and a tail shorter than head and body. The resemblance extends even to details of molar size, form and variability of the molar teeth, especially the posterior portion of M³ and anterior portion of M₁ (e.g. Guthrie 1971); such dental differences have figured prominently in the taxonomic diagnoses of genera and species within both groups. No otomyine, however, has attained ever-growing molars (hypsodonty) nor the derived arrangements of enamel microstructure as found in arvicolines (von Koenigswald 1980). Phylogenetic augmentation of molar triangles (Arvicolinae) or laminae (Otomyinae) and increased crown height, accompanied by remodelling of the cranium and attached zygomasseteric musculature, have served to enhance propalinal grinding in both groups and in part explain their dietary specialization and evolutionary success in grassland environments. Further, otomyines, like arvicolines (Vorontsov 1967), possess a long and anatomically elaborate caecum and colon (Perrin & Curtis 1980, Jackson & Spinks 1998), which are the principal sites for microbial fermentation of cellulose-rich foods. Morphological convergence and eco-behavioural equivalence are equally striking between otomyines and certain other muroids. For example, *Otomys*

and New World Cotton Rats (*Sigmodon*, Sigmodontinae) are similar in external appearance and form, degree of molar hypsodonty and precocial development of young; likewise, *Parotomys* and African Sand Rats (Gerbillinae: *Psammomys*) are convergent in pelage colour and form, colonial social structure and alarm calls, existence in xeric habitats, and dietary reliance upon salt-rich plants.

Following Thomas (1897), otomyines have been ranked as a subfamily of Muridae, whether the family is defined *sensu lato* (Ellerman 1941, Roberts 1951) or *sensu stricto* (Miller & Gidley 1918, Simpson 1945). Although some have classified Otomyinae with Cricetidae (Kingdon 1974, Misonne 1974) or Nesomyidae (Chaline *et al.* 1977, Lavocat 1978), anatomical and palaeontological evidence unequivocally affirms their phyletic origin from early African murids, possibly arvicanthine-like forms (Pocock 1976, Carleton & Musser 1984, Breed 1995, S  n  gas 2001). Similarly, a diverse suite of molecular data uniformly portrays the evolutionary heritage of *Otomys* as murid, not cricetid (Contrafatto *et al.* 1994, Watts & Baverstock 1995a, Michaux & Catzeflis 2000, Michaux *et*

al. 2001, Jansa & Weksler 2004), in particular as a sister-group to *Arvicanthis* and its kin, which constitute a large clade within African Murinae (Chevret *et al.* 1993a, Ducroz *et al.* 2001). Molecular clock estimates place the split from arvicanthine murids about 7–9.5 mya (Chevret *et al.* 1993a, Ducroz *et al.* 2001), a time-frame in broad agreement with fossil data insofar as known (S  n  gas 2001) and with the late Miocene proliferation of C₄ grass-dominated savannas in Africa (Jacobs *et al.* 1999).

The geological occurrence of Otomyinae ranges from the late Miocene to Recent in southern Africa (S  n  gas & Avery 1998) and from the early Pleistocene to Recent in East Africa (Denys 1989b). Extinct species certainly assignable to *Otomys* proper appear in the middle Pliocene of South Africa (Pocock 1987) and early Pleistocene of Tanzania (Denys 1989b). One other fossil murid, the Miocene *Microtia* from the Gargano Islands off Italy (Freudenthal 1976), exhibits comparably enlarged M³ and M₁, but it retains a chevron arrangement of cusps, not the planar laminate occlusion and cusp suppression characteristic of Otomyinae.

Table 42. Species in the subfamily Otomyinae. Arranged in order of increasing number of laminae on M³. Note that although 17 species are listed below, recent reviews in 2011 suggest that several of these are composite species and therefore the total number of species is 31 (see also text).

| Species | Laminae on M ³ ^a | Laminae on M ₁ ^a | Grooves on each upper incisor | Grooves on each lower incisor | Petrotympenic foramen | Nasal bones ^b | |
|--|--|--|-------------------------------|---|-----------------------|--------------------------|--|
| <i>Parotomys brantsii</i> | 2 | 4 | 2 (deep outer, shallow inner) | 0 | Round | Barely expanded | |

| <i>Otomys angoniensis</i> | 7 (6) | 4 | 1 | 2 (deep medially, shallow laterally); sometimes 1 | Slit-like | Moderately expanded | |
| <i>Otomys typus</i> s.l. ^g | 6, 7, 8, 9 | 4 | 1 | 2 (deep) | Round | Sharply expanded | |
| <i>Otomys tropicalis</i> ^h | 7 (8) | 4 | 1 | 2 (deep medially, shallow laterally) | Round | Moderately expanded | |
| <i>Otomys barbouri</i> | 7 (8) | 5 | 1 | 1 | Round | Sharply expanded | |
| <i>Otomys occidentalis</i> | 8 (7) | 5 | 1 | 1 | Slit-like | Sharply expanded | |
| <i>Otomys laminatus</i> | 8–10 | 7 | 1 | 2 (deep medially, shallow laterally) | Round | Sharply expanded | |

^a Where two numerals are given, each is observed in roughly equal frequency; numerals in brackets indicate a less frequently observed number of laminae.

^b See Fig 92 for illustration of the shape of nasal bones.

^c Plus small circular posterior lamina on M³.

^d Plus partial incomplete anterior lamina on M₁.

^e Taylor *et al.* (2009a) recognize *sungae* from the Eastern Arc as a distinct species, previously regarded to be a synonym of *denti*.

^f Taylor *et al.* (2009a) provide evidence that *saundersiae* should be retained as a synonym of *irroratus* and the name *karoensis* should instead be used to describe the small, pallid species from the Cape.

For so small and morphologically distinctive a group, the taxonomy of otomyine rodents remains unsettled at the family, genus, and species levels. Disclosure of close relationship to arvicanthine rodents has led investigators to propose that otomyines should be ranked as a tribe within Murinae (Ducroz *et al.* 2001, S  n  gas 2001). Although close phyletic association of otomyine rodents with other African murids is incontestable, decision on their taxonomic rank will be better informed by expanded sampling of genera from Asia and Indo-Australia. Generic arrangements within the subfamily have ranged from only a single genus *Otomys* (Bohmann 1952), to the customary two, *Otomys* and *Parotomys* (Ellerman 1941, Misonne 1974), to as many as three (*Otomys*, *Parotomys* and *Myotomys* – Thomas 1918, Musser & Carleton 2005) or five genera (*Otomys*, *Parotomys*, *Myotomys*, *Anchotomys* and *Lamotomys* – Roberts 1951). Improved comprehension of phyletic relationships among species should provide a sounder basis for delimiting genera. Recent studies, for example, have revealed that *Otomys*, as its specific contents are usually denoted, is polyphyletic; in particular, the species *O. sloggetti* and/or *O. unisulcatus* (both placed in

the genus *Myotomys* by Musser & Carleton [2005]) demonstrate close kinship with species of *Parotomys* (Taylor *et al.* 1989, Bernard *et al.* 1991, Meester *et al.* 1992, Contrafatto *et al.* 1994, Musser & Carleton 2005). Specific diversity within *Otomys* has been historically masked by uncritical application of the biological species concept and an exceptionally forgiving interpretation of subspecies. This practice, applied over the middle 1900s, culminated in morphologically indefinable species, such as *O. irroratus*, *O. tropicalis* and *O. typus*, whose altitudinal and geographic distributions were improbably broad (e.g. Bohmann 1952, Ellerman *et al.* 1953, Dieterlen 1968, Misonne 1974, Petter 1982). The removal of diagnosable, genetically homogeneous species from these polyphyletic constructs is progressing but still requires much basic revision (see Taylor & Kumirai 2001 and Musser & Carleton 2005 for different estimates of species diversity). In view of this on-going research, only the two traditional genera – *Otomys* with 15 species and *Parotomys* with two species – are recognized here.

Michael D. Carleton

^gThis species represents a highly variable complex comprising 12 composite species. The values presented here cover the range of the complex and were obtained from Taylor *et al.* (2011).

^hCarleton & Byrne (2006) regard *dollmani* as a distinct species, previously recognized as a synonym of *tropicalis*.

ⁱTaylor *et al.* (2009b) and Engelbrecht *et al.* (2011) recognize two species within *irroratus s.l.*, these being *irroratus s.s.* and *auratus*.

GENUS *Otomys*

Vlei Rats

Otomys F. Cuvier, 1824. Dents des Mammifères, p. 255. Type species: *Euryotis irrorata* Brants, 1827.

The genus *Otomys* contains at least 15 species (Table 42, but see also below) and has a widespread distribution in semi-arid, montane and mesic grassland savanna habitats in southern Africa, and, more discontinuously, in montane, alpine and mesic grassland savanna habitats in East Africa, Angola, E DR Congo, Rwanda, Burundi, Ethiopia, S Sudan and the highlands of Cameroon and E Nigeria. Most species in the genus have rather restricted distributional and altitudinal ranges, and most (except *O. unisulcatus*) are associated with

damp grasslands and swamps from close to sea level to ca. 4300 m on mountains. The diet is exclusively grass, which is masticated by the highly specialized molar teeth.

The genus is characterized by medium to large body size, stocky build, shaggy, dark greyish-brown dull pelage, short tail, short limbs and four digits on each fore- and hindfoot. In their conservative, vole-like appearance they are thus very similar to the whistling rats (*Parotomys*), although the latter tend to be much paler in colouration, with proportionately larger head and expanded auditory bullae (Taylor *et al.* 2004b), the last-mentioned feature being an adaptation common to many species of rodents living in arid habitats. The skull is solidly built, zygoma are thick and almost parallel, zygomatic plate is large with forwardly curving anterior edge, anterior palatine foramina are short ending well anterior to M^1 , and the upper incisors are wide and opisthodont, each with one or two grooves (Figure 91). The upper and lower cheekteeth ($M1-M3$) are very distinctive with a highly derived lamellar molar pattern, and M^3 and M_1 are especially elongated, more so than in members of *Parotomys*. The nasal bone varies in shape in different species – it is either small and barely expanded or large and greatly expanded (Figure 92). The petrotympanic (or stapedial) foramen may be round or slit-like (Figure 93). Further details of the external and skull morphology of this genus are shared with species of *Parotomys* (see also subfamily profile).

The common names for the genus (Vlei Rats, Groove-toothed Rats, Laminate-toothed Rats) refer to their preferred habitat (vlei = swamp) and to the structure of the incisors (grooved) and cheekteeth (laminate).

The number of species in the genus is controversial. Musser & Carleton (1993) recognized 12 species, and later (2005) recognized 19 species (excluding two species they classified in *Myotomys*, which we here retain in *Otomys*: *O. unisulcatus* and *O. sloggetti*). Whilst acknowledging that it is an underestimate (and pending more accurate definition of species limits), we here recognize 15 species (following Dieterlen & Van der Straeten 1992, Musser & Carleton 1993, Taylor & Kumirai 2001, Taylor *et al.* 2005): *O. anchietae*, *O. angoniensis*, *O. barbouri*, *O. burtoni*, *O. cuanzensis*, *O. denti*, *O. irroratus*, *O. lacustris*, *O. laminatus*, *O. occidentalis*, *O. saundersiae*, *O. sloggetti*, *O. tropicalis*, *O. typus* and *O. unisulcatus*. Musser & Carleton (2005) recognize a further six species: *maximus* (considered here to be a subspecies of *angoniensis*; see Bronner & Meester 1988, and sequence

Otomys typus.

ABOVE: Figure 91. Skull and mandible of *Otomys angoniensis* (HC 2776).

RIGHT: Figure 92. Evolutionary trend in the shape of the nasal bone (viewed dorsally with anterior end at top) in species of the subfamily Otomyinae. Left: barely expanded anteriorly, the primitive state, e.g. *Parotomys* spp. Centre: moderately expanded anteriorly, e.g. *Otomys angoniensis*. Right: sharply expanded anteriorly, the most advanced state, e.g. *Otomys irroratus* (after original by P. Taylor).

Figure 93. Basicranial region of skull of *Otomys* showing the two shapes of the petrotympanic foramen. *O. angoniensis* (left) with slit-like petrotympanic foramen; *O. irroratus* (right) with round petrotympanic foramen (after Meester *et al.* 1986). Foramen magnum black; mastoid process points to right below the auditory bulla.

data of Maree 2002), *orestes* (previously a synonym of *O. tropicalis* or *O. typus*), *dollmani* (previously a synonym of *O. tropicalis*), *jacksoni*, *dartmouthi* and *uzungwensis*. The last three listed species were previously considered as southern alpine-adapted forms of *O. typus* but recent molecular and morphological data (Taylor *et al.* 2011) support their validity (and that of *zinki* from Mt Kilimanjaro and *thomasi* from the Mau Escarpment of Kenya) as distinct taxa unrelated to *typus* s.s. from Ethiopia. Taylor *et al.* (2011) also provide evidence of further speciation within *O. typus* s.s. from Ethiopia, with six Ethiopian species proposed, including *typus*, *fortior*, *helleri* and three newly described species, *cheesmani*, *simiensis* and *yaldeni*. Further justification of the status of *dollmani* and *orestes* as valid species is provided by Carleton & Byrne (2006) and Taylor *et al.* (2011). Taylor *et al.* (2009a) elevated *sungae* (previously a synonym of *O. denti*) to species status. Musser & Carleton (2005) follow Taylor *et al.* (2005) in considering *saundersiae* to be a valid taxon; however Taylor *et al.* (2009b) endorse Taylor *et al.* (1993b), providing convincing molecular and karyotypic evidence to show that *saundersiae* is a synonym of *irroratus*, and *karoensis* is the valid name for the smaller-sized species from the Western Cape. The small-sized species from northern Eastern Cape and southern Free State Provinces of South Africa are provisionally assigned to *karoensis* although ongoing molecular study seems to show they may be distinct. Within *O. irroratus*, Taylor *et al.* (2009b) and Engelbrecht *et al.* (2011) demonstrate two divergent molecular clades: one from the Fynbos Biome (*O. irroratus* s.s.) and the second from the Highveld of South Africa extending into the Zimbabwe Highlands (for which the name *O. auratus* is available). These studies suggest that there are now 31 species of *Otomys*; it has not been possible to include separate profiles for the new species described in 2009 and 2011.

The genus *Otomys* (Vlei Rats) is closely related to the genus *Parotomys* (Whistling Rats); together the two genera comprise the

Afrotropical murid subfamily Otomyinae. The monophyly of *Otomys* has been questioned on biochemical, molecular and morphological grounds. Two species, *O. unisulcatus* and *O. sloggetti* (*Myotomys* of Thomas [1918]), group phylogenetically closer to *Parotomys* than to other species of *Otomys* (Pocock 1976, Taylor *et al.* 1989, Contratto *et al.* 1994, Maree 2002, Taylor *et al.* 2004a, b). Although Musser & Carleton (2005) recognize the genus *Myotomys*, the monophyly of *Myotomys* is not supported by recent molecular and morphological cladistic analyses, and the most cladistically correct solution may be to include *Parotomys* species in the genus *Otomys* (Maree 2002, Taylor *et al.* 2004a).

Some authors recognize Vlei Rats as a distinct subfamily within the Muridae, or as a family, while others have placed them within Cricetidae and even Nesomyidae. Here, *Otomys* is included with *Parotomys* in the subfamily Otomyinae of the family Muridae. An alternative arrangement, based on recent palaeontological and molecular data, supports the allocation of *Otomys* and *Parotomys* in a tribe (the Otomyini) within the family Muridae (Ducroz *et al.* 2001, S  n  gas 2001). The South African fossil species, *Euryotomys pelomyoides* (6.0–4.5 mya) and *E. boliti* (4–5 mya) provide strong links between true murids and modern *Otomys* (Pocock 1976, Denys 1989b, Chevret *et al.* 1993a, Avery 1998, S  n  gas & S  n  gas 2001). The earliest true *Otomys* appeared first in South Africa (*O. cf. gracilis*, 3.0–3.5 mya), and later in East Africa (*O. petteri*, at 1.5–2.0 mya), suggesting a southern African origin of this genus. On the basis of DNA–DNA hybridization (Chevret *et al.* 1993a), the ancestor of Otomyini split from the Arvicanthine division of murids at around 7 mya. According to the protein molecular clock, *Otomys* and *Parotomys* may have split at around 6.5–5.5 mya (Taylor *et al.* 1989).

A relatively low number of five to six laminae in M^3 was present in ancestral *Otomys* species, as evidenced by the extinct *O. gracilis* in South Africa, with a subsequent trend towards an increasing number of laminae as shown in extant species (Denys 1989b, Chevret *et al.* 1993a). Bohmann (1952) postulated that successive radiations within the genus occurred from South Africa northwards into East Africa, Angola and West Africa, coinciding with mesic pluvial periods during the Pleistocene. At this time, montane forest–grassland mosaics extended to lower altitudes and became geographically continuous between southern Africa and East Africa. However, on fossil evidence, Denys (2003) postulated a single northwards dispersal followed by further speciation in East Africa, a scenario supported by recent molecular and morphometric data (P. J. Taylor, in litt.).

The taxonomy of the group is highly unstable due to variability in diagnostic characters. Species are distinguished by the number of laminae in M^3 and M_1 , the number and form of grooves on the incisors, shape of the nasal bone and shape of the petrotympanic foramen (see Table 42).

P. J. Taylor

***Otomys anchietae* ANCHIETA'S VLEI RAT (ANGOLAN VLEI RAT)**

Fr. Rat du vlei d'Anchiete; Ger. Anchietas Lamellenzahnratte

Otomys anchietae (Bocage, 1882). J. Sci. Acad. Lisbon 9: 26. Caconda, Huila, Angola.

Taxonomy Originally described in the genus *Euryotis*. Based on having five laminae in M_1 , some authors include *lacustris*, *occidentalis* and *barbouri* in this species. However, Dieterlen & Van der Straeten (1992) treated it as a species separate from *lacustris*, *occidentalis* and *barbouri*, a decision supported on morphometric and morphological grounds (Taylor & Kumirai 2001, Taylor *et al.* 2004a). Synonyms: none. Chromosome number: not known.

Description Very large, stoutly built rat with large, blunt head and short tail. Mean HB larger than any other *Otomys* (HB: >209 mm, skull length: >45 mm). Pelage soft, fine and thick. Dorsal pelage blackish tinged with 'pinkish buff'. Ventral pelage near cinnamon. Tail short (ca. 56% of HB), black above, paler below, sparsely haired. Each upper incisor with one deep and one shallow groove, each lower incisor with one deep groove, very occasionally a second faint groove. M^3 with six, seven (typically) or eight laminae. M_1 with five or (occasionally) six laminae. Petrotympanic foramen round. Nasal bones moderately expanded. Nipples $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species

O. angoniensis: M_1 with four laminae; petrotympanic foramen slit-like; partially sympatric in Angola (*O. o. maximus* only).

O. cuanzensis: M_1 with four laminae; HB, HF and M^1 – M^3 probably longer, marginally sympatric.

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded only in NE Angola, where associated with the rivers of the Congo Basin drainage, and in C and SW Angola, where it is narrowly sympatric with *Otomys cuanzensis* and *Otomys angoniensis maximus* (Crawford-Cabral 1998).

Habitat Riverine habitats in the Congo Basin in NE Angola, and mesic grasslands and moist savannas at higher altitudes of the central plateaux (>1500 m) of Angola.

Abundance No information.

Remarks Very little is known about this species. Apparently makes a screeching sound 'like a squirrel'. Lactating ♀♀ collected in Aug (Hill & Carter 1941).

Conservation IUCN Category: Least Concern.

P. J. Taylor

Otomys angoniensis ANGONI VLEI RAT

Fr. Rat du vlei d'Angoni; Ger. Angonis-Lamellenzahnratte

Otomys angoniensis Wroughton, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 274. M'Kombhuie, Malawi (= Matipa Forest, Misuku Range, Malawi; *fide* Ansell & Dowsett 1991). 7000 ft (2120 m).

Taxonomy *Otomys angoniensis maximus* may be a distinct species (Musser & Carleton 1993, 2005, Crawford-Cabral 1998), but morphometric overlap (Bronner & Meester 1988, P. J. Taylor unpubl.) and genetic similarity (Maree 2002) suggest *maximus* should be retained as a subspecies of *O. angoniensis*. The Angolan *cuanzensis*, previously allocated to *angoniensis*, is recognized as a distinct species following Musser & Carleton (2005). Synonyms: *canescens*, *divinorum*, *elassodon*, *mashona*, *maximus*, *nyikae*, *pretoriae*, *rowleyi*, *sabiensis*, *tugelensis*. Subspecies: three. Chromosome number: $2n = 56$, $aFN = 54$. All chromosomes are acrocentric. X-chromosome is second largest member of the karyotype and Y-chromosome is smallest. Limited G-band homology detected between this species and *O. irroratus* (Contrafatto *et al.* 1992c).

Description Large stocky rat with dense shaggy pelage. Dorsal pelage pale to dark greyish-buffy. Colour varies geographically from darker to paler, with the palest individuals on Mt Kilimanjaro. Ventral pelage dark grey. Head large. Small, well-haired ears held close to head. Tail short (ca. 55% of HB). Each upper incisor with single groove. Each lower incisor with one deep and one shallow groove (except for *O. a. maximus* where the shallow groove is practically invisible). M^3 with seven laminae (occasionally six). M_1 with four laminae. Nasal bones moderately expanded. Petrotympanic foramen small, slit-like (as in *O. burtoni* and *O. sloggetti*). Baculum spatulate basally with central raised portion in ventral view; length of proximal portion ca. 4 mm, maximum width ca. 1 mm (Davis 1973). Body size varies geographically (see Measurements). Nipples: $0 + 2 = 4$.

Geographic Variation Three subspecies may be recognized (P. J. Taylor unpubl.):

- O. a. angoniensis*: Kenya, Tanzania, Malawi, Mozambique, Zimbabwe. Similar size to *O. a. tugelensis*, smaller than *O. t. maximus*; HB: 141–189 mm, GLS: 35–40 mm, but wider interorbital distance (>4.5 mm; P. J. Taylor, unpubl.). Each lower incisor with deep outer and shallow inner groove.
- O. a. maximus*: N Botswana, NW Zambia, SW & SE Angola, SE & E DR Congo. Largest subspecies; HB: 154–207 mm, GLS: 40–49 mm (Roberts 1951, P. J. Taylor unpubl.). Each lower incisor with single groove.
- O. a. tugelensis*: South Africa, SE Botswana. Similar size to *O. a. angoniensis*, comparatively narrow interorbital distance (<4.5 mm). Each lower incisor with deep outer and shallow inner groove.

Similar Species

- O. irroratus*. Petrotympanic foramen round in shape; dorsal pelage less buffy-coloured; on average larger; six (occasionally seven) laminae in M^3 ; partly sympatric.
- O. laminatus*. More than eight laminae in M^3 .

O. tropicalis. Round petrotympanic foramen.

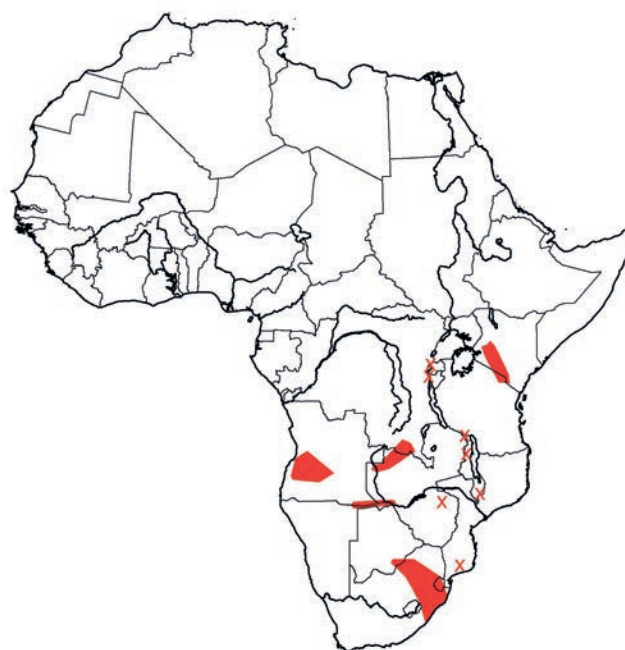

O. denti, *O. sloggetti* and *O. unisulcatus*. Single groove in each lower incisor.

O. typus. Two deep grooves in each lower incisor.

O. anchietae, *O. barbouri*, *O. lacustris*, *O. occidentalis*. Five laminae in M_1 .

Distribution Endemic to Africa. Zambezan Woodland BZ and southern part of the Somalia–Masai Bushland BZ; also present in highland habitats throughout the eastern side of the continent. Recorded from South Africa, Swaziland, Zimbabwe, Mozambique, Malawi, Angola, Zambia, DR Congo, Rwanda, Tanzania and Kenya (Ansell 1960, Misonne 1974, Ansell & Dowsett 1988, Bronner & Meester 1988, Crawford Cabral 1998). Records from outlying Eastern Cape Province, South Africa (De Graaff 1981, Bronner & Meester 1988) could not be corroborated on the basis of known museum specimens (Lynch 1994). Specimens having slit-like petrotympanic foramina from Uvira (SMNS) and Albert N. P. (MNHN) extend the known distribution into E DR Congo and Rwanda, respectively. Distribution in East Africa is patchy. See also Geographic Variation above.

Habitat Mesic grassland and savanna woodland habitats (from coastal to high montane habitats, mostly at <1000 m in South Africa), generally in close proximity to wetlands or water. Drier habitats may also be occupied during the wet season. Where in sympatry with *O. irroratus*, *O. angoniensis* occupies more xeric habitats (plant associations providing lower ground cover). On a study area near Pretoria (South Africa), positive association recorded between *O. a. tugelensis* and

Otomys angoniensis

several plant species including *Helictotrichon turgidulum*, *Cynodon dactylon*, *Melilotus alba*, *Hyparrhenia dregeana*, *Berkheya radula*, *Chironia palustris* and *Conyza podocephala*. On the same study area, *O. irroratus* was negatively associated with the above plants, preferring species that provide denser ground cover (Davis 1973). In Malawi, occurs only in montane grasslands (Hanney 1965).

Abundance Abundant in suitable habitats. A stable population in the highlands of Kenya had a density of 30/ha. Population size appears to be regulated by availability of cover (Taylor & Green 1976). Presence of this species is indicated by short chopped lengths of grass and green moist faecal pellets.

Adaptations Diurnal, crepuscular or nocturnal, depending possibly on the level of owl predation. Shaggy dark pelage, vole-like body form with short tail, and sturdy skull are adaptations for camouflage and burrowing through runways in dense swampy habitats. Large nasal bones are adaptation for enhanced olfactory ability. Laminate molars, long spiralled small intestine and large complex caecum are adaptations for strict herbivory. Coprophagy may aid caecal fermentation and vitamin metabolism (Perrin & Curtis 1980). Distinctive 'runways' are constructed in dense grass, and are used by other species of small mammals. Constructs dome-shaped grass nests.

Foraging and Food Stems and rhizomes of grass, fine reeds and other monocotyledonous plants. In Kenya, diet includes dicotyledonous plants (particularly in winter), bark of shrubs and trees (e.g. *Lantana*, *Eucalyptus*) and seeds from wheat (Taylor & Green 1976). In Malawi, diet is entirely green grass (Hanney 1965).

Social and Reproductive Behaviour Solitary, pairs or small family groups. In captivity, less vocal (very few audible sounds recorded) but less shy than *O. irroratus* (N. Pillay pers. comm.).

Reproduction and Population Structure Polyoestrous. In Kenya, breeding continues throughout the year with a peak of activity in the wet season (Taylor & Green 1976). In Malawi, pregnant ♀♀ recorded in the dry season (May, Jul and Nov) (Hanney 1965). In southern Africa, young recorded only in spring and summer (Sep–Jan); no breeding recorded during mid-winter (Jun, Jul). Embryo number: 1–5, usually 2 or 3 (Bronner & Meester 1988). In captivity, gestation: 37 days. Mean litter-size: 3.1 (2–5), n = 48 (Phillips *et al.* 1997). At birth, young precocial with erupted incisors and capable of nipple-clinging immediately after birth; mean weight at birth 11.4 g. Minimum age at sexual maturity: five weeks (♀♀) to eight weeks (♂♂). *Otomys angoniensis* is less K-selected than either *O. irroratus* or *O. sloggetti robertsi* and more K-selected than *O. unisulcatus* (Phillips *et al.* 1997).

Predators, Parasites and Diseases Predators include owls (African Grass-owl *Tyto capensis*, Marsh Owl *Asio capensis*, Barn Owl *Tyto alba*, Spotted Eagle-owl *Bubo africanus*), felids (e.g. Serval *Felis serval*), jackals (Black-backed Jackal *Canis mesomelas*, Side-striped Jackal *Canis adustus*), mongooses (e.g. Grey mongoose *Herpestes ichneumon* and

Water Mongoose *Atilax paludinosus*), genets (*Genetta tigrina*), Civet (*Civettictus civetta*), snakes (e.g. Puff Adder *Bitis arietans*) and humans (e.g. tribespeople in Botswana, where many are eaten following annual reed-burning ceremonies) (Shortridge 1934, Dean 1978b, Skinner & Smithers 1990). On Zomba Plateau, Malawi, was the most numerous prey item of African Grass-owls, comprising 47% of small mammals (n = 101) in disintegrating pellets, and 58% of the food biomass; and 24% of prey items and 40% of prey biomass in 21 intact pellets (Happold & Happold 1986).

Bronner & Meester (1988) list some 30 species of ecto- and endoparasites, including fleas (13 species), mites (2 species), lice (1 species), ticks (4 species), chiggers (2 species), filaria and nematodes (2 species), and at least three zoonoses in which Angoni Vlei Rats may be intermediate hosts of diseases of humans (rickettsia, plague and melioidosis). They are susceptible themselves to bilharzia.

Conservation IUCN Category: Least Concern.

R. J. Taylor

Otomys barbouri BARBOUR'S VLEI RAT

Fr. Rat du vlei de Barbour; Ger. Barbours Lamellenzahnratte

Otomys barbouri Lawrence and Loveridge, 1953. Bull. Mus. Comp. Zool., Harvard 110: 63. Mt Elgon, Uganda. 10,500 ft (3200 m).

Taxonomy Musser & Carleton (1993) consider *barbouri* to be a synonym of *O. anchietae*. In contrast, *barbouri* was recognized as a valid species by Dieterlen & Van der Straeten (1992) and Musser & Carleton (2005) on the basis of morphometrics and cranial variables. Taylor & Kumirai (2001) also recognize *barbouri* as a valid species on the basis of PCA and discriminant functions analysis for 16 cranial variables. Synonyms: none. Chromosome number: $2n = \text{'at least 66'}$ (P. J. Taylor, unpubl.).

Description Large vole-like rat with a long shaggy pelage. Hairs very long (20–35 mm). Dorsal pelage dull reddish-brown speckled with black, dorsal hairs reddish-brown, with black tips. Flanks slightly paler. Ventral pelage conspicuously paler than dorsal pelage. Fore- and hindfeet greyish-brown. Tail short (ca. 45% of HB), blackish-brown, with scales and short dark bristles. Each upper incisor and each lower incisor with single groove. M^3 with seven (occasionally eight) laminae. M_1 with five laminae. Nasal bones sharply expanded. Petrotympanic foramen round. Sexual dimorphism present: HB and T significantly larger in adult ♂♂, ears significantly larger in ♀♀, but no significant difference in hindfoot length (Clausnitzer 2003). Nipples: $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species

O. lacustris. Tail longer (ca. 65% of HB); M^3 with six (occasionally seven) laminae; Tanzania, Malawi and Kenya (?) only.

Otomys barbouri

O. typus. Smaller; two grooves in each lower incisor; M^3 with seven laminae; M_1 with four laminae; highlands of Ethiopia, Kenya, Uganda, Tanzania, Zambia, Malawi. Sympatric on Mt Elgon.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only above 3200 m on Mt Elgon (Uganda, Kenya).

Habitat Afroalpine grasslands and glades above 3200 m up to the peaks (4300 m). Preferred habitats are richly structured dense grasslands, bush–grassland mosaics on moist soils, and swamps with *Carex runsoroensi*. Pure tussock grasslands (mainly *Festuca pilgeri*) on drier soils are avoided, and inhabited by the syntopic *Otomys typus* (Clausnitzer 2000, 2001, 2003).

Abundance Abundant in and near swamps, and common in grasslands and bush–grassland mosaics (Clausnitzer 2001, 2003). Density varies from 15/ha (grassland, bush–grassland mosaic) to 25/ha (swamps). Comprised 45–50% of all rodents trapped in suitable habitats on Mt Elgon (V. Clausnitzer unpubl.). Density remains constant throughout the year.

Adaptations Diurnal and terrestrial. Lives in an extensive, surface and very shallow subterranean runway system, and seeks shelter in dense vegetation. Temperature in preferred habitat is often below freezing at night; however, these *Otomys* do not build nests or show eusocial behaviour (huddling) as a protection from the cold. The teeth and digestive system are modified for an entirely herbivorous diet: the molars are laminate, and the caecum and large intestine are relatively long (small intestine 40%, caecum 21%, large intestine 39%) (Clausnitzer 2003). See also genus profile.

Foraging and Food Herbivorous. Forages on leaves and flowers; prefers receptacles of *Helichrysum* flowers. Diet (on an annual basis) as assessed by analysis of faecal and stomach contents: 24% *Festuca pilgeri*, 21% other grasses, 30% parts of Compositae flowers (mainly *Helichrysum*), 6% other flowers, 18% dicotyledons (leaves) (n [faeces] = 89, n [stomach] = 32; Uganda; V. Clausnitzer unpubl.). Diet shows slight seasonal variation (Clausnitzer 2003).

Social and Reproductive Behaviour Solitary (except when ♀♀ are looking after young) and unsociable. Individuals utter chittering warning noises whenever they meet. Non-territorial; home-ranges overlap to a large extent. Home-range: 361 m^2 ($n = 49$, range: $0.21\text{--}2461 \text{ m}^2$). No significant difference in home-range area between the sexes and between seasons (Clausnitzer 2000, 2001, 2003).

Reproduction and Population Structure Reproduction is non-seasonal and occurs in all months of the year. In each month of the year, 20–60% of ♀♀ pregnant, and 20–100% lactating. Litter-

size: one ($n = 8$, Clausnitzer 2003). At birth, young are precocial and fully furred. Females have more than one litter/year. Populations are stable throughout the year without any seasonal fluctuations in numbers. Juveniles form about 10% of the population at all times (Clausnitzer 2003). Sex ratio 1 : 1 throughout year. Life expectancy: at least 15 months.

Predators, Parasites and Diseases Servals are a major predator: teeth of *Otomys* (*O. typus* and *O. barbouri*) comprised 95% of all teeth present in 100 faecal samples (Clausnitzer 2003). Birds of prey (including Augur Buzzard *Buteo rufofuscus*) may be minor predators. Fleas (species unknown) normally found on most adult individuals. No records of endoparasites (Clausnitzer 2003).

Conservation IUCN Category: Endangered.

Conservation of the very small geographical range (Mt Elgon above 3000 m) is essential.

Otomys burtoni BURTON'S VLEI RAT

Fr. Rat du vlei de Burton; Ger. Burtons Lamellenzahnratte

Otomys burtoni Thomas, 1918. Ann. Mag. Nat. Hist., ser. 9, 2: 210. Cameroon Mt, Cameroon. 7000 ft (2100 m).

Taxonomy Previously treated as a subspecies or synonym of *O. tropicalis*. The presence of a slit-like petrotympanic foramen, shared with *O. angoniensis* and *O. sloggetti* (cf. round-shaped in all other *Otomys*), together with six or seven laminae in M³ (cf. seven in *O. angoniensis*, and four or five in *O. sloggetti*), allies this form with *O. angoniensis* (Taylor *et al.* 2004a) rather than with *O. tropicalis* as was previously thought. However, because of its very disjunct distribution, *O. burtoni* is here maintained as a distinct species following Musser & Carleton (2005). Synonyms: none. Chromosome number: not known.

Description Large, stoutly built rat with large, blunt head. Pelage long and soft (ca. 20 mm on mid-back). Dorsal pelage dull grizzled brown with a slight coppery tint. Hands and feet dark brown. Tail relatively short (50% of HB). Each upper and lower incisor with deep inner and shallow outer groove. M³ with six or seven laminae. M₁ with four laminae. Nasal bones moderately expanded. Petrotympanic foramen slit-like. Nipples: four.

Geographic Variation None recorded.

Similar Species

O. occidentalis. M³ with eight (occasionally seven) laminae; M₁ with five laminae; petrotympanic foramen slit-like (Dieterlen & Van der Straeten 1992).

O. angoniensis. M³ with seven laminae; petrotympanic foramen slit-like; not found in Cameroon.

Otomys burtoni

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from Mt Cameroon, Cameroon, and the only known species of *Otomys* on the mountain.

Habitat Montane wetlands. Type specimen was collected at 2100 m.

Abundance No information.

Remarks Apparently no other information available.

Conservation IUCN Category: Endangered.

Listed as Endangered because of restricted geographic range and degradation of wetland habitats by overgrazing.

Otomys cuanzensis CUANZA VLEI RAT

Fr. Rat du vlei de Cuanza ; Ger. Cuanza Lamellenzahnratte

Otomys cuanzensis Hill and Carter, 1937. Amer. Mus. Novit. 913: 7. Chitau, Angola. 4930 ft (1500 m).

Taxonomy Mistakenly treated as a synonym of *maximus* (= *angoniensis*) by Musser & Carleton (1993). The presence of six to seven laminae in M³, and a round petrotympanic foramen, indicates a closer relationship with either *O. irroratus* or *O. tropicalis*. Since *O. cuanzensis* differs clearly from *O. irroratus* in having much narrower nasal bones and a uniformly brown pelage, and from *O. tropicalis* in having six rather than seven laminae in M³, it is treated as a distinct species pending a definitive study of its specific relationships (Musser & Carleton 2005). Synonyms: none. Chromosome number: not known.

Description Large, stoutly built rat with large, blunt head and relatively short tail. Pelage moderately long, soft, fine and thick. Dorsal pelage brown mixed with iridescent black, general colour 'near Bister' (Hill & Carter 1937, 1941). Flanks with black overlay less evident. Ventral pelage paler, deep neutral grey overlaid with cinnamon-buff or even paler. Eyes without paler rings. Ears of medium length, well haired, somewhat paler than body. Limbs short. Tail relatively short (ca. 58% HB), bicoloured and paler below, with short bristles. Each upper incisor with single groove, each lower incisor with one deep groove and additional faint or very faint groove, occasionally absent. M³ with six or seven laminae. M₁ with four laminae. Nasal bones moderately expanded. Petrotympanic foramen round. Nipples: four.

Geographic Variation None recorded.

Similar Species May co-exist sympatrically with two other species of *Otomys* in Angola:

O. angoniensis maximus. M₁ with four laminae; petrotympanic foramen slit-like.

O. anchietae. M₁ with five or six laminae; HB, HF, M¹–M³ probably shorter.

Distribution Endemic to Africa. Zambezan Woodland BZ. Distribution coincides largely with the drainage of the Cuanza R. in NW Angola, and other rivers in the north of Angola, which empty

into the Atlantic Ocean. Although occurring sympatrically with *O. anchietae* at Chitau, and with *O. angoniensis maximus* at Mt Soque, its geographic range appears to be parapatric to those of the other two Angolan species.

Habitat No information.

Abundance No information.

Remarks Apparently no other information available. Presumably similar to *Otomys irroratus*.

Conservation IUCN Category: Least Concern.

Measurements*Otomys cuanzensis*

Angola (Hill & Carter 1941)

Key References Crawford-Cabral 1998; Hill & Carter 1937, 1941.**P. J. Taylor***Otomys denti* DENT'S VLEI RAT

Fr. Rat du vlei de Dent; Ger. Dents Lamellenzahnratte

Otomys denti Thomas, 1906. Ann. Mag. Nat. Hist., ser. 7, 18: 142. Mabuku Valley, east slope of Mt Rwenzori, Uganda.**Taxonomy** Synonyms: *kempi*, *sungae*. Subspecies: none. Chromosome number: not known.**Description** Large, stoutly built rat with large, blunt head. Pelage soft, fine and thick. Slightly smaller than *O. tropicalis*. Dorsal pelage dark blackish-brown with coppery tinge (distinctly different to other *Otomys* spp.). Ventral pelage similar to dorsal pelage. Tail short (54% of HB), black above and below (all other *Otomys* spp. have bicoloured tails). Each upper and lower incisor with single groove. M³ with five or six laminae. M₁ with four laminae. Nasal bones moderately expanded. Petrotympanic foramen round. Nipples: 0 + 2 = 4.**Geographic Variation** None recorded.**Similar Species***O. saundersiae*. Dorsal pelage paler, tail bicoloured, endemic to South Africa.*O. tropicalis*. Dorsal pelage paler, tail bicoloured, M³ with more than six laminae.*O. angoniensis*. Dorsal pelage paler, tail bicoloured, slit-like petrotympanic foramen.*O. sloggetti*. Dorsal pelage paler, tail bicoloured, slit-like petrotympanic foramen, endemic to South Africa.*O. anchietae*, *O. occidentalis*, *O. barbouri*, *O. lacustris*. M₁ with five laminae.**Distribution** Endemic to Africa. Afroalpine–Afroalpine BZ. Disjunct distribution on widely separated mountain ranges. Recorded from Uganda and DR Congo (Rwenzori and Albertine Rift Valley Mountains), EC Tanzania (Usambara and Uluguru Mts), N Malawi (Nyika Plateau) and extreme E Zambia. Based on widespread occurrence of fossils during the Pleistocene, historical distribution was much more widespread. On Rwenzori Mts, altitudinal range is 1860–3900 m (eastern side) and 2100–2700 m (western side) (J. Kerbis unpubl.).**Habitat** Damp montane grasslands and *Protea* scrub (Malawi; Ansell & Dowsett 1988) and secondary growth associated with forests in east-central Africa (Kingdon 1974). On Nyika Plateau, Malawi, mostly found near water and on swampy ground (Hanney 1965).**Abundance** No information.**Adaptations** Apparently more specialized than *O. tropicalis*. The two species only occur together in diversified habitats, but *O. denti* tends to displace *O. tropicalis* in montane situations, e.g. the earliest collecting records in the Rwenzori Mts show that *O. tropicalis* was the dominant species, but by the early 1960s it had been replaced by *O. denti* (Misonne 1963, Rahm 1967).**Foraging and Food** Presumably herbivorous as for other members of the genus. According to Kingdon (1974), individuals of this species have been reported to damage cypress trees, eating the bark and cambium of trees 1–8 years old.**Social and Reproductive Behaviour** No information.**Reproduction and Population Structure** In Malawi, pregnant ♀♀ recorded during the cool dry season (May, Jun and Nov). Embryo number: 1 (n = 4), 4 (n = 1) (Hanney 1965).*Otomys denti*

Predators, Parasites and Diseases Remains have been found in the stomach of a the Pallid Harrier *Circus macrourus* and an African Grass-owl *Tyto capensis* as well as comprising the bulk of the faeces of a leopard (Lawrence & Loveridge 1953).

Conservation IUCN Category: Least Concern.

Otomys irroratus SOUTHERN AFRICAN VLEI RAT

Fr. Rat du vlei d’Afrique du Sud; Ger. Gemeine Lamellenzahnratte

Otomys irroratus (Brants, 1827). Het Geslacht der Muizen, p. 94. Constantia, Cape Town, Western Cape Province, South Africa.

Taxonomy Originally described in the genus *Euryotis*. Some authors have included *Otomys tropicalis* in *Otomys irroratus* (Bohmann 1952, Petter 1982, Dieterlen & Van der Straeten 1992), but Misonne (1974) and Musser & Carleton (1993, 2005) regarded each as separate species. On morphometric grounds, the two species are distinct (Taylor & Kumirai 2001). Meester *et al.* (1986) recognized eight subspecies, but none is currently recognized. Synonyms: *auratus*, *bisulcatus*, *capensis*, *coensus*, *cupreoides*, *cupreus*, *natalensis*, *obscura*, *orientalis*, *randensis*, *typicus*. Subspecies: none recognized here (but see below). Chromosome numbers: 2n = 23–32, aFN = 24–50.

The species has undergone major karyotypic evolution when compared with its congeners (Robinson & Elder 1987). Five parapatric ecologically distinct but genetically similar cytotypes are recognized: A, A1, A2, B and C (Contrafatto *et al.* 1992b, c, Taylor *et al.* 1992, 1993a, Contrafatto 1996, Taylor 2000). Cytotypes differ in the morphology of the seven largest chromosome pairs: all are single-armed (acrocentric) in A, A1 and A2, four pairs are biarmed or submetacentric in C (due to addition of heterochromatic whole arms), and all are submetacentric in B. Cytotype A2 bears two additional unidentified chromosome pairs not found in other cytotypes. Populations of cytotype A1 are reproductively isolated from other populations due to a complex tandem fusion rearrangement involving chromosome pairs 7 and 12 (Contrafatto *et al.* 1992b, Contrafatto 1996, Rambau *et al.* 2001). In all cytotypes, numerical variation (from 0 to 4) occurs between the number of small variable-morphology B-chromosomes (Contrafatto *et al.* 1992b). See also ‘Geographic Variation’ and ‘Social and Reproductive Behaviour’ below.

Description Large stocky rat with dense shaggy pelage. Dorsal pelage varies in colour geographically from dark slatey-greyish buff or ‘olive-brown’ with black-tipped hairs (KwaZulu–Natal Province) to a richer buffy or ‘cinnamon-brown’ with buffy-tipped hairs (Eastern Cape and Free State Provinces). Ventral pelage dark grey to paler greyish-buffy. Large head. Small well-haired ears held close to head. Tail short (ca. 60% of HB). Each upper and lower incisor with

single groove, although a shallow inner groove is additionally present in each lower incisor. M³ with six laminae (very occasionally seven). M₁ with four laminae. Nasal bones sharply expanded. Petrotympenic foramen round and large. Nipples: not known.

Geographic Variation Five cytotypes of indeterminate evolutionary status are recognized:

Cytotype A: lower altitudes (<1400 m) from C KwaZulu–Natal to Eastern Cape Province, South Africa.

Cytotype A1: Drakensberg mountain slopes (ca. 1400–1800 m) from KwaZulu–Natal to Eastern Cape Province, South Africa.

Cytotype A2: central mistbelt of KwaZulu–Natal, South Africa, 1000–1400 m.

Cytotype B: South Africa (lower-lying region of Eastern Cape Province from Grahamstown to Port Elizabeth and Fish River Valley) and Zimbabwe.

Cytotype C: winter-rainfall region of Western Cape Province, and highveld of Free State and Gauteng Provinces, South Africa.

According to Rambau *et al.* (2001), only two cytotype-groups should be recognized: A1 (with the composite chromosomal rearrangement), and all other cytotypes lacking this rearrangement. However, Taylor *et al.* (2009b) and Engelbrecht *et al.* (2011) recognize, on molecular and morphological grounds, two evolutionary lineages (species), which correspond with bioregions rather than karyotype, these being *irroratus* s.s. (from fynbos and thicket biomes) and *auratus* (from high-lying grasslands).

Similar Species

O. angoniensis. M³ with seven laminae; petrotympanic foramen slit-like; distribution in South Africa mostly <1000 m in savanna habitats, therefore largely parapatric with *O. irroratus* (>1000 m, highland grasslands).

O. laminatus. M³ with eight to ten laminae; M₁ with seven laminae; narrow distribution in South Africa, sympatric with *O. irroratus*.

*Otomys irroratus*

O. saundersiae. M³ with five to seven laminae; paler colour and smaller size; rocky hillside habitats in fynbos and thicket biomes of Western and Eastern Cape Provinces.

O. tropicalis. M³ with seven or more laminae; East and central Africa.

O. cuanzensis. M³ with seven laminae; restricted to Angola.

Distribution Endemic to Africa. Highveld and South-West Cape BZs and montane habitats of South Africa and Zimbabwe; extends marginally into southern parts of South-West Arid BZ. Recorded in South Africa from Cape Town to E KwaZulu–Natal and the central highveld of Gauteng Province; isolated populations are present in the southern parts of South-West Arid BZ at Kuruman (Northern Province) and into the Karoo along the Fish River Valley. Also recorded from Lesotho and Swaziland, and from E Zimbabwe and adjacent parts of W Mozambique. Altitudinal range is sea level to 2400 m.

Habitat Montane and sub-montane grasslands, fynbos and heath habitats. May occur in great abundance in rank grassy verges and overgrown garden lawns. Populations are mostly continuous in montane, high-rainfall areas, but disjunct at lower altitudes where they occur in areas of lush grass, sedge and herbs on damp wetland soils.

Abundance Abundant in suitable habitats. In a population near Pretoria, density increased from 17/ha in Sep to 72/ha in May. Mean density throughout year was 36/ha (Davis 1973).

Adaptations Mainly crepuscular. Creates distinctive 'runways' in the grass, which are used by other species of small mammals. The gut is modified for specialized herbivory: e.g. the stomach is U-shaped with an oesophageal sac capable of tremendous expansion, and the caecum is large and complex with a mean length of 149 mm (Davis 1973). Digestion of vegetation relies greatly on caecal fermentation. Coprophagy common.

Foraging and Food Diet is only green plant material with a fairly stable nutrient content (Perrin 1980a). Preferred food plants include stems and leaves of palatable grasses (e.g. *Panicum* spp.) and herbs. May feed on the soft outer bark of pine trees in forestry plantations and may cause extensive damage. Piles of discarded stems and leaves of grasses betray the location of their feeding spots along the runways.

Social and Reproductive Behaviour Solitary and aggressive. Levels of aggression are greatest in scrotal ♂♂, and decline successively from perforate ♀♀ to non-scrotal ♂♂ to imperforate ♀♀. Mean home-range 1730 m² in males and 1252 m² in females (Davis 1973). Adults partly territorial, defending a small area around the nest. Intraspecific conflict is minimized by anal-gland marking and indiscriminate urination and defecation along runways. Individual encounters are characterized by nose–nose contact with the body held low and extended, threat displays and by chases and fights, which may result in serious wounds. Submissive individuals rear upright with the forelimbs extended, exposing the vulnerable belly, and vocalize with a soft chittering (Davis 1972). In captivity, male–female aggression is high at initial contact, but declines over about four days, after which mating occurs. When individuals of particular cytotypes were paired, there was delayed mating due to heightened aggression, as well as significant ♀ choice of homotypes over heterotypes (Pillay *et al.* 1995b). Reproduction between different cytotypes resulted in 96% loss of fertility in hybrids (Pillay *et al.* 1995a).

Reproduction and Population Structure Gestation: 5–6 weeks. Females polyoestrus; 3–4 births/year. Near Pretoria, reproduction declined in mid-winter (Jun, Jul) but resumed in Aug following an increase in daylength and before there was an increase in food quality and quantity (Davis & Meester 1981). In Eastern Cape Province, reproduction declined in mid-summer, and was linked to a reduction in food availability rather than to variations in rainfall (Perrin 1980b). Mean litter-size: 1.5 in Eastern Cape Province (Perrin 1980b), 1.6 in Drakensberg Mts (Rowe-Rowe & Meester 1982b), 2.8 near Pretoria (Davis & Meester 1981); range (at all locations): 1–4. At birth, weight 12.5 g; incisors erupted. Young nipple-cling immediately after birth. Growth rapid: adult behaviour patterns attained at two weeks; 71% of adult weight attained in ten weeks; sexual maturity reached at 96 g (ten weeks for ♀♀ and 14 weeks for ♂♂) (Davis & Meester 1981). Greatest longevity in captivity: 22 months (Davis 1973).

Predators, Parasites and Diseases Bronner *et al.* (1988) list 21 known predator species, including humans, snakes (e.g. python *Python sebae* and Mole Snake *Pseudaspis cana*), birds (e.g. Grey Heron *Ardea cinerea*, and four species of owls), and mammalian carnivores (e.g. Serval *Felis serval*, Wild Cat *Felis lybica* and genet *Genetta* spp.). *Otomys irroratus* is typically by far the commonest prey item found in owl pellets and in faeces of Servals (Davis 1973, Bowland & Perrin 1983). Bronner *et al.* (1988) list 63 species of parasites (e.g. nematodes, cestodes, trematodes, mites, fleas, ticks and lice), and at least four zoonoses for which this species is probably a reservoir (bluetongue virus, bubonic plague, tick-bite fever and Q-fever).

Conservation IUCN Category: Least Concern.

Otomys lacustris LAKE VLEI RAT

Fr. Rat du vlei du lac; Ger. Wasser-Lamellenzahnratte

Otomys lacustris Allen and Loveridge, 1933. Bull. Mus. Comp. Zool. Harvard 75: 120. Madehani, Ukinga Mts, Tanzania.

Taxonomy Lawrence & Loveridge (1953) described *lacustris* as a subspecies of *O. anchietae*, an arrangement followed by Bohmann (1952). Musser & Carleton (1993) placed *lacustris* as a synonym of *O. anchietae*. Recognized as a valid species by Dieterlen & Van der Straeten (1992) on the basis of morphometrics and cranial variables, and by Taylor & Kumirai (2001) on the basis of PCA and discriminant functions analysis of 16 cranial variables. Synonyms: none. Chromosome number: not known.

Description Large with comparatively long tail and very dark pelage. Pelage smoother and less brightly coloured than other species of *Otomys*. Dorsal pelage dark blackish-brown, hairs black or brown at base with narrow rusty subterminal band and black tip. Flanks dark brown. Ventral pelage paler. Tail comparatively long (ca. 65% of HB). Each upper and lower incisor with one single groove. M³ with six (occasionally seven) laminae; M₁ with five laminae. Nasal bones moderately expanded. Petrotympanic foramen round. Nipples: 0 + 2 = 4.

Geographic Variation None recorded.

Similar Species

Otomys anchietae. Much larger (HB: >187 mm); M³ with six (occasionally seven) laminae; M₁ with five (occasionally six) laminae; Angola only.

O. barbouri. Tail shorter (ca. 45% of HB); M³ with seven (occasionally eight) laminae; Mt Elgon only.

O. typus. Each lower incisor with two grooves; M³ with seven laminae, M₁ with four laminae; Afromontane–Afroalpine BZ of eastern Africa; sympatric at some localities.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of eastern Africa. Recorded from Kenya (one dubious record from the Aberdare Mts), Malawi (Mugesse Forest, as *O. anchietae*), Zambia (Abercorn = Mbala) and Tanzania (Ukinga Mts, Poroto Mts, Ufipa Plateau, Uzungwe Mts and Ilolo). The Kenya specimen clustered with *O. lacustris* (Taylor & Kumirai 2001).

Otomys lacustris

Habitat Montane habitats. Found in wet forest close to small stream (Mugesse Forest, Malawi); and in 'forest' on Ufipa Plateau, Tanzania (Dieterlen & Van der Straeten 1992). Detailed descriptions of habitat are lacking. The dubious record from Kenya (see above) was obtained in afroalpine habitat.

Abundance Uncertain. Rare in collections.

Remarks Apparently no other information available. See genus profile.

Conservation IUCN Category: Vulnerable.
Restricted to mountain ranges in eastern Africa.

Key References Allen & Loveridge 1933; Dieterlen & Van der Straeten 1992; Taylor & Kumirai 2001.**Viola Clausnitzer*****Otomys laminatus* LAMINATE VLEI RAT (KWAZULU VLEI RAT)**

Fr. Rat du vleï laminé; Ger. Kap-Lamellenzahnratte

Otomys laminatus Thomas and Schwann, 1905. Abstr. Proc. Zool. Soc. Lond. 1905 (18): 23. Sibhudeni, Nkandhla Forest, KwaZulu–Natal, South Africa. 1050 m.**Taxonomy** Thomas (1918) erected a subgenus *Lamotomys* for this species, which was raised to generic rank by Roberts (1951), a view not currently followed. Synonyms: *fannini*, *mariepsi*, *pondoensis*, *silberbaueri*. Subspecies: five were recognized by Roberts, but Meester *et al.* (1986) consider it more likely that the four eastern forms are synonymous with the nominate form. Chromosome number: not known.**Description** Medium-sized, heavy-set rat with short tail. Pelage soft and shaggy; hairs ca. 20 mm. Dorsal pelage dark buffy-brown or 'raw umber'; hairs black at base with subterminal brown band and black tip. Indistinguishable from darker individuals of *Otomys irroratus*. Ventral pelage dull yellowish; hairs grey at base. Throat dull yellowish-white. Ears naked. Tail short (ca. 57% of HB), well haired, blackish above and dull buffy below. Each upper and lower incisor with single deep groove, with additional inner shallow groove ineach lower incisor. M³ with 8–10 laminae, usually nine, and distinctively more than any other species of *Otomys*. M₁ with seven laminae, also exceeding the number for any other *Otomys*. Nasal bones sharply expanded. Petrotympanic foramen round. Sexual dimorphism in some body measurements. Nipples: four.**Geographic Variation** None recognized here.**Similar Species***O. irroratus*. M³ with 6–7 laminae.*O. angoniensis*. M³ with 6–7 laminae; petrotympanic foramen slit-like.**Distribution** Endemic to Africa. Afromontane–Afroalpine and Highveld BZs; sometimes in parts of Coastal Forest Mosaic BZ. Recorded only in South Africa. Occurs along eastern foothills of Drakensberg range from Eastern Cape Province through KwaZulu–Natal into Mpumalanga Province, with a relic population in the Cape Peninsula and Paarl Valley of Western Cape Province.**Habitat** Mesic sub-montane grasslands along the Drakensberg foothills in KwaZulu–Natal, also recorded from coastal forests in KwaZulu–Natal, and from *Restio*-dominated coastal fynbos and mountain fynbos habitats in the Western Cape Province (De Graaff 1981, Taylor *et al.* 1994, Taylor 1998). May occur in pine plantations.**Abundance** Much less common than *O. irroratus*, with which it shares the same habitats. Occasionally common, e.g. *O. laminatus* was the only species of *Otomys* trapped in a single pine plantation (n = 56; P. J. Taylor unpubl.).**Remarks** As described for *O. irroratus*. Since increasing laminae number is surmised to be associated with an evolutionary trend towards increased specialization to mesic habitats (Pocock 1976, Denys 1989b), this species is presumably the most specialized species of *Otomys* in this respect. Probably entirely vegetarian, feeding on shoots and stems of grasses, *Restio* and small shrubs (De Graaff 1981).**Conservation** IUCN Category: Least Concern.

Otomys occidentalis WESTERN VLEI RAT

Fr. Rat du vlei occidental; Ger. Westliche Lamellenzahnratte

Otomys occidentalis Dieterlen and Van der Straeten, 1992. Bonn. Zool. Beitr. 43: 386. Chappal Waddi, Gotel Mts, south-east Nigeria.

Taxonomy Closely related to *O. anchietae*, *O. lacustris* and *O. barbouri* in having five laminae in M₁. Synonyms: none. Chromosome number: not known.

Description Medium-sized, stoutly built rat, but one of the smallest species of the genus (see also *O. saundersiae*). Pelage soft, fine and thick; hairs 20–27 mm. Dorsal pelage brown to blackish-brown, slightly more reddish in individuals from Mt Oku than those from Gotel Mts. Flanks slightly paler; hairs with yellowish tip. Ventral pelage blackish-grey, silky and glossy (more so than dorsal pelage); individuals from Mt Oku paler and more brownish than those from Gotel Mts. Head large and blunt. Tail short (ca. 54% of HB) and bicoloured. Each upper and lower incisor with single groove. Nasal bones sharply expanded. M³ with eight, occasionally seven, laminae. M₁ with five laminae. Petrotympanic foramen slit-like (n = 1). Nipples: 0 + 2 = 4.

Geographic Variation None recorded.

Similar Species

O. burtoni. Mean values for measurements slightly larger; pelage paler and more buffy; M³ with six or seven laminae; M₁ with four laminae; petrotympanic foramen round; Mt Cameroon only.
O. barbouri. HB on average larger, M³ with seven to eight laminae; petrotympanic foramen round; longer dorsal hairs 20–35 mm; Mt Elgon only.

Distribution Endemic to Africa. Afroalpine–Afroalpine BZ in Nigeria and Cameroon. Known from only two localities: Mt Oku (2100–3000 m) in W Cameroon and Gotel Mts (1900–2300 m) in E Nigeria.

Habitat Alpine heath and grassland with ferns in montane forest clearings, 1900–3000 m (Dieterlen & Van der Straeten 1992).

Abundance No information.

Remarks One ♀ with two embryos was collected in Mar (Dieterlen & Van der Straeten 1992).

Conservation IUCN Category: Vulnerable.

The restricted geographic range and continuing decline in area, extent and quality of its montane habitat are cause for concern.

Otomys saundersiae SAUNDERS'S VLEI RAT

Fr. Rat du vlei de Saunders; Ger. Saunders Lamellenzahnratte

Otomys saundersiae Roberts, 1929. Ann. Transvaal Mus. 13: 115. Grahamstown, Eastern Cape Province, South Africa.

Taxonomy *Otomys saundersiae* is retained as a valid species here, although Musser & Carleton (2005) regard *saundersiae* as a subspecies of *O. irroratus*. *Otomys saundersiae* is distinct from *O. irroratus* on the basis of consistent but subtle differences in chromosomal, allozyme, DNA (PCR–RAPD), pelage colour and/or morphometric characters (Meester *et al.* 1986, Taylor *et al.* 1993b, 2005). Synonyms: *karoensis*. Subspecies: two, but both may prove to deserve specific status. Chromosome number: $2n = 28$, $aFN = 42$ – 44 (Taylor 2000, Taylor *et al.* 2005).

Description Medium-sized stocky rat. Pelage dense and shaggy, 13–16 mm on mid-back. Dorsal and ventral pelage variable – see Geographic Variation. Head large. Small well-haired ears held close to head. Tail bicoloured, short (ca. 73% of HB), but relatively longer than other *Otomys* spp. Each upper and lower incisor with single deep groove; additional inner shallow groove on each lower incisor. M^3 with six, sometimes five, laminae (although seven in holotype). M_1 with four laminae. Nasal bones moderately expanded (Taylor *et al.* 1993b). Petrotympanic foramen round. Nipples: $0 + 2 = 4$.

Geographic Variation

O. s. saundersiae: coastal and low-lying parts of the Eastern Cape Province, south of 33°S. On average slightly larger, intermediate between *O. irroratus* and *O. s. karoensis*; dorsal pelage pale buffy, speckled with dark brown-tipped hairs; dorsal hairs 13 mm; flanks paler buffy; ventral pelage grey; throat and distal appendages whiter in colour; tail buffy-white dorsally, grey below; tip of muzzle, ring around eye and tuft of hair in front of the ears buffy-yellow; hair immediately behind ears buffy to white.

O. s. karoensis: mountainous areas of the Western and Eastern Cape Provinces and extreme SW Free State. Dorsal pelage pallid greyish-buffy, conspicuously paler than in *O. irroratus* but less buffy than in *O. s. saundersiae*; dorsal hairs generally 16 mm, pencilled with black due to numerous interspersed longer (26 mm) black-tipped hairs; ventral pelage less buffy-grey.

Similar Species

O. irroratus. Body size on average larger; GLS on average larger; pelage darker; M^3 with six to seven laminae; upper incisor with single groove; nasal bones widen more abruptly anteriorly.

O. unisulcatus, *O. sloggetti*, *Parotomys brantsii*, *P. littledalei*. Pelage paler; lower incisors ungrooved; not found in winter rainfall region of Western Cape Province.

Otomys saundersiae

Distribution Endemic to Africa. South-West Cape BZ and Highveld BZ. *Otomys s. saundersiae* confined to coastal and low-lying areas of the Eastern Cape Province, South Africa, south of 32°S from King William's Town in the east to Port Elizabeth in the west, possibly as far west as the Bredasdorp area. *Otomys s. karoensis* occupies two separate areas: (1) mountainous winter rainfall areas of Western Cape Province, from the Cape Peninsula north to the Citrusdal district; and (2) summer rainfall areas of southern portion of the Drakensberg range in Eastern Cape Province (north of 32°S and west of Lesotho), and into Free State where it has been recorded in the Bloemfontein district (Taylor *et al.* 2005).

Habitat *Otomys s. saundersiae* prefers open grassland habitats on the drier upper slopes in hilly terrain. *Otomys s. karoensis* prefers rocky mountain fynbos habitats on the upper mountain slopes where *Restio* is a dominant species; exceptionally *O. s. karoensis* has been found in open grassland and scrubland in the Bloemfontein and Fauresmith districts of SW Free State (Taylor *et al.* 2005).

Abundance Based on the proportionately fewer numbers of museum specimens, and difficulty in trapping them, *O. s. saundersiae* is much less common than *Otomys irroratus* in Eastern Cape Province.

Otomys s. karoensis may be easily trapped in fair numbers in mountainous habitats in Western Cape Province (P. J. Taylor unpubl.).

Remarks In captivity, individuals of *O. s. karoensis* are docile and curious, contrasting with the typical aggressive and shy behaviour of *O. irroratus* (A. Kumirai & P. J. Taylor unpubl.). Three species of laelaptid mites, four species of fleas (of the families Hystrichopsyllidae and Chimaeropsyllidae) and four species of ticks (one species of soft tick and three species of hard ticks) have been described (De Graaff 1981).

Conservation IUCN Category: Least Concern.

In 1996, listed as Near Threatened.

Otomys sloggetti SLOGGETT'S VLEI RAT

Fr. Rat du vlei de Sloggett; Ger. Sloggetts Lamellenzahnratte

Otomys sloggetti Thomas, 1902. Ann. Mag. Nat. Hist., ser. 7, 10: 311. Deelfontein, Northern Cape, South Africa.

Taxonomy Closely related to *O. unisulcatus* (Thomas 1918, Roberts 1951, Taylor *et al.* 1989) but not as sister species (Taylor *et al.* 2004a). Placed in the genus *Myotomys* by Musser & Carleton (2005). Synonyms: *basuticus*, *jeppiei*, *robertsi*, *turneri*. Subspecies: five. Chromosome number: 2n = 42, aFN = 48, comprising 16 acrocentric, two metacentric and two subtelocentric pairs, a medium-sized acrocentric X-chromosome and a small acrocentric Y-chromosome (Contrafatto *et al.* 1992a). Allozyme data show reduced gene flow between high altitude populations of *O. s. robertsi* from north Eastern Cape and NE Lesotho (Contrafatto *et al.* 1992a).

Description Medium-sized, stoutly built rat. Pelage soft, fine and thick. Dorsal pelage pale greyish-buffy. Flanks pale greyish-brown. Ventral pelage whitish-buffy. Large blunt head. Area around facial vibrissae red-brown, a character that can be used to distinguish this species from other *Otomys* spp. Ears small, dark on posterior edge. Tail short (ca. 49% of HB), bicoloured, black above, pale buffy below. Each upper incisor with one groove; each lower incisor with one very faint groove. M³ with four or five laminae, M₁ with four laminae. Nasal bones barely expanded. Petrotympanic foramen slit-like. Anterior expansion of nasal bones makes an obtuse angle (ca. 150 degrees). Nipples: 2 + 0 = 4.

Geographic Variation Five subspecies recognized but with poorly defined geographical boundaries:

O. s. sloggetti: Northern Cape Province, South Africa.

O. s. turneri: E Free State Province, South Africa.

O. s. robertsi (Ice Rat): high Drakensberg Mts in Lesotho and N Eastern Cape Province, South Africa.

O. s. jeppiei: Northern Cape Province, South Africa.

O. s. basuticus: low-lying parts of SE Lesotho.

Similar Species

O. unisulcatus. M³ with six or five laminae; petrotympanic foramen round; semi-arid habitats.

O. saundersiae. Dorsal pelage less pallid; M³ with six (rarely five or seven) laminae; petrotympanic foramen round; winter rainfall biome of Western and Eastern Cape Provinces.

Distribution Endemic to Africa. Highveld BZ and Afroalpine BZ of South Africa and Lesotho. Recorded throughout the high Drakensberg Mts, South Africa (i.e. the western border of KwaZulu–Natal, NE Free State, Eastern Cape Provinces) and Lesotho, to about 27°S in Mpumalanga Province (only at Wakkerstroom). Isolated relict populations in the Karoo near Hanover, Orange R., and as far west as Deelfontein in Northern Cape Province (De Graaff 1981, Lynch 1983, 1989, Lynch & Watson 1992, P. J. Taylor unpubl.). It is likely that this species previously occupied a much wider distribution, and range of altitudes and habitats, as evidenced by its presence in late Holocene sites (<1000 years ago) in the upper Tugela River basin in KwaZulu–Natal, which are now covered by savanna (Avery 1991). Altitudinal range: above 2000 m (most of range) and above 2600 m in Lesotho (Rowe-Rowe & Meester 1982b, Lynch 1994).

*Otomys sloggetti*

Habitat Montane and alpine grasslands on xeric or mesic soils, with or without rocky outcrops. Typically individuals live in piles of loose stones and boulders, both natural and man-made (e.g. stone walls throughout Lesotho). In boggy situations, these vlei rats construct their burrows on raised hummocks, which they create by their own burrowing activities (Lynch & Watson 1992). In the Drakensberg Mts of the KwaZulu–Natal, burrows maybe found in alluvial soils along river banks (D. Rowe-Rowe pers. comm.). Isolated populations occupy dry semi-desert habitats in the eastern Karoo, but these recorded localities are in the vicinity of inselbergs and mountain ranges at >1500 m.

Abundance Densities of over 100/ha have been estimated in suitable rocky habitats (Willan 1990).

Adaptations Diurnal. Individuals sun themselves on exposed rocks (or at the entrance to burrows) intermittently throughout the day to gain heat. Burrow-dwelling, and hoarding of food in burrows, may be adaptations for surviving periods of intense cold. Such behaviour may facilitate the *ad libitum* suckling of young by lactating ♀♀, and thereby delay emergence of young from the nest until about five weeks of age. Survival of young is thus enhanced by greater protection from predators, and by postnatal development of thermoregulatory ability necessary to cope with cold temperatures. Reduced length of HB and extremities (tail, hindfoot and ear) of young Ice Rats (*O. sloggetti robertsi*), compared to young *O. irroratus*, is also a thermoregulatory adaptation to reduce surface area/volume ratios and to minimize heat loss in intensely cold environments (Willan 1990). Similarly, adults have significantly shorter tails than other *Otomys* spp. (Richter 1997). Adults are best able to thermoregulate at lower, rather than higher, temperatures compared to other *Otomys* spp., which might explain their restriction to higher altitudes and cold habitats (Richter *et al.* 1997).

As with other species of *Otomys* and *Parotomys*, the structure of the gut is adapted to a high fibre diet. The slightly larger size of the small intestine, caecum, stomach and parts of the colon in the Ice Rat (*O.*

sloggetti robertsi) compared with other species of Otomyinae could be an adaptation for increased energy uptake and/or poor diet quality in alpine environments. The dimensions of the gut of female Ice Rats increase during summer, possibly in response to the increased energy requirements of lactation and pregnancy (Schwaibold & Pillay 2003).

Foraging and Food Specialist herbivore, feeding on stems, leaves and floral parts of a range of green plants. Food plants are hoarded in burrows, including *Knopfia caulescens*, *Cyperus* spp., *Eumorphia sericea*, *Anthraxia fontana*, *Euryops* sp., *Arctotis arctoides*, *Selago flanaganii*, *Senecio asperulus* and two grass species, *Bromus* sp. and *Vulpia bromoides*. Foraging is usually limited to regions in close proximity to burrow entrances (Hinze *et al.* 2003). In summer, food is mostly eaten *in situ*. In contrast, in winter, food is usually carried back to the burrow thus avoiding long exposure to extreme cold temperatures and, possibly, helping to avoid injury due to aggressive competition when food resources are limited (Schwaibold & Pillay 2003).

Social and Reproductive Behaviour Burrows may be occupied by pairs or family groups within which only a single pair breeds (Willan 1990). Burrows comprise an intricate tunnel system, usually 200–300 mm deep, with one or two active nest sites lined with finely shredded grass leaves, and 2–12 tunnel entrances. Faeces are deposited at or just inside tunnel entrances (Lynch & Watson 1992, Hinze *et al.* 2003).

Sociality in Ice Rats *O. s. sloggetti* varies spatially and seasonally. When above ground, individuals of a group are partly territorial, maintaining overlapping home-ranges and competing aggressively for limited food resources between themselves as well as against non-group members (Hinze *et al.* 2003). One or more sentinels apparently maintain vigilance for the group. When underground, individuals huddle to conserve heat and there is no evidence of territoriality. Groups comprise 4–16 individuals. Individuals of a group make synchronized above-ground appearances each day, but do not follow generalized behaviour patterns. They are active throughout the year, although in winter they spend more time each day underground in their burrows. Individuals are highly inquisitive and relatively unafraid of humans (Hinze *et al.* 2003).

Reproduction and Population Structure Pregnancies recorded during mid- to late summer (Oct–Mar) in Lesotho. Mean litter-size: 2.5 (2–5; Lynch 1994). In captivity, gestation 38 days, litter-size 1.4 (1–2), reproductive effort 0.5, and fecundity about six young/annum (Willan 1990).

Predators, Parasites and Diseases Predators include Small Grey Mongooses *Galerella pulverulenta*, Barn Owls *Tyto alba*, Steppe Buzzards *Buteo buteo* and Jackal Buzzards *B. rufofuscus*. Mites (two species), fleas (11 species) and ticks (two species) have been recorded (details in De Graaff 1981).

Conservation IUCN Category: Least Concern.

Otomys tropicalis TROPICAL VLEI RAT (EAST AFRICAN VLEI RAT)

Fr. Rat du vlei du tropique; Ger. Tropische Lamellenzahnratte

Otomys tropicalis Thomas, 1902. Ann. Mag. Nat. Hist., ser. 7, 10: 314. West slope of Mt Kenya, Kenya. 10,000 ft (3000 m).

Taxonomy Although regarded by some authors to be conspecific with *O. irroratus* (Misonne 1974, Petter 1982, Dieterlen & Van der Straeten 1992), this species has been shown to be distinct on morphometric and dental evidence (Taylor & Kumirai 2001, Taylor *et al.* 2004b). Musser & Carleton (2005) consider *dollmani* and *orestes* from Kenya (here retained as synonyms) to be valid species, distinct from *O. tropicalis* in pelage and skull-shape characters and in having six laminae on M³. Because it possesses a slit-like petrotympanic foramen (Taylor *et al.* 2004a), *burtoni* from Cameroon, previously considered to be a subspecies of *tropicalis* (Dieterlen & Van Straeten 1992), is here considered to be a distinct species. Synonyms (of *tropicalis*): *elgonis*, *dollmani*, *faradjius*, *ghighi*, *giloensis*, *orestes*, *nubilis*, *rubeculus*, *vivax*, *vulcanis* (of *orestes*): *malleus*, *percivali*, *thomasi*, *squalus*, *zinki*. Subspecies: uncertain; several have been described but their validity remains to be tested. Chromosome number: not known.

Description Large, stoutly built rat with large, blunt head and short tail. Pelage soft, fine and thick. Dorsal pelage dark brown, close to 'raw umber'. Flanks clear brown. Ventral pelage slatey, hairs buffy at tip. Eyes without paler rings. Ears of medium length, well haired, somewhat paler than body. Tail short (ca. 46% of HB), black above, dull white below. Each upper incisor with single groove; each lower incisor with one deep groove and additional faint or very faint groove (occasionally absent). M³ with seven (usually) or eight laminae. M₁ with four laminae. Nasal bones moderately expanded. Petrotympanic foramen round. Nipples: 0 + 2 = 4.

Geographic Variation Disjunct populations associated with different mountain ranges vary slightly in pelage colour, size and cranial characters (shape of nasal bones and the number of laminae on M³), making it difficult to delineate species or subspecies (although *orestes* and *dollmani* mentioned above may prove to represent distinct species coexisting with contiguous populations of *tropicalis* on the slopes of Mt Kenya).

Similar Species Four other species of *Otomys* occur in eastern Africa, but at higher altitudes than *O. tropicalis*:

- O. typus*. M³ with eight (sometimes six, seven or nine) laminae; two deep grooves on each lower incisor.
- O. barbouri*. M₁ with five laminae.
- O. lacustris*. M³ with six laminae; M₁ with five laminae.

O. denti. Much blacker pelage, tail not bicoloured, M³ with five or six laminae; M₁ with four laminae.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ in eastern Africa, and some nearby areas at lower altitudes. Recorded from E DR Congo, Uganda, Rwanda, Burundi, S Sudan, W and N Kenya and possibly NE Tanzania. Specific localities are Rwenzori Mts, Mt Elgon, Mt Kenya, Aberdare Ranges and Imatong Mts. One isolated record from Nyika Plateau, Malawi. Also occurs at lower altitudes such as Kampala in Uganda, and Garamba N. P. in NE DR Congo. Specimens from Mt Kilimanjaro and Msinga (NE Tanzania) are probably this species. Misonne's comment (1963) that *O. tropicalis* does not occur on the Rwenzori Mts is incorrect. Altitudinal range is very varied, from below 1000 m to over 3000 m; on Rwenzori Mts, range is ca. 840–2250 m.

Habitat Occupies a wide range of dense, moist grassland and scrub habitats, ranging from savanna to alpine heath, as well as cultivated areas (e.g. coffee and banana plantations). Avoids natural forested habitats except where these are highly degraded or where clearings and secondary growth are formed as a result of fire or destruction of the forest

Otomys tropicalis

(Verheyen & Verschuren 1966, Dieterlen & Van der Straeten 1992); also avoids very dry and permanently flooded marsh habitats (Misonne 1963). Not recorded in local houses. Sympatric with *O. denti* and *O. typus* in Rwenzori Mts, but each species has a different altitudinal range.

Abundance Common. In Haut Ituri, DR Congo, abundance varied according to habitat. Comprised ca. 40% of all small rodents in preferred habitats; estimated densities ranged from ca. 16.1/ha in seasonally flooded marsh, to 42.5/ha in savanna with secondary growth near villages (Misonne 1963). Densities decreased in savanna habitats away from villages (ca. 23.3/ha) (Misonne 1963).

Adaptations Presumably similar to *Otomys irroratus*.

Foraging and Food Herbivorous, feeding on a range of green grass, reed and herb stems, shoots, bark and occasionally roots, seeds and berries (Kingdon 1974). Verheyen & Verschuren (1966) noted fragments of ants in stomach contents. They may damage forest plantations; in DR Congo, 65% of trees in one plantation had been damaged, with trees of 3–15 mm diameter being completely ring-barked.

Social and Reproductive Behaviour Activity mostly crepuscular. Timid and sensitive to noise in captivity. Few vocalizations, but squeaks and a loud screech have been noted (Kingdon 1974).

Reproduction and Population Structure Litter-size 1 or 2, always <4. Births recorded throughout year; up to five litters per year. Capable of breeding before three months of age. Adult behaviour is attained within two weeks. Mean birth-weight 12.5 g; young grow at a rate of 10 g per week (Kingdon 1974).

Predators, Parasites and Diseases Major predators in East Africa include the African Grass-owl *Tyto capensis* and Augur Buzzard *Buteo rofufuscus*. They have been implicated as a plague reservoir (F. Dieterlen in Kingdon 1974), but as contact with humans is limited, their role as an immediate transmitter of the disease must be slight.

Conservation IUCN Category: Least Concern.

Otomys typus ETHIOPIAN VLEI RAT

Fr. Rat du vlei d'Éthiopie; Ger. Äthiopische Lamellenzahnratte

Otomys typus (Heuglin, 1877). Reise in Nordost-Afrika 2: 77. Simien Mts, Ethiopia.

Taxonomy Originally described in the genus *Oeromys*. The taxonomy of *O. typus* is uncertain. In Ethiopia, there are two genetically distinct *Otomys*, 'Sp. A' and 'Sp. B', both currently included in *O. typus* (Lavrenchenko *et al.* 1997); subsequently formally named as *O. yaldeni* sp. nov. and *O. helleri*, respectively (Taylor *et al.* 2011). Because there are variations in the number of laminae on M³, size, skull shape and pelage, Musser & Carleton (2005) recognize *jacksoni* (with seven laminae), *dartmouthi* (six laminae) and *uzungwensis* (seven laminae) as distinct species, thus restricting the range of *O. typus sensu stricto* (eight or nine laminae) to the Ethiopian Highlands. However, similar variation has been observed even within Ethiopian populations (six to nine laminae, large size and shape variation), and a recent molecular, morphological and cytogenetic synthesis (Taylor *et al.* 2011) restricts *typus s.s.* to certain mountains west of the Great Rift Valley in Ethiopia (Simien and Guna Mountains in the north, extending to the highlands of the western rim of the Rift Valley) and recognizes a further 11 valid taxa: *cheesmani* sp. nov. (Ethiopia), *dartmouthi* Thomas, 1906 (Rwenzori Mts), *fortior* Thomas, 1906a (south-western Ethiopia), *helleri* Frick, 1914 (Bale Mts, Ethiopia), *jacksoni* Thomas, 1891 (Mt Elgon), *orestes* Thomas, 1900 (Mt Kenya and Abderdare Mts), *simiensis* sp. nov. (Simien

Mts, Ethiopia), *thomasi* Osgood, 1910 (central Kenya), *uzungwensis* Lawrence and Loveridge, 1953 (Eastern Arc Mts to Nyika Plateau), *yaldeni* sp. nov. (Bale Mts, Ethiopia), *zinki* Bohmann, 1943 (Mt Kilimanjaro). Synonyms: *degeni*, *malkensis*, *percivali*. Subspecies: none. Chromosome number: 2n = 52 (Mt Elgon; A. Kumirai & P. J. Taylor unpubl.), 2n = 56 (Sp. A; Ethiopia) and 2n = 57–58 (Sp. B; Ethiopia).

Description Medium-sized, smooth-coated rat. Dorsal pelage speckled bright tawny-brown. Ventral pelage grey. Colours of dorsal and ventral pelage merge along the flanks. Ears grey, short, prominent and rounded. Feet dark grey to black. Tail short (ca. 46% of HB). Each upper incisor with single groove; each lower incisor with two deep grooves. M³ with typically seven or eight laminae; however, 'Sp. A' is believed to have six laminae and 'Sp. B' has seven or eight laminae. M₁ with four laminae. Males tend to be larger than ♀♀. Nasal bones expanded. Petrotympanic foramen round. Nipples: presumably 0 + 2 = 4.

Geographic Variation None recorded.

Similar Species In Ethiopia, only one species is currently

recognized. Elsewhere in East Africa other *Otomys* spp. have fewer laminae on M³.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Widespread in moist localities at higher altitudes in Ethiopia, and discontinuously southwards to Zambia. Recorded from Ethiopia (many localities, as *O. typus*, *cheesmani*, *fortior*, *helleri*, *simiensis*, *yaldeni*), Mt Elgon (Uganda/Kenya, as *jacksoni*), Aberdare Ranges (as *orestes*), Kilimanjaro (as *zinki*), Mau Plateau (as *thomasi*) and Rwenzori Mts (Uganda/DR Congo, as *dartmouthi*). Also recorded from Uzungwa Mts (WCTanzania), Nyika Plateau (Malawi) and Nyika Plateau (NE Zambia) as *uzungwensis*. Altitudinal range on Rwenzori Mts 3300–3900 m.

Habitat Occurs only in moist grasslands and swamps from 1300 to 4300 m. Prefers habitat with dense grass cover, and avoids wet marshlands (Clausnitzer 2003). In afroalpine habitats on Mt Elgon, this species is broadly syntopic with *O. barbouri*; however, *O. typus* prefers drier grasslands and *O. barbouri* prefers wetter habitats.

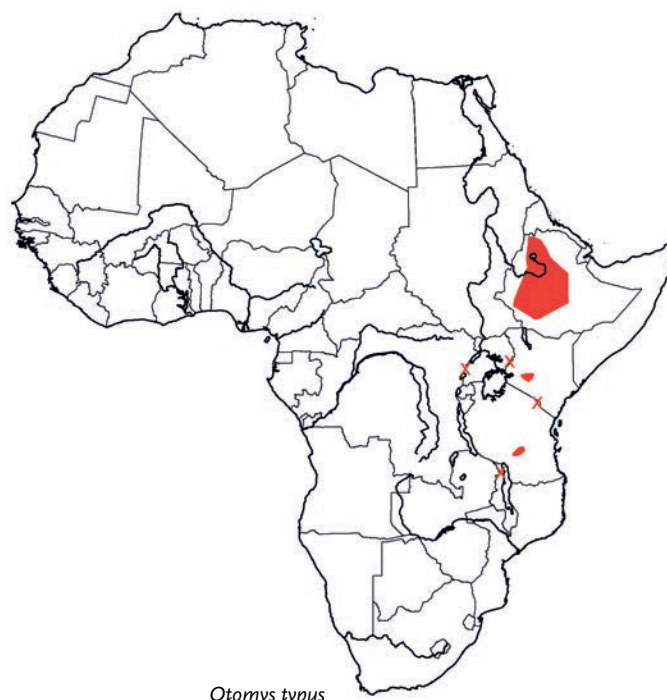

Abundance May be abundant in suitable habitats, but abundance often underestimated because of acute trap-shyness (Sillero-Zubiri *et al.* 1995a, Clausnitzer 2003). Comprised 6% of rodents in grasslands of Simien Mts, Ethiopia (Müller 1977). On Mt Elgon (Kenya/Uganda), population numbers rather stable throughout year; density is ca. 15/ha to 30/ha, and mean biomass is 937–1941 g/ha depending on the vegetation (Clausnitzer 2003).

Adaptations Terrestrial. Active throughout 24 hours in the Bale Mts, Ethiopia; about 75% of captures in morning and 25% at night (Sillero-Zubiri *et al.* 1995a). In the Simien Mts, Ethiopia, as likely to be trapped during daytime as at night (Müller 1977). Animals are nervous during daylight and tend to stay under cover.

Foraging and Food Herbivorous, specializing on grass stems and leaves. Well-used runways radiate from good cover to feeding sites. On Mt Elgon, major food items were *Festuca pilgeri* (ca. 50%) and other grasses (*Kolera capensis*, *Argosies gracilifolia*) (ca. 50%). Flowers of the shrubby composite *Helichrysum*, when available, were the only other significant item of food (Clausnitzer 2003).

Social and Reproductive Behaviour Aggressive, but not territorial. Median home-range on Mt Elgon varies according to sex and habitat: 401–728 m² for ♂♂ (n = 45) and 181–481 m² for ♀♀ (n = 45) (Clausnitzer 2003). Home-ranges of individuals have considerable overlap.

Reproduction and Population Structure Limited samples from Simien Mts, Ethiopia, where rainfall is seasonal, suggest seasonal breeding during the wet season (May–Dec) (Müller 1977). On Mt Elgon, where seasonal changes in climate are slight, reproductively active adults (scrotal ♂♂, pregnant and parous ♀♀) and juveniles were trapped throughout the year (Clausnitzer 2003). Litter-size: 1.1 (1–2), n = 9. Young precocial; nipple-cling to mother. No evidence that ♀♀ use nests (Clausnitzer 2000, 2003). Sex ratio of captures close to unity. On Mt Elgon, population numbers rather stable throughout year; juveniles form about 20% of population throughout the year (Clausnitzer 2003).

Otomys typus

Predators, Parasites and Diseases In Bale Mts, Ethiopia, form a significant prey of Ethiopian Wolves *Canis simensis* (17% of prey numbers and 8% of prey biomass), greater than would be expected from trapping (Sillero-Zubiri *et al.* 1995b). On Mt Elgon, Servals *Leptailurus serval* are a major predator: teeth of *Otomys* (*O. typus* and *O. barbouri*) comprised 95% of all teeth present in 100 faecal samples (Clausnitzer 2003). Probably also prey for owls and diurnal raptors.

Conservation IUCN Category: Least Concern.

Although abundant in suitable localities, geographic ranges are small and populations are disjunct. Populations in swamps and wetlands may be threatened by conversion of wetlands into agricultural land.

Otomys unisulcatus KAROO VLEI RAT (BUSH KAROO RAT)

Fr. Rat du vlei de Karoo; Ger. Karoo-Lamellenzahnratte

Otomys unisulcatus F. Cuvier, 1829. Hist. Nat. Mammifères, Pt. 60. South Africa. (Type locality nominated as Matjiesfontein, Western Cape Province, South Africa; Roberts 1951.)

Taxonomy Referred to as *Myotomys unisulcatus* by Musser & Carleton (2005). This species and *O. sloggetti* show close affinities to *Parotomys* spp. Synonyms: *abaniensis*, *bergensis*, *broomi*, *granti*. Subspecies: none. Chromosome number: $2n = 28$ (Robinson & Elder 1987).

Description Large to medium-sized rat with distinct black line on upper surface of tail. Pelage long, dense and shaggy. Dorsal pelage buffy-brown to dark chocolate-brown; hairs grey at base, buffy-yellow at tip. Long pure black hairs interspersed throughout pelage, especially on head and back (but not on flanks). Ventral pelage buffy-white; hairs grey at base, buffy-yellow at tip. Head blunt, similar in colour to back. Eyes without eye-ring. Ears darkly pigmented, large and rounded, well covered with hair, partly obscured by hair on cheeks. Fore- and hindfeet buffy-white. Tail short (ca. 60% of HB), covered with short bristles, black above, dull white or black below. Each upper incisor with single shallow groove towards outer edge; each lower incisor ungrooved (occasionally with faint shallow groove). M^3 with four laminae and a small circular posterior section. M_1 with three laminae (and one partial anterior lamina). Nasal bones barely expanded. Petrotympanic foramen round. ♂♂ on average larger than ♀♀ for most measurements. Nipples: $0 + 2 = 4$.

Geographic Variation None recorded.

Similar Species Four species of *Otomys* are potentially sympatric, but not necessarily syntopic:

Otomys irroratus. Slightly larger mean HB; M^3 with 6(7) laminae; M_1 with four laminae; two grooves on each lower incisor tooth; does not build stick nests; does not whistle.

Otomys saundersi. Smaller mean HB; M^3 with 6(5) laminae; M_1 with four laminae; two grooves on each lower incisor tooth; does not build stick nests; does not whistle.

Parotomys brantsi. Smaller mean HB; M^3 with two laminae; M_1 with four laminae; two grooves on each upper incisor tooth; constructs large complex underground burrow systems; whistles when alarmed.

Parotomys littledalei. Slightly smaller mean HB; M^3 with three laminae; M_1 with three laminae; no grooves on upper incisor teeth; constructs large complex above-ground burrow systems; whistles when alarmed.

Distribution Endemic to Africa. South-West Cape and South-West Arid (Karoo) BZs. Largely confined to the Nama- and Succulent-Karoo regions within the Northern Cape, Eastern and Western Cape Provinces, South Africa, and not found north of the Orange R. Also extends southwards marginally into fynbos. Distribution may be limited by veld fires, which can easily destroy their stick lodges (see below), especially in areas such as the Kalahari that are prone to lightning strikes (Kerley & Erasmus 1992b).

Otomys unisulcatus

Habitat Shrub- and Karoo-like vegetation, including rocky outcrops or rocky areas. Often associated with the beds and banks of dry water-courses (Dieckmann 1979). In Eastern Cape Province, South Africa, associated with areas of cover provided by various *Lycium* bushes (Brown & Willan 1991). On the west coast of South Africa, often associated with coastal dunes predominantly in lower-lying sandy areas protected from the prevailing SW wind (Vermeulen & Nel 1988). Tends to shun damp situations and dense riverine habitats.

Abundance Common in suitable habitats throughout its range. Maximum recorded density of 64/ha in Eastern Cape Province, South Africa (Brown 1987). In Western Cape Province, a density of 155 lodges/ha (Vermeulen & Nel 1988) suggests that much higher population densities are possible. The presence of these rats is conspicuous due to the presence of their nesting lodges, characterized by a build-up of accumulated sticks (see below).

Adaptations Diurnal and terrestrial. In Eastern Cape Province, South Africa, activity peaks during the cooler hours in summer (06:00–10:00h, 16:00–18:00h) but during the warmer hours (10:00–15:00h) in the winter (Brown & Willan 1991). In Western Cape Province, South Africa, Karoo Rats are crepuscular (Vermeulen & Nel 1988); nocturnal activity has not been recorded. Activity periods outside the nest last from less than five minutes to more than an hour, amounting to approximately three hours per day (Brown & Willan 1991).

Bush Karoo Rats construct elaborate, dome-shaped lodges made of intricately interwoven sticks and twigs (Vermeulen & Nel 1988). Lodges are constructed at the base of shrubs or shrubby trees (Brown & Willan 1991), mostly on level ground (88%, $n = 43$; Vermeulen & Nel 1988). Active lodges have a series of 1–5 runways radiating out from them, mostly less than 5 m long (Brown 1987). These runways may interconnect lodges, or run to trees and bushes without any lodges beneath them. Maximum recorded size of sticks used to build a lodge is 20×300 mm, though typically sticks are less than 10×100 mm (diameter \times length) (Brown 1987). Lodges may be up to 0.45 m high and 1.3 m in diameter (Brown 1987, Du Plessis & Kerley 1991). Each lodge has a number of entrances (6–11), which open at or above ground level. Internally, lodges are criss-crossed by passages and tunnels leading to nests, latrines and entrances. Beneath the lodge, one or two tunnels extending to 30 cm below the ground surface may be present; these provide protection from predators and buffer ambient weather conditions (Vermeulen & Nel 1988, Brown & Willan 1991). Some smaller lodges have no underlying tunnels, whilst some tunnels underneath the canopy of a shrub are not covered with sticks. Each lodge has 1–2 nest chambers, incorporated at the base of tunnels and lined with shredded wood. Bush Karoo Rats have also been recorded sheltering under rocky outcrops and log piles, as well as gaps in stone walls (Brown 1987). In Eastern Cape Province, they use as many as 20% of suitable shrubs for nesting (Brown 1987). While these provide protection from both predators and climatic extremes, they do not afford the same thermal buffering as provided by tunnels (Du Plessis *et al.* 1992, Jackson *et al.* 2002). Brown & Willan (1991) suggest the inclusion of tunnel systems beneath lodges in Eastern Cape Province, but not in Western Cape Province, may relate to the colder conditions where extreme minimums reach ca. -7.5°C , compared to 0.7°C .

The thermal physiology of Bush Karoo Rats appears to be better suited to the microclimate of their surface lodges than to the macroclimate of the arid and semi-arid environment. Thus, individuals exhibit relatively low thermal conductance and show considerable signs of heat stress at 37°C (Du Plessis *et al.* 1989, Jackson *et al.* 2004). The kidneys are only moderately adapted to xeric conditions (Pillay *et al.* 1994, Jackson *et al.* 2004); and urine osmolality, and possibly hindgut water retention, are more similar to that of otomyine rodents from mesic habitats than many other arid-living rodents (Jackson & Spinks 1998, Jackson *et al.* 2004).

Foraging and Food Strictly herbivorous, feeding on the leaves and fruits of a wide range of plant species (Brown 1987, Du Plessis *et al.* 1991). Foraging pathways radiate outwards from lodges to food plants; here, individuals collect food and refuge-building materials, but generally do not travel more than ca. 5 m from their lodges. Herbaceous vegetation is typically eaten *in situ*, whereas cropped material is carried back to the protection of a shrub or lodge. Individuals may forage alone, or sometimes in groups of up to eight individuals (Brown & Willan 1991). When more than one animal is foraging in the open, individuals tend to move greater distances from the protective bush (Brown 1987). They may also feed within the shelter of bushes, which they climb readily, typically to a height of <1 m, although they occasionally climb as

high as 3 m to feed. Bushes where the rats have been feeding are noticeable because of circular ‘windows’ of vegetation (diameter ca. 15 cm) that have been removed by foraging rats. Bush Karoo Rats forage mainly on the trees and bushes within which their lodges are built and nearby herbaceous vegetation. Occasionally Bush Karoo Rats forage up to 50 m from their home lodge (Brown & Willan 1991).

Stomach analysis shows that both plant stems (30%) and leaves (70%) are included in the diet, but not insects (Vermeulen & Nel 1988). Generally, plant species are consumed in proportion to availability; 60 species of food plants have been recorded in the southern Karoo (Du Plessis *et al.* 1991). Shrubs rather than annuals or trees dominate the diet (Du Plessis *et al.* 1991). In the Eastern Cape Province, Karoo Rats feed on *Acacia karroo*, *Atriplex* sp., *Lycium austrinum*, *L. horridum*, *Mesembryanthem* sp. and *Tribulus* sp. Both the leaves and highly hydrated fruits of *Lycium* bushes are heavily utilized (Brown & Willan 1991). In the southern Karoo, *Lycium* bushes, *Galenia africana*, *Drosanthemum* sp. and *Psilocaulon* sp. predominate in the diet (Du Plessis *et al.* 1991), while in the coastal region of the Western Cape Province, *Ruschia* sp., *Exomis microphylla* and *Zygophyllum flexuosum* are important in the diet (Vermeulen & Nel 1988). The nature of the herbivorous diet is of key importance to survival within semi-arid areas.

Social and Reproductive Behaviour Several individuals may share a lodge, up to a maximum of eight individuals (Brown 1987). The exact nature of the relationship between individuals is not understood, though they probably represent an extended family group. Individuals move frequently between a limited number of lodges. The most common social group is an adult pair, though various combinations including up to four adult $\delta \delta$, three adult ♀ , as well as subadults and juveniles have been recorded. Laboratory studies show that most interactions between lodge mates appear to be amicable, with a degree of ritualized aggression between $\delta \delta$. However, interactions between residents of different lodges are characterized by high levels of direct aggression, particularly by $\delta \delta$, in which individuals may receive fatal wounds during fights (Brown 1987).

Reproduction and Population Structure Reproductive activity varies geographically. In areas receiving mixed summer and winter rainfall, the highest percentage of reproductively active animals occurs during the summer months (83.3% in Nov) and drops to 50.0% during Jul (Brown 1987). In Eastern Cape Province (average annual rainfall 396 mm, with rain in both summer and winter), breeding occurs throughout the year, although at a reduced rate in winter (Brown 1987). In Namaqualand, South Africa, young have been observed in Aug–Sep, following winter rainfall, whilst individuals trapped in Jan showed no signs of pregnancy or lactation (T. Jackson pers. obs.). Along the coast of Western Cape Province, which also receives predominantly winter rainfall, a pregnant ♀ was trapped in May, while young were heard or seen in Jun and Jul. Together, these data suggest breeding is opportunistic and occurs in relation to local rainfall patterns.

Gestation: 37 days. Litter-size (in captivity): 2.09 (1–3); reproductive effort: 0.58. At birth young are semi-precocial; dorsal and lateral pelage well developed, ventral pelage absent; upper and

lower incisors erupted; weight 6.1–9.6 g. Ability to smell, and ears open, on Day 4. Eyes fully open Day 6. Young nipple-cling until ca. Day 6. Age of first reproduction: 6 weeks (♂♂), 5 weeks (♀♀). Inter-litter interval of 40 days suggests ♀♀ exhibit a postpartum oestrus (Pillay *et al.* 1993, Pillay 2001).

Predators, Parasites and Diseases Preyed upon by small carnivores, snakes and raptors. Within the Little Karoo of Western Cape Province, Bush Karoo Rats are the commonest prey of the Pale Chanting Goshawk *Melierax canorus*. They are also preyed upon by Jackal Buzzards *Buteo rufofuscus* in northern Namaqualand. Nests of bush rats have been destroyed by Black-backed Jackals *Canis mesomelas*. Potential predators are the Small Grey Mongoose *Galerella pulverulenta*, Water Mongoose *Atilax paludinosus*, Yellow Mongoose *Cynictis penicillata*, Small Spotted Genet *Genetta genetta*, Cape Fox *Vulpes chama*, Bat-eared Fox *Otocyon megalotis*, Mole Snake *Pseudaspis cana*, Sweep-slang *Psamophis notostictus*, Cape Cobra *Naja nivea*, Boomslang *Dispholidus typus* and Black Eagle *Aquila verreauxi* (Vermeulen & Nel 1988). Other predators may include African Wild Cat (*Felis lybica*). Ectoparasites include 26 spp. of fleas and eight species of ticks (De Graaff 1981, and references therein), as well as sucking lice (Vermeulen & Nel 1988). The ticks are of veterinary significance, and may carry babesias, rickettsias and theileriosis. Bush Karoo Rats are important vectors of plague (De Graaff 1981). Three of eight individuals dissected harboured 1–3 tapeworms (Vermeulen & Nel 1988).

Conservation IUCN Category: Least Concern.

Measurements

Otomys unisulcatus

HB (♂♂): 158 (128–190) mm, n = 18

HB (♀♀): 147 (110–205) mm, n = 22

T (♂♂): 94 (78–106) mm, n = 18

T (♀♀): 90 (63–105) mm, n = 22

HF (♂♂): 29 (27–32) mm, n = 18

HF (♀♀): 28 (22–30) mm, n = 22

E (♂♂): 24 (21–27) mm, n = 18

E (♀♀): 23 (20–33) mm, n = 22

WT (♂♂): 105 (61–156) g, n = 18

WT (♀♀): 87 (67–122) g, n = 22

GLS (♂♂): 35.7 (31.9–39.4) mm, n = 18

GLS (♀♀): 34.7 (32.5–37.5) mm, n = 22

GWS (♂♂): 18.5 (15.2–20.9) mm, n = 18

GWS (♀♀): 17.4 (15.8–19.1) mm, n = 22

M¹–M³ (♂♂): 6.9 (5.9–7.7) mm, n = 18

M¹–M³ (♀♀): 7.0 (5.9–7.9) mm, n = 22

Northern and Western Cape Provinces, South Africa (TM)

GENUS *Parotomys*

Whistling Rats

Parotomys Thomas, 1918. Ann. Mag. Nat. Hist., ser. 9, 2: 205. Type species: *Euryotis brantsii* A. Smith, 1834.

Parotomys brantsii.

The genus *Parotomys* contains two species, *Parotomys brantsii* and *P. littledalei*. Both species are endemic to the South-West Arid BZ of southern Africa and are the most arid-occurring of all otomyine rodents. They are restricted to sandy habitats suitable for the construction of their complex burrow systems. Both are herbivorous and diurnally active above ground.

Parotomys is similar in many respects to *Otomys*, but is distinguished from *Otomys* principally by the enlarged auditory meatus, which has a strongly projecting thickened process on its anterior edge, a narrow basioccipital, lower incisors that lack grooves or are only faintly grooved, and inflated auditory bullae (De Graaff 1981) (Figure 94). The molar teeth are laminate, but are much less laminate than in *Otomys*, and M³ has only two or three laminae (cf. 4–10 in *Otomys*). The upper incisors of *P. brantsii* have a deep outer and shallow inner groove, those of *P. littledalei* are without grooves. Nasal bones are barely expanded (Figure 92). *Parotomys* is noteworthy amongst the Otomyinae in producing high-pitched, single note, whistle-like calls, that may be repeated in non-rhythmic bouts.

The current generic distinction of the genus *Parotomys* from *Otomys* is questionable and is principally based on one morphological character – the size of the auditory bullae (Misonne 1974, Meester *et al.* 1986). Significantly, Pocock (1976) suggested that the dental characters of *O. sloggetti* and *O. unisulcatus* are more similar to *Parotomys* than to other *Otomys* species, while the diameter of their bullae and nasal width are intermediate between the more mesic *Otomys* species and the arid-occurring *Parotomys*. The original morphological characters for separation of the genera are not supported by more recent biochemical and cytogenetic analyses. These studies – protein electrophoresis (Taylor *et al.*

Figure 94. Skull and mandible of *Parotomys littledalei* (BMNH 23.5.9.89).

1989), immuno-electrotransfer analysis (Contrafatto *et al.* 1994), immunoblot analysis (G. Contrafatto in litt.) and mitochondrial DNA (Maree 2002) – variously suggest a closer phylogenetic relationship between the species of *Parotomys* and *O. sloggetti* or *O. unisulcatus* than between the two *Parotomys* species. Furthermore, Rambau *et al.* (1997) concluded that a high degree of chromosomal homology exists between *P. brantsii* and *O. unisulcatus*, but not between *O. unisulcatus* and *O. irroratus*, which they relate to habitat

fragmentation processes for *O. irroratus*. *Liutomys*, named as a subgenus by Thomas (1918) and used by Roberts (1951) as a genus, is now regarded as a synonym (Musser & Carleton 1993, 2005).

These relationships are, in part, supported by differences in sperm and kidney morphology. Sperm morphologies are similar for *P. brantsii* and *O. sloggetti*, and differ from those of mesic species. *Otomys unisulcatus* differs from any other species by having very small mitochondria in the mid-piece (Bernard *et al.* 1991). Indeed, several studies suggest that the southern African otomyine rodents may best be divided into an arid group and a mesic group (Pocock 1976, Taylor *et al.* 1989, Contrafatto *et al.* 1994). This is confirmed by Pillay *et al.* (1994), who found a dichotomy between arid species and mesic species with respect to kidney morphology, primarily with respect to relative cortex and medulla proportions. However, while the *Parotomys* species and *O. unisulcatus* could be included in an arid group, *O. sloggetti* grouped with the mesic otomyines.

Present evidence suggests that *Prototomys campbelli*, which occurred ca. 3.6 mya, was ancestral to all modern Otomyinae (Pocock 1976). Biochemical, palaeontological and morphological data support the existence of two evolutionary lineages of otomyines in southern Africa that were presumably derived from this extinct fossil species, one essentially arid-adapted and the other mesic-adapted. The arid-adapted group includes the two *Parotomys* species, as well as *O. unisulcatus* and *O. sloggetti*. These data do not, however, support a generic distinction between *Otomys* and *Parotomys*, suggesting either that the arid *Otomys* species be included in *Parotomys* or *Parotomys* should be considered a synonym of *Otomys* (Meester *et al.* 1992).

The two species are distinguished on the characteristics of their whistle-like calls, their enlarged auditory meatus and on the form of the incisor teeth.

Tim P. Jackson

Parotomys brantsii BRANTS'S WHISTLING RAT

Fr. Rat de Brant; Ger. Brants Pfeifratte

Parotomys brantsii (A. Smith, 1834). S. Afr. Quart. J. 2: 150. Little Namaqualand, Cape Province, South Africa; 'towards the mouth of the Orange River'. (Type locality fixed as Port Nolloth, Northern Cape Province, South Africa [Thomas & Schwann 1904].)

Taxonomy Originally described as *Euryotis brantsii*. Synonyms: *brantsi*, *deserti*, *luteolus*, *pallida*, *rufifrons*. Subspecies: none. Chromosome number: $2n = 42$ (Meester 1988).

Description Medium- to large-sized rat, very similar to *P. littledalei*, with blunt head and reddish-brown tail. Pelage soft and dense (hairs ca. 6–7 mm). Dorsal pelage sienna-yellow speckled with blackish-brown; hairs dark grey at base, yellowish at tip; long pure black hairs, especially on mid-dorsal line. Flanks slightly paler. Ventral pelage greyish-white; hairs grey at base, off-white or pale yellow at tip. Head greyish-white, with blunt muzzle; nasal region and forehead russet. Ears large and rounded, darkly pigmented, with short brown or pale hairs. Limbs short; forefeet

with four long digits and long slender claws (Digit 1 reduced, hardly visible); hindfeet with five well-developed digits and long slender claws. Tail short (ca. 63% of HB), covered with hair; dark brown above, reddish-orange on sides and below. Each upper incisor one deep outer groove and one shallow inner groove; lower incisors without grooves. M^3 small (cf. *Otomys*) with two laminae. Nasal bones barely expanded. ♂♂ on average larger than ♀♀ for most measurements. Vocalizes using a single, high-pitched, alarm whistle (see below). Nipples: $0 + 2 = 4$.

Geographic Variation Mean HB length and weight of individuals in South Africa are greater than those in Namibia, and ♂♂ are also larger than ♀♀ (e.g. in South Africa: ♂♂ HB: 215 [177–249] mm,

*Parotomys brantsii*

T: 87 [70–154] mm, WT: 138 [84–206] g; ♀♀ HB: 202 [161–236] mm, T: 82 [58–97], WT: 121 [80–214] g [T. Jackson unpubl.] (see also Measurements).

Similar Species

P. littledalei. Similar HB; on average lighter weight; more pointed ears and nose; M³ with three laminae; upper incisors without grooves. Alarm whistle shorter and lower pitched.

Distribution Endemic to Africa. South-West Arid BZ (Karoo and southern parts of the Kalahari Desert). Recorded from Western and Northern Cape Provinces of South Africa, S Namibia and SW Botswana. Distribution mostly in areas with mean annual rainfall <300 mm (Smithers 1983).

Habitat Hard sandy soils throughout the Nama and Succulent Karoo, as well as the southern Kalahari. In the Kalahari Gemsbok N. P., South Africa and Botswana, distribution is largely correlated with the presence of the shrub *Rhigozum trichotomum* on dune slopes and banks of dry river beds (Nel & Rautenbach 1974).

Abundance Populations undergo large-scale fluctuations in numbers in response to environmental conditions. During favourable periods, densities exceed 50 animals/ha, with populations increasing as much as four-fold through the course of a breeding season (T. Jackson unpubl.).

Adaptations Diurnal and terrestrial; occasionally scansorial. Feeding and foraging activity is mostly during the early morning and late afternoon (Nel & Rautenbach 1974, Jackson 1998a). Probably polyphasic, with most nocturnal activity restricted to underground movements. However, also recorded foraging on moonlit nights in the southern Kalahari. In Namaqualand, remains above ground all day during winter, mainly resting through the middle of the day,

though retiring underground during the hottest period of the day in summer (Jackson 1998a).

Brants's Whistling Rats construct large and complex burrows (De Graaff & Nel 1965, Du Plessis & Kerley 1991). Many burrows are constructed in relatively open localities (cf. *P. littledalei*), as well as under bushes (e.g. *Rhigozum trichotomum*, *Lycium* sp. and *Zygophyllum retrofractum*). Burrows often associated with raised mima-like mounds (*heuweltjies*). In Namaqualand, some burrows contain 1–6 nest chambers, and are accessed by more than 500 entrances (mean 92) and cover an average area of 72.9 m². Individuals switch nest chambers, on average, every 1.6 nights (Roper *et al.* 2002). Such behaviour may reduce the rate at which ectoparasites, especially fleas, accumulate (Roper *et al.* 2002). Many tunnels bifurcate shortly before they reach the surface of a burrow, thus increasing the number of entrances. The numerous entrances provide many quick 'escape holes' into the burrows – a useful feature for a diurnal rodent living in an open habitat (Jackson 2000a). The burrows are well buffered from variations in ambient temperature, and have a narrow average diel temperature range (<4 °C) compared with the temperature at the surface (>14 °C). Maximum burrow temperatures are independent of maximum ambient shade temperature (Jackson *et al.* 2002).

Rather surprisingly, in view of the aridity of their habitat, Brants's Whistling Rats do not show any unusual physiological adaptations to reduce water loss (Jackson *et al.* 2004). They are strictly herbivorous and the water content of the food is probably of greater importance to survival than in many other arid-occurring rodents. They exhibit hyperthermia at 37 °C, and are the most tolerant of the southern African Otomyinae to such high ambient temperatures. Unlike many desert rodents, they do not exhibit a lower resting metabolic rate (recorded as 1.15 ml O₂/g/h) than expected for body size, while their lower critical temperature (23 °C) is comparatively low and the thermal neutral zone of 23–37 °C is broad (Jackson *et al.* 2004).

Alarm calls, used to signal predators, have a dominant frequency of 10.0 kHz and mean call duration of 164 ms – longer and higher pitched than those of *P. littledalei* (Le Roux *et al.* 2002). These whistling rats do not differentiate predator types by means of vocalizations; rather their calls are 'urgency-based' and indicate perceived threat levels. Thus, high-risk encounters such as those evoked by a fast-flying raptor provoke a short-duration call before the rat bolts underground, whereas low-risk encounters such as those provoked by a slow-moving snake elicit a relatively long-duration call while the caller remains above ground and continues to observe the threat (Le Roux *et al.* 2002).

Foraging and Food Exclusively herbivorous. Feeds on a wide range of plants (Du Plessis *et al.* 1991, Jackson 1998b), including woody shrubs, annuals, geophytes, grasses and various succulents, but not seeds or other dry plant material. In suitable habitats, whistling rats restrict much of their foraging to the confines of their extensive burrows and individuals are seldom more than 30 cm from an entrance. Typically pieces of vegetation are nipped off and eaten, whilst some individuals occasionally climb into shrubs to feed. Whistling rats may be described as 'central-place foragers', carrying larger food items greater distances than small ones (Jackson 2001). During the hot dry summer, individuals have also been observed digging for bulbs. Fresh plant material may be eaten immediately, particularly in the early morning and late afternoon when animals are most active.

Larger items of fresh material are typically stored underground (less often stored above ground at a burrow entrance), usually near a nest chamber, rather than being eaten immediately. Much of this stored material is collected in the late afternoon, and is believed to act as an overnight food source (Jackson 2001). In some areas, such as N Namaqualand, foraging is largely confined to above-ground areas within the boundaries of a burrow. However, individuals will also move between adjacent burrows, located a mean distance of 5.1 m apart in Namaqualand, in search of food. Burrows are inter-connected by a series of well-used pathways. When visiting neighbouring burrows, individuals do so largely to feed and not to collect material for later consumption (Jackson 2001).

The burrowing and foraging behaviour plays a key ecological role. In natural ecosystems, when population numbers are high, whistling rats are capable of causing heavy disturbance to plant communities with a concurrent reduction in plant species richness and abundance (T. Jackson unpubl.). Soils associated with their burrows have higher mineral concentrations: sodium may be 8.7 times more concentrated than in the surrounding soils, and magnesium may be 1.5 times more concentrated. This is paralleled by an increase in soil alkalinity. However, at lower population densities, they play an important role in rehabilitating mined areas, by creating soil patches around their burrows with higher pH, reduced conductivity and increased microbial activity, which are conducive to plant growth (Desmet & Cowling 1999).

Social and Reproductive Behaviour Typically, individuals occupy separate burrows and may be considered solitary. Burrows are, however, normally situated in close proximity to one another (e.g. range of distances between burrows is 1–25 m in Namaqualand), such that interactions can be frequent between individuals. At high population densities, a maximum of four individuals may share a burrow. Even so, rats will maintain discreet territories in a burrow. The breeding system is based on scramble competition polygyny (Jackson 1999); ♂♂ solicit ♀♀ during the breeding period searching actively for mates in burrows near to their own. Males are, therefore, seen away from their burrows on more occasions than are ♀♀. However, while the maximum distances that ♂♂ are observed away from their burrows (mean = 33 m) is greater than for ♀♀ (mean = 20 m), average movement distances from the centre of their ranges (males = 9 m, females = 6 m) do not differ between the sexes (T. Jackson, P. Fleming & N. Bennett, unpubl.). Aggressive behaviour is mostly directed by ♀♀ towards intruding ♂♂, and male–male aggression is limited. Natal dispersal distances are short and do not differ with gender, averaging 38 m for ♀♀ and 40 m for ♂♂. More than 50% of adults disperse less than 20 m from their natal burrows (T. Jackson, P. Fleming & N. Bennett unpubl.) and many individuals, both ♂ and ♀, may be considered philopatric.

Reproduction and Population Structure Reproduction is opportunistic, and dependent on rainfall. In areas of summer rainfall, including the southern Kalahari, the pregnancy rate is greatest during the summer months. In winter rainfall areas, such as Namaqualand, the greatest number of reproductively active (pregnant or lactating) ♀♀ is during winter–spring (May–Oct), though lactating ♀♀ have also been captured in Jan (Jackson 2000b). Gestation: ca. 38 days. Embryo number: 2.1 (1–3, n = 9; SW Botswana; Smithers 1971).

Litter-size: 3.4 (3–4, n = 14; Namaqualand; Jackson 2000b). No information available on birth-weight or ontogeny. Young forage above ground from Day 7. Growth rate: 1.2 g/day until independence from mother at 6–7 weeks of age and 55% of adult weight (Jackson 2000b). Young have the ability to make overnight food stores, collect nest material and defend a burrow against conspecifics by Day 35. Sexual maturity: Day 35 (♀♀), unknown (♂♂). Young disperse from their natal nest area at the time when ♀♀ potentially reach sexual maturity. Females have a postpartum oestrus, and may produce at least four litters during the annual breeding period. Females typically survive to breed for 1–2 years.

The behaviour of ♀♀ is modified as a result of the birth of their young. After parturition, they spend extended periods (>50% during daytime) underground, interspersed with bouts of food collection (Jackson 2000b). At this time, feeding activity above ground is reduced compared to that during pregnancy and after the emergence of young, although the times of day when foraging occurs remain unchanged. Females carry 43% of food material underground after the birth of the young and prior to their emergence, compared to only 10% during pregnancy. By the time young are 12–14 days of age, ♀♀ spend at least 75% of time above ground again. Female anti-predator vigilance increases from 5.5% of activity when young are underground to 14.1% when they emerge above ground. After the birth of young (Day 1), mothers nipple-drag their young for about 12% of the time when they are above ground; this increases to 35% until Day 8–9, and declines thereafter. Nipple-clinging by young no longer observed from Day 14 (Jackson 2000b). In some regions, a disproportionately greater die-off of ♂♂ has been recorded during the breeding period, with almost all ♂♂ disappearing from the population (T. Jackson unpubl.).

Predators, Parasites and Diseases Common raptor predators include Pale Chanting Goshawks *Melierax canorus*, Jackal Buzzards *Buteo rufofuscus*, Lanner Falcons *Falco biarmicus* and Booted Eagles *Hieraaetus pennatus*, as well as Barn Owls *Tyto alba* and Spotted Eagle-owls *Bubo africanus* at dusk. Small mammalian predators include Yellow Mongooses *Cynicits penicillata*, Ratels *Mellivora capensis*, Black-backed Jackals *Canis mesomelas* and African Wild Cats *Felis lybica*. Snake predators include Puff Adders *Bitis arietans*, Black Spitting Cobras *Naja nigricollis*, Mole Snakes *Pseudaspis cana* and Cape Cobras *Naja nivea*. Whistling rats have also been recorded in the diet of the Black Heron *Ardea melanocephala*. Ectoparasites include at least eight species of fleas and three species of ticks. Whistling rats are susceptible to natural outbreaks of plague, making them important vectors of the disease (De Graaff 1981, and references therein).

Conservation IUCN Category: Least Concern.

Parotomys littledalei LITLEDALÉ'S WHISTLING RAT

Fr. Rat de Littledale; Ger. Littledales Pfeifratte

Parotomys littledalei Thomas, 1918. Ann. Mag. Nat. Hist., ser. 9, 2: 205. Kenhardt, Northern Cape Province, South Africa.

Taxonomy Synonyms: *molopensis*, *namibensis*. Subspecies: none. Chromosome number: 2n = 50 (Meester 1988).

Description Medium- to large-sized rat with blunt head and dark tail. Pelage soft and long (up to 13 mm). Dorsal pelage cinnamon-buff; hairs medium grey at base, cinnamon-buff at tip; long pure black hairs, especially on mid-dorsal line. Flanks and ventral pelage pale buff; hairs grey at base, buff or off-white at tip. Head with blunt muzzle, similar in colour to back, without russet on forehead and nasal region. Ears large and rounded, darkly pigmented, covered with short yellowish hairs. Limbs short. Forefeet with four long digits and long slender claws. Digit 1 reduced, hardly visible; hindfeet with five well-developed digits and long slender claws, all digits well covered with short off-white hairs. Tail short (ca. 70% of HB), covered with hair, dark buff above, paler below; tip may be black. Skull: upper and lower incisors without grooves. M³ with three laminae. Nasal bones moderately expanded. ♂♂ on average larger than ♀♀ for most measurements. Vocalizes using a single, high-pitched, alarm whistle of approximately 0.5 sec in duration (Le Roux *et al.* 2002). Nipples: 0 + 2 = 4.

Geographic Variation Mean HB and weight of individuals in South Africa are greater than those in Namibia (although tails are shorter), and ♂♂ are also larger than ♀♀, e.g. in South Africa: ♂♂ – HB: 238 (176–276) mm, T: 100 (78–118) mm, WT: 120 (72–153) g; ♀♀ – HB: 222 (205–246) mm, T: 92 (79–107) mm, WT: 95 (80–116) g (T. Jackson unpubl.) (see also Measurements).

Similar Species

P. brantsii. HB similar; often weight heavier; nose and ears more rounded; each upper incisor with two grooves; M³ with two laminae. Alarm whistle longer with a higher dominant frequency of 10 kHz.

Distribution Endemic to Africa. South-West Arid BZ (Namib Desert and Karoo). Recorded from the coastal areas of N Namibia to the Western and Northern Cape Provinces, South Africa. Absent from the central Namib Desert.

Habitat Coastal hummocks, sand dunes and gravel plains of the Namib Desert, and (dry) riverine systems extending inland from the coastal plains of Namibia (Coetzee 1969, Coetzee & Jackson 1999).

Parotomys littledalei

Abundance Comparatively common in suitable habitat (although infrequently caught using small rodent traps). Avoids open habitats. Rarely seen but frequently heard.

Adaptations Diurnal and terrestrial. In Namaqualand, lives in moderate-sized burrows extending over an average of 4.7 m², with an average of eight entrances. Burrows are constructed below bushes and contain several nest chambers filled with shredded vegetation (Jackson 2000a). Burrows are linked by surface pathways. Littledale's Whistling Rats show several physiological adaptations to reduce water loss: the large kidneys (1.4% of body mass compared with 0.6% in *P. brantsii*) enable production of the most concentrated urine of any southern African otomyine rodent (Jackson *et al.* 2004); and the long intestine (proportionately the longest large intestine of any southern African otomyine rodent [Jackson & Spinks 1998]) probably enhances water absorption. Exhibits hyperthermia at ambient temperatures higher than 31 °C, although in this respect thermophysiology does not differ markedly from otomyine rodents inhabiting more mesic habitats (Jackson *et al.* 2004).

A high-pitched alarm whistle (dominant frequency 7.7 kHz, duration 53 ms; Le Roux *et al.*, 2002) is emitted when disturbed by predators. No other vocalizations as yet recorded.

Foraging and Food Exclusively herbivorous, feeding on a variety of fresh plant material including annuals, succulent perennials, non-succulent perennials and grasses. Feeds under the cover of bushes, where runways link foraging areas to burrows. In some areas, probably feeds only on one plant species such as *Salsola nollothensis*, due to lack of variety of available plants (Coetzee & Jackson 1999). In coastal Namibia, the diet includes *Tribulus zeyheri*, *Psilicaulon salicornioides*, *Atriplex lindleyi*, *Lycium tetrandum*, Aizoaceae spp. and *Salsola* sp. Fresh plant cuttings, including *Lycium* sp., *Schismus inermis*, *Psilicaulon absimile*, *Messembryanthemum guerichianum* and *Galenia sarcoophylla* have been collected at burrow entrances in Namaqualand, indicating that these species are included in the diet (T. Jackson, unpubl.).

Social and Reproductive Behaviour Individuals inhabit burrows built at the base of bushes (e.g. *Psilicaulon absimile*, *Atriplex ganescense*, *Salsola* sp., *Zygophyllum stapffii*, *Lycium tetrandum*) in suitable habitat. Whilst small bushes probably include the burrows of single individuals, burrows under large bushes may be occupied by several individuals (Coetzee & Jackson 1999). Social organization probably parallels that of *P. brantsii*, with individuals maintaining separate territories within a bush.

Reproduction and Population Structure Reproductive activity is related to rainfall. In Namibia, reproductively active ♀♀ caught during the period of summer rainfall (Sep–Mar). In contrast, in Namaqualand, 75% (n=4) of ♀♀ were lactating in Sep following the winter rainfall, and none was reproductively active in Apr (n=4) prior to rain. Gestation: 41 days. Embryo number: 2.4 (1–3; Namibia; Coetzee & Jackson 1999). Litter-size (in captivity): 2.4 (2–3; Pillay 2002). At birth, young precocial, eye slits visible, incisors erupted; mean weight 12.7 g. Sense of smell developed by Day 4. Auditory meatus and eyes open Day 4–6. Weaned Day 8–12, when mean weight 38.4 g (Pillay 2002). Sexual maturity: 6 weeks (♂♂), 5 weeks (♀♀).

Predators, Parasites and Diseases Remains recorded from the pellets of Pale Chanting Goshawks *Melierax canorus* (G. Malan unpubl.). Judging by their hunting activity, other potential predators include Yellow Mongooses *Cynictis penicillata*, African Wild Cats *Felis lybica* and Jackal Buzzards *Buteo rufofuscus*. Ectoparasites include eight species of fleas and one species of mite (De Graaff 1981, and references therein).

Conservation IUCN Category: Least Concern.

Family ANOMALURIDAE

ANOMALURES

Anomaluridae Gervais, 1849. In: D'Orbigny, Dict. Univ. Hist. Nat., 11: 203. f

| | | |
|-------------------------------|--------------------|--------|
| <i>Anomalurus</i> (4 species) | Anomalures | p. 603 |
| <i>Idiurus</i> (2 species) | Pygmy Anomalures | p. 611 |
| <i>Zenkerella</i> (1 species) | Cameroon Anomalure | p. 615 |

The family is endemic to Africa, and comprises three genera and seven living species. All living anomalures are restricted to the Rainforest BZ, with the single exception of *Anomalurus derbianus*, which also occurs in well-developed woodlands where trees of the family Caesalpiniaceae are either dominant or abundant.

The most obvious feature of all anomalures (with the exception of *Zenkerella insignis*) is the presence of a patagium (or flight membrane) stretched between each forelimb and hindlimb, from wrist to ankle, and a smaller interfemoral patagium (or tail membrane) between each hindlimb from the ankle to the proximal end of the tail. A cartilaginous spur, the calcaneum, supports the anterior part of each patagium between the elbow and outer edge of the patagium. The patagia, when stretched, form an aerofoil that enables the anomalure to glide from tree to tree. The patagia cannot be flapped (as for the wing of a bird or bat). Dorsal pelage colour is greyish, brownish or black, frosted with white in some species, and the ventral pelage is pale or whitish. Pelage colour in *Anomalurus* spp. (except *A. pusillus*) varies geographically, the proportion of the various colour morphs varying in different parts of the geographic range (Schunke & Hutterer 2004). The tail is long and well covered with hair, but the hairs are not as long or as bushy as in squirrels, except for the last third of the tail. On the undersurface of the tail, near the base, are two rows of scales; the scales overlap slightly and each scale has a posteriorly directed sharp point. The scales are used for supporting the body when resting or when climbing the vertical trunk of a tree. There are four digits on the forefoot and five digits on the hindfoot; all digits have long curved pointed claws. The head has large eyes, relatively large ears and well-developed vibrissae. *Zenkerella insignis* does not have patagia and is unable to glide.

The skull is diagnostic and shows many differences from the skull of squirrels (family Sciuridae). The postorbital process is small or absent (well-developed in squirrels), the infraorbital foramen is large and contains a very large masseter muscle (very small in squirrels), the zygomatic arches are curved outwards so the head has a rounded appearance (not markedly curved and head narrower in squirrels), and the palate is narrow, especially at the level of the single premolar

(P⁴) and M¹, becoming broader posteriorly as the line of cheekteeth curves outwards (also broad in squirrels, and of similar width along its length between the parallel rows of cheekteeth). The posterior surface of the incisors is smooth (*Anomalurus*, *Zenkerella*) or notched (*Idiurus*). Dental formula: I ¹/₁, C ⁰/₀, P ¹/₁, M ³/₃ = 20 (as in Sciuridae – squirrels). Size categories of species in the family (based on mean head and body length) are given in the order Rodentia profile.

Anomalures are arboreal and scansorial, and occasionally terrestrial. They are nocturnal, resting during the day in hollows and cavities of large trees. Before gliding, an individual climbs up a tree with a 'humping gait', the two forefeet alternating with the two hindfeet. It launches itself into the glide with the limbs spread-eagled so the patagia are extended to form a taut aerofoil (or a curved umbrella-shaped structure – Sanderson 1940). Before landing – at a lower elevation from where the glide began – the anomalure assumes a vertical position; on landing, the long claws on the digits and the pointed scales on the undersurface of the tail securely grip the trunk of the tree. By climbing up trunks and gliding from tree to tree, an anomalure can move easily throughout its home-range in the forest. Anomalures are vegetarians, feeding on leaves, fruits, seeds, nuts, bark and phloem exudates. Little is known about their reproductive biology, other than that litter-size is usually one. Longevity in the wild is unknown.

The seven living species of Anomaluridae represent specialized vestiges of an ancient, uniquely African group of rodents that were diverse (20 genera) and abundant in the Oligocene (36.6–23.7 mya). This diversity would seem to have disappeared under the competitive influence of other families of rodents, which invaded from Eurasia in the Miocene and later. The anomalures have evolved independently in Africa from the ecologically equivalent gliding rodents of Eurasia and the Americas and from gliding marsupials in Australia. Their survival would seem to be based upon their having adopted successful gliding niches before any other incoming rodents could compete.

The living Anomaluridae have some very distant relationship with the Springhares, family Pedetidae. Presumably both derive from a very ancient and primitive type of anomalurid. Because fossil anomalurids were diverse and abundant before Africa's reconnection with the Eurasian land mass it is likely that they evolved from a primitive rodent group that became established in Africa during the long isolation of Africa during the Palaeocene and Cretaceous.

Table 43. Species in the family Anomaluridae.

| Species | Patagium | Eye-mask | HB mean (range) (mm) | T mean (range) (mm) [% of HB] | GLS mean (range) (mm) | Dorsal pelage | |
|-----------------------------|----------|----------|----------------------|-------------------------------|-----------------------|----------------------------|--|
| <i>Anomalurus derbianus</i> | Present | Present | 306 (283–379) | 284 (227–327) [90%] | 58.7 (57.8–60.2) | Grey, reddish, or brownish | |
| <i>Anomalurus pelii</i> | Present | Absent | 421 (400–460) | 403 (325–450) [95%] | 67.8 (65.5–69.5) | Black | |
| <i>Anomalurus beecrofti</i> | Present | Absent | 278 (261–300) | 213 (190–238) [75%] | 56.3 (53.8–58.8) | Grey, silvery-grey | |
| <i>Anomalurus pusillus</i> | Present | Absent | 231 (221–238) | 136 (130–140) [60%] | 44.4 (43.8–44.8) | Blackish-tan (flecked) | |
| <i>Idiurus macrotis</i> | Present | Absent | 88.4 (73–105) | 132.4 (110–186) [150%] | 26.1 (25–27) | Sepia-grey | |
| <i>Idiurus zenkeri</i> | Present | Absent | 69.5 (63–75) | 94.9 (83–104) [130%] | 20.9 (20.4–22.0) | Brown | |
| <i>Zenkerella insignis</i> | Absent | Absent | 202.7 (180–225) | 172.5 (165–180) [85%] | 45.7 (44.8–46.3) | Slate-grey | |

Although the Anomaluridae have traditionally been placed next to the Sciuridae in the suborder Sciurognathi of the order Rodentia (Wilson & Reeder 1993, Rosevear 1969), or as the sole representative of the superfamily Anomalurioidea in the ‘Sciuromorpha’ (Anderson & Jones 1984), new phylogenetic analyses using morphological and mitochondrial genes suggest that the Anomaluridae and Pedetidae form a suborder Anomaluromorpha in the order Rodentia (Montgelard *et al.* 2001, 2002, Huchon *et al.* 2002). Thus the family is no longer associated closely with the Sciuromorpha

(squirrels and their relations) (Musser & Carleton 2005) but is associated in a way not yet fully comprehended or acknowledged with the Pedetidae.

The three genera (*Anomalurus*, *Idiurus* and *Zenkerella*) and six species (Table 43) are distinguished by the size of the body and hindfoot, the presence/absence of patagia, the form of the tail and the shape and position of the maxillary branch of the maxillary process.

Jonathan Kingdon

GENUS *Anomalurus*
Anomalures (Scaly-tailed Squirrels)

Anomalurus Waterhouse, 1843. Proc. Zool. Soc. Lond. 1842: 124 (1843). Type species: *Anomalurus fraseri* Waterhouse, 1843 (= *Pteromys derbianus* Gray, 1842).

Anomalurus pusillus.

The genus contains four species, all of which live in the rainforests of West and central Africa. Species in the genus are characterized by extensive flight patagia on either side of the body between long, very lightly built limbs; and small interfemoral patagia between the hindlimbs and the proximal end of the tail. The undersurface of the basal part of the tail bears two rows of closely packed, sharply pointed scales; hence the alternative vernacular name ‘scaly-tail’. A cartilaginous spur on the elbow provides support for the flight membrane. The species of *Anomalurus* are large and heavy, with a long

Figure 95. Skull and mandible of *Anomalurus derbianus* (BMNH 64.1075). Angular process of mandible broken; details added from Ellerman (1940) and other specimens.

| | Distribution and Notes |

tail ending in a well-developed brush (cf. *Idiurus*). On the skull, the posterior surface of each upper incisor is smooth without a notch (cf. *Idiurus*), the lower branch of the maxillary process is immediately anterior to M¹ (cf. *Idiurus*, *Zenkerella*), and the nasal bone is comparatively shallow (cf. *Idiurus*, *Zenkerella*) (Figure 95). The skulls of each species of *Anomalurus* are very similar morphologically, but differ in size. See also Family profile.

One species, *A. beecrofti*, has sometimes been allocated to a distinct genus or subgenus, *Anomalurops*, because of its narrower skull and differences in dentition compared with *Anomalurus* (e.g. Rosevear 1969, Grubb *et al.* 1998).

Anomalurus beecrofti BEECROFT'S ANOMALURE (BEECROFT'S SCALY-TAILED SQUIRREL)

Fr. Anomalure de Beecroft; Ger. Beecrofts Dornschwanzhörnchen

Jonathan Kingdon

Anomalurus beecrofti Fraser, 1853. Proc. Zool. Soc. Lond. 1852: 17. 'Fernando Po' (= Bioko I., Equatorial Guinea).

Taxonomy This species has been separated from the other large anomalures into the genus *Anomalurops* (Matschie 1914, Rümmler 1933, Dekeyser 1955, Rosevear 1969) on the basis of many skull characters including narrower zygomatic width, wider frontals between the orbits, more inflated auditory bullae, nasal bones, which extend well forward of the incisors, wedge-shaped palate due to the pronounced out-curving of the cheekteeth row at the rear of the palate, specialized palate and muzzle that are exceptionally narrow, and unusual dentition (see Description). Recent authors (e.g. Dieterlen 1993a, 2005a) have retained *A. beecrofti* in the genus *Anomalurus*, although it is possible that further studies of its anatomy, behaviour and genetics may justify the validity of the genus *Anomalurops* (see Rosevear 1969 for additional comment).

A large number of forms have been described. Some of these may reflect regional differences; Rosevear (1969), in comparing the types of *argenteus* and *citrinus*, stated that although they are different, these forms are extremes and that many intermediate forms exist. The form *schou tedeni* was considered a valid species by Crawford-Cabral (1971), and *fulgens*, from Gabon, has been treated as a full species by some authors (e.g. Dorst & Dandelot 1970, Haltenorth & Diller 1980) because of its entirely orange pelage; however, yellowish or orange tints are characteristic of most populations and are probably poor criteria for erecting taxa. Indeed, Rosevear (1969) was of the opinion that *fulgens* was little more than an erythristic form. Schunke & Hutterer (2004) showed that the species is polymorphic, with different proportions of each colour morph in different populations, and hence subspecies are not recognized. Synonyms: *argenteus*, *chapini*, *citrinus*, *fulgens*, *hervoi*, *laniger*, *schoutedeni*. Subspecies: three of dubious validity (but see Geographic Variation). Chromosome number: not known.

Description Very large arboreal rodent with well-developed patagia and long narrow tail. Pelage colour varies geographically (see below). Dorsal pelage soft, long and dense, agouti grey or silvery-grey often with golden-brown stripe from neck over larger part of back, or wholly orange, or without any orange colouration. Ventral pelage pale grey or orange with yellow/orange mid-ventral stripe, or uniformly orange, or grey without yellow mid-ventral stripe; ventral hairs less dense than on dorsal pelage. Dorsal surface of flight patagia

At least one species of *Anomalurus* is of great ecological interest for its possible influence on forest dynamics. Sustained 'pruning' by *A. derbianus* of vegetation around their food trees may favour the survival of preferred food trees; this may determine (in the long term) the composition of rainforest plant communities by favouring some species of trees at the expense of other species.

The species are distinguished by size of head and body, size of skull, and the colour of pelage and tail.

grey or brown; interfemoral patagia grey or ochre (similar to dorsal pelage). Ventral surface of patagia ochre-yellow, less densely haired than dorsal surface. Cartilaginous spur projects outwards (within the membrane) from the elbow to margin of patagium. Head somewhat narrower, with longer muzzle, than in other *Anomalurus* spp. Face pale coloured (grey or yellowish) without dark 'eye-mask' around the eyes. Many individuals have a small white spot on the upper forehead. Ears pale, narrow and somewhat pointed, bordered by an arc of black hairs on the temple. Vibrissae clustered on densely haired and swollen pads of the upper lips. Chin and top of the head with shorter, finer individual vibrissae. Upper surfaces of limbs grey (as dorsal pelage). Digits with long sharp claws. Tail short (ca. 75% of HB), with sparse short grey hairs; very small whitish brush at tip; up to nine pairs of sharp pointed scales on ventral surface near base of tail near where it becomes free of the interfemoral patagia. Skull similar to *A. derbianus* but with very narrow palate (especially at level of P⁴ and M¹), narrow cheekteeth (<3 mm), nasal bones that project well forward of the incisors, cheekteeth row slightly curved outwards, and larger auditory bullae. Nipples: 1 + 1 = 4 (or 2 + 0 = 4).

Geographic Variation Dorsal and ventral colouration is polymorphic and varies geographically and within populations (see Schunke & Hutterer [2004] for details, and Rosevear [1969] for further comment). Three subspecies have been recognized (as given below), but the presence of different colour forms within single populations suggests that the subspecies are perhaps invalid.

A. b. beecrofti: Bioko I. Dorsal pelage dark brown or golden-brown, without any orange colouration; ventral pelage pale orange, or grey with central orange stripe.

A. b. argenteus: Sierra Leone to Cameroon. Dorsal pelage silvery-grey with golden-brown mid-dorsal stripe (sometimes absent); ventral pelage pale grey or yellowish with or without central yellow stripe.

A. b. fulgens: Gabon. Dorsal pelage orange; ventral pelage grey with orange, or wholly orange.

Similar Species

A. pusillus. Smaller, dorsal pelage relatively uniformly brownish; tail black-tipped and bushy.

A. derbianus. On average larger, eye-mask, muzzle and surroundings of ear black or brown; tail black and bushy.

Distribution Endemic to Africa. Rainforest BZ (all regions) and Southern Rainforest–Savanna Mosaic. Widely distributed from Senegal, Guinea-Bissau and Sierra Leone (though not yet known from Gambia) to E DR Congo and throughout the Rainforest BZ north and south of the Congo R. Also relict forests in Angola and NW Zambia, Bioko I., reliably reported from Bwamba, W Uganda. Altitudinal range: near sea level to 2500 m.

Habitat Preferred habitats are swamp forests with abundant wild palms; there is a close correspondence between the natural distribution of the oil palm (*Elaeis guineensis*) and this anomalure. Also recorded from cultivated areas, notably oil palm plantations.

Abundance Uncertain, but may be comparatively common in suitable habitats. Individuals are difficult to observe (due to their exceptional powers of concealment). Lack of observations may reflect low densities, even in suitable habitat.

Adaptations Arboreal and mostly nocturnal. Beecroft's Anomalures are considered to be wholly nocturnal (Dekeyser & Villiers 1951), although some authors (e.g. Sanderson 1940) have suggested they are diurnal perhaps because they have been seen resting on tree trunks during the day (something almost unknown in Lord Derby's Anomalure, *Anomalurus derbianus*). In such situations, their mottled agouti pattern seems to represent an effective camouflage against predators. Although recorded from areas with tall trees, this species appears to be less dependent than other *Anomalurus* spp. on long, unobstructed flight paths.

Sanderson (1940) reported that Beecroft's Anomalures prefer the upper strata of forest and sleep in dense conglomerations of leaves and twigs at the very summits of trees. One individual has been

observed asleep at 08:00h clinging to the trunk of a palm tree, more than 6 m up, under the shelter of a dead frond (T. S. Jones in Rosevear 1969). These and other reports of opportunistic roosting in relatively exposed temporary sites suggest that Beecroft's Anomalure may be considered to be much more of a 'camper' than other anomalures.

Branch pruning, as practised by *A. derbianus*, has not been recorded but some twig cutting is likely to occur. The narrower, more elongated muzzle and narrow incisors probably constrain its foraging to only the slenderest twigs. Moving between short-trunked, swamp forest trees that are quite close together, among sprays of palm fronds and across obstructed spaces poses many problems for a glider and suggests that *A. beecrofti* may scramble through vegetation more than other anomalures. How its gliding differs from the commoner *A. derbianus* is not known, but its smaller size and weight probably help while the long, whippy tail is generally concerned with maintaining balance. The special significance of its elongated and slightly down-turned, tubular nose is not known but could suggest that the scent of foods can be very closely monitored while being gnawed.

Foraging and Food Little known. Reported to feed on various fruits, bark, leaves, flowers and occasional insects, but some authors (Dekeyser & Villiers 1951) have found they feed only on the pulp of oil palm fruits, *Elaeis guineensis*. Although ripening bunches of oil palm fruits are protected by short spines, the anomalures mainly chew the pulp *in situ* (Dekeyser and Villiers 1951). The special problems associated with getting at the pulp of palm fruits growing in large, densely packed bunches might favour a narrow muzzle, permitting the incisors to reach deeper into the spaces between hard-stoned fruits.

Social and Reproductive Behaviour Because the few records have always been of single individuals, they have been assumed to be solitary. Information is lacking on territoriality, interactions between individuals and on social organization. The only known vocalization (Bates 1905) is a low noise in the forest at night characterized as something between a whistle and a hoot.

Reproduction and Population Structure In Ibadan, Nigeria, two ♀♀, each with a small young, were obtained in early Oct and late Jan (Happold 1987). In Cameroon, a pregnant ♀ was found in Jul (Sanderson 1940).

Predators, Parasites and Diseases Alp & Kitchener (1993) recorded a jaw fragment of this species in faecal remains from a Robust Chimpanzee *Pan troglodytes* in the Tenkere area of Sierra Leone. Other potential predators include Crowned Eagles, Long-tailed Hawks and pythons. A microfilaria has been reported from the blood of West African specimens (Dekeyser & Villiers 1951).

Conservation IUCN Category: Least Concern.

Possibly declining locally but still widespread. These anomalures are too small and rare to warrant being hunted for food. Although they are known to feed on oil palm fruits, they are unlikely to represent any threat to oil palm production.

Anomalurus derbianus LORD DERBY'S ANOMALURE (LORD DERBY'S SCALY-TAILED SQUIRREL)

Fr. Anomalure de Derby; Ger. Derbys Dornschwanzhörnchen

Anomalurus derbianus (Gray, 1842). Ann. Mag. Nat. Hist., ser. 1, 10: 262. Sierra Leone.

Taxonomy Originally described in the genus *Pteromys*. Validity of the specific name *derbianus* is questioned by Rosevear (1969) as it antedates *Anomalurus fraseri* Waterhouse 1842 from Bioko, Equatorial Guinea (now considered a synonym of *derbianus*). The type specimen is in very poor condition and without skull. Considerable variability in pelage colour within and between populations. Synonyms: *beldeni*, *chrysophaenus*, *cinereus*, *erythronotus*, *fortior*, *fraseri*, *griselda*, *imperator*, *jacksoni*, *jordani*, *laticeps*, *neavei*, *nigrensis*, *orientalis*, *perustus*, *squamicaudus*. Subspecies: at least 15 subspecies have been described, none of which is recognized now. Chromosome number: not known.

Description Very large anomalurid with dark grey, long, fine-textured fur with silvery grizzle. Dorsal pelage long, dense and fine in texture, greyish or brownish to reddish-brown; hairs dark grey at base with subterminal ring and inconspicuous black tip, giving dorsal pelage a somewhat mottled appearance (see also Geographic Variation). Hairs silver-tipped around head and shoulders. Ventral pelage dense, pure white, greyish or yellowish. Flight patagia stretch between forelimb and hindlimb, and interfemoral patagia are present between the ankle and the proximal end (ca. 5 cm) of the tail. Cartilaginous spur projects outwards (within the membrane) from the elbow to margin of patagium. Hairs on membrane similar in colour to dorsal pelage but shorter and sparser; ventral surface almost naked. Roundish head with relatively short, pointed muzzle and large eyes. Black mask surrounds eyes and ears; forehead and throat almost uniformly pale grey. Ears large, elliptical, erect and naked, surrounded at bases with long back hair. Limbs long, feet powerfully built. Forefeet have four digits, hindfeet have five digits, all with thin, strong, sharp, curved claws. Upper surface of feet covered with hairs; black bristles cover hindclaws. Tail long (ca. 90% of HB), narrow, short-haired at base widening to long-haired brush at tip; basal portion pale turning to black distally; strong, pointed scales on basal ventral surface of tail. Skull with narrow palate, narrow cheekteeth (<3 mm), lower branch of maxillary process ending just anterior to first cheektooth, molar row slightly curved outwards, three depressions between transverse enamel ridges of each cheektooth, and without a sharp, backward pointing postero-internal cusp on each molar. Nipples: 2 + 0 = 4.

Geographic Variation Dorsal colouration is polymorphic and varies geographically and within populations; the brownish colour morph is usually the commonest colour in all populations. From S Cameroon to the lower Congo and Ubangi rivers, the dorsal colour

Anomalurus derbianus

of most individuals is reddish-brown (although some 'brownish' individuals are also present) and the patagia are grey. In SE DR Congo and S Tanzania, some individuals have silvery-grey dorsal pelage. Ventral colouration is usually white or greyish; in some populations, some individuals are yellowish mixed with grey (C DR Congo and Zambia) and some are pale yellow (Kenya). The colour of ear, throat and shoulders also exhibits inter- and intra-population variation (details in Schunke & Hutterer 2004).

Similar Species

A. beecrofti. On average smaller; ear shorter; tail with very small terminal brush; snout narrow and pointed; pelage somewhat longer, softer and sometimes darker.

Distribution Endemic to Africa. Rainforest BZ (all regions), Rainforest–Savanna Mosaics, and northern parts of Zambezi Woodland BZ. Recorded from Sierra Leone to W Kenya, and from N Angola, S DR Congo, Zambia, N Malawi, and S and N Tanzania. Two records in N Mozambique (Smithers & Wilson 1979). Zanzibar I. (requires confirmation).

Habitat Catholic in habitat requirements as long as forest cover is adequate and naturally hollow trees are present for resting and nesting. Found in broad spectrum of forest types, ranging from moist rainforest to savanna woodlands, from sea level to 2400 m (Rahm 1969b, Rosevear 1969, Jones 1971, Kingdon 1974, Grubb *et al.* 1998). May prefer relatively open forest with well-spaced tree trunks and scarce vines (Happold 1987). While abundant in relatively undisturbed forest, also found nesting in dead standing trees in burned areas cleared for cultivation and near villages (Rahm 1969b, Jones 1971), provided living trees are within gliding distance (Rosevear 1969).

Abundance Commonest of the larger anomalurids (Rosevear 1969). Estimated density in central Gabon 27–54 individuals/km²; biomass 30–65 kg/km² (Julliot *et al.* 1998). Most abundant of three anomalurids in E DR Congo, representing 60% of 30 individuals collected (Rahm 1969b).

Adaptations Nocturnal and arboreal. Usually rests during day unless disturbed, and regularly emerges from resting areas shortly after dusk (Rosevear 1964, Rahm 1969b, Jones 1971, Julliot *et al.* 1998). Marked individuals in central Gabon began activity as soon as the light level in the forest became low (18:10–18:55h; *n* = 27) and returned to the nest at sunrise (05:20–06:20h; *n* = 14). During night, no clear pattern of activity was exhibited (Julliot *et al.* 1998).

Derby's Anomalures are almost completely arboreal, rarely venturing to the ground. Individuals rest while clinging to sides of trees, 8–25 m above the ground, with the head up and body parallel to the bole. The long sharp claws grip the bark, and the scales on the undersurface of the tail also provide support (Rosevear 1969). Gliding is performed with the patagia outstretched, and the distance that can be covered is determined by gravity and the height at take-off. The patagia do not flap during gliding and have very limited manipulability, and hence a glide ends at a lower level to where it began. Observations on two individuals in Tanzania recorded the downward glide angle (from the horizontal) as 24 degrees, regardless of the height above the ground where the glide began and the length of the glide (animal 1: horizontal glide distance 4.5 m; glide distance 5.4 m; glide from 5 m to 3 m above ground; animal 2: horizontal glide distance 40 m; glide distance 44 m; from 23 m to 4.5 m above ground) (Corbin & Cordeiro 2006). The glide angle of 24 degrees is probably the most efficient angle that allows for the longest glide distance; the morphology of the pelvis (Scheibe & Essner 2000) and large thigh muscles (Kingdon 1974) contribute to the ability of the anomalure to 'leap' into the glide rather than 'dropping' before 'gliding'. On landing on a tree trunk (fore- and hindlimbs landing at the same time, with the body almost vertical), the anomalure climbs up immediately with a 'humping gait', forefeet alternating with hindfeet, to gain height once again (Rosevear 1969). Anomalures can glide up to 50 yards (Rosevear 1969) and sometimes up to 100 m (Kingdon 1974). One radio-collared ♀ covered an average distance of 540 m per night, alternating between localized movements and directed glides up to 100 m (Julliot *et al.* 1998). Anomalures are awkward and clumsy on the ground, heading immediately for a vertical surface in a series of jumps if disturbed. They ascend trees and vertical structures rapidly (Rahm 1960a, Rosevear 1969). Further details of gliding are given by Rahm (1969b), Rosevear (1969) and Sanderson (1940).

Rests during the day in nests within hollows, often in trees that have lost their crowns and are open at the top (Rahm 1960a, 1969b, Jones 1971, Julliot *et al.* 1998). The size and species of tree do not seem to be important in nest selection – more important is the position and quality of the entrance hole. In C Gabon, primary nests (80%; *n* = 10) had both basal and high entrance holes, while secondary nests had high entrance holes only (Julliot *et al.* 1998). In Equatorial Guinea, hollows where nests were situated ranged from 0.3 to 2.5 m diameter and up to ca. 40 m above the ground (Jones 1971). One radio-collared female in Gabon used six nesting trees, one primary and five secondary. Individuals apparently exhibit some degree of fidelity to nests, with the same ♀ using the same nest for four months (Julliot *et al.* 1998). Fidelity to a particular nest was observed in E DR Congo, where the same individual is thought to occupy the same nest for at least 2.5 years (Rahm 1969b).

Like other anomalures, Derby's Anomalure engages in pruning behaviour, using its incisors to clear bark and cut small branches. This branch-cutting behaviour is thought to enhance access to food supplies and also keep flight paths open (Kingdon 1997).

Colour and markings of the pelage blend well with the background of a tree where an individual may sun itself during the day (Rosevear 1969, Kingdon 1974), although well-lit resting places are avoided (Julliot *et al.* 1998). Anomalures have powerful jaw musculature for gnawing bark or chewing woody twigs. Large ears with well-developed auditory bullae suggest that hearing plays a large role in sensory perception (Rosevear 1969). Structure of the male penis was described as 'remarkable' by Sanderson (1940), who noted the presence of a cartilaginous 'spear'.

Foraging and Food Wholly vegetarian; diet consists of leaves, fruits, flowers and soft inner bark (Rahm 1960a, Rosevear 1969). In C Gabon, anomalures forage by scratching bark of trees (mostly of the family Caesalpiniaceae) with the teeth, cutting the bark open, licking exuding material and ingesting the phloem sap (but not the bark itself). Stomach contents of one individual consisted of leaves and petioles, bark fragments, and ants and termites (Julliot *et al.* 1998). Other records indicate actual ingestion of bark and/or gnawing of twigs and branches (Rahm 1960a, Kingdon 1974). In E DR Congo, individuals have been observed feeding on fruits and leaves and inner bark, while avoiding trees that exude latex (Rahm 1960a). Flowers and fruits are thoroughly masticated (Sanderson 1940).

Social and Reproductive Behaviour Nests usually contain a single individual (*n* = 6 out of 10) but up to three individuals have been found in nests in central Gabon. Except for mother/young pairs, individuals enter and leave nests individually. Two individuals (other than mother/young) may feed close together, and one may glide after the other (Julliot *et al.* 1998). In Equatorial Guinea, Jones (1971) found 1–3 individuals resting in tree hollows (*n* = 10 trees). Larger groupings have also been recorded (Rosevear 1969, Kingdon 1974). Known to share the same hollow occasionally with bats and other species of anomalures (Julliot *et al.* 1998). Home-range of a radio-collared ♀ in C Gabon was 3.37 ha, with 50% of locations in a small central area comprising 11.3% of home-range (Julliot *et al.* 1998).

Reproduction and Population Structure One to three young (Sanderson 1940, Kingdon 1974) have been recorded. Mother/young observations in C Gabon were all of single young (Julliot *et al.* 1998). In Equatorial Guinea, lactating ♀♀ were collected in Feb and May (Jones 1971). In S Cameroon, pregnant ♀♀ were collected in the beginning of the wet season (Jun/Jul) (Sanderson 1940). In Uganda and W Kenya, four births were recorded in Jan, two pregnancies in Mar and a lactating mother in May. In S Tanzania, well-grown young were observed in May/Jul corresponding with the early dry season (Kingdon 1974). Young are born in nests in hollow trees, and at birth are large, well-furred and the eyes are open (Kingdon 1974). Vagina of pregnant ♀♀ sealed with hard plug (Sanderson 1940).

Predators, Parasites and Diseases In C Gabon, one record of predation by an eagle (Julliot *et al.* 1998). A Blue Monkey *Cercopithecus mitis* in Budongo Reserve, Uganda was seen feeding on a Derby's Anomalure during the dry season when food availability is generally at its lowest (Fairgreave 1997). Rahm (1969b) noted the tendency of some people of E DR Congo to season food with the aromatic gut contents of Derby's Anomalures. A species of malarial plasmodium has been found in some specimens (Kingdon 1974).

Conservation IUCN Category: Least Concern.

Listed under CITES Appendix III in Ghana. Otherwise considered to be the most widely distributed and tolerant of the anomalures (Kingdon 1974). Deforestation constitutes an on-going threat to the survival of some populations.

Justina C. Ray

Anomalurus pelii PEL'S ANOMALURE (PEL'S SCALY-TAILED SQUIRREL)

Fr. Anomalure de Pel; Ger. Pels Dornschwanzhörnchen

Anomalurus pelii (Schlegel & S. Müller, 1845). In: Temminck (1843–1845): Verh. Nat. Gesch. Nederland. Overz. Bezitt., Zool., Mammalia, p. 109. 'Daboerom, aan de Goudkust' (= Dabacrom, Ghana).

Taxonomy Originally described in the genus *Pteromys*, a genus of 'flying squirrels' (Sciuridae, Petauristinae) that occurs only in the Palearctic. Synonyms: *auzembergeri*, *peralbus*. Subspecies: three. Chromosome number: not known.

Description Very large anomalure, usually with fringe of white hairs around the edges of the patagia, and a black or white tail. The largest species of anomalure. Pelage soft and long; colour varies geographically; description for *A. p. pelii* follows (but see Geographic Variation for other subspecies). Dorsal pelage pure black, with narrow band of white around edge of flight patagia and interfemoral patagia. Ventral pelage grey or off-white; less dense than dorsal pelage. Cartilaginous spur projects outwards (within the membrane) from the elbow to margin of flight patagium. Head black with large white nose-spot. Vibrissae long, black, growing from black-furred pads on upper lips and muzzle. Ears large, rounded at tip, with pale pigmentation and conspicuous dense tuft of white hairs along dorsal margin. Forelimbs with four digits, black above, pale below, and well-developed narrow short claws. Hindlimbs with five digits, black above fringed with white (where patagium joins limb), pale below; well-developed claws. Tail long (ca. 95% of HB), pure white (*peralbus*, *pelii*) or black (*auzembergeri*), well covered with rather coarse hairs; hairs short near base, becoming longer towards tip and forming large brush

at terminal end; 6–7 pairs of sharp pointed scales on ventral surface near base of tail near where it becomes free of the patagium. Skull similar to *A. derbianus*, but larger in all dimensions. Nipples: 2 + 0 = 4.

Geographic Variation Rosevear (1969) detailed two subspecies (*A. p. auzembergeri* and *A. p. pelii*). Schunke & Hutterer (2005) reviewed colour variation in the species and described a third subspecies (*A. p. peralbus*).

A. p. peralbus: Côte d'Ivoire, between Bandama and Sassandra rivers; flight patagia with very wide white border on dorsal surface, reaching almost to the body; wide white border on interfemoral membrane; tail white; large white patch at base of each ear; fore- and hindfeet white.

A. p. pelii: Côte d'Ivoire (east of Bandama R.) and Ghana (west of Volta R.); flight patagia with narrow white border on dorsal surface; narrow white border on interfemoral membrane; tail whitish; white patch at base of each ear; forefeet blackish and hindfeet whitish (see Rosevear 1969 for colour picture).

A. p. auzembergeri: Côte d'Ivoire (west of Bandama R.) and Liberia; flight patagia black without any white border on dorsal surface; interfemoral membrane black without white border; tail black; without white patch at base of each ear; fore- and hindfeet black.

Similar Species

A. derbianus. Smaller and more variable in colouring with distinctive eye-mask; dorsal pelage mottled; tail black; widespread and common.

A. beecrofti. Smaller, dorsal pelage mottled; ventral pelage orange or yellow; tail relatively short (ca. 75% of HB), grey with small (or non-existent) pale-coloured brush.

Distribution Endemic to Africa. Rainforest BZ (Western Region). Recorded from E Liberia to Ghana west of the Volta R. In Liberia, apparently limited to the vicinity of the Cavally R., with only one record from further west in Deaple (Kuhn 1966). No records from Sierra Leone (Grubb *et al.* 1998).

Habitat Moist low-altitude rainforests with annual rainfall of 1400–3900 mm. Prefers primary forest with numerous tall emergents and palm trees.

Abundance Formerly regarded as quite common in rainforest but nocturnal habits and shyness make assessment of abundance very difficult. Sharing of hollows by up to six individuals suggests that local abundance and dispersion might be strongly influenced by availability of holes. Extensive logging of moist low-altitude rainforests implies a corresponding decline in overall abundance.

Adaptations Nocturnal and arboreal. During the daytime, Pel's Anomalures sleep in holes and hollow branches high in large trees. They emerge from their nests well after sunset and return long before daybreak (Adams 1894). One nest in a felled tree was contained in a large hollow some 5 feet deep and covered at the bottom with sticks and small branches. Cansdale (1946) took one of his specimens from

Anomalurus pelii

a hollow *Terminalia superba* tree. It is not known to what extent they make their own holes and hollows. There is some evidence that they modify their environment by pruning branches out of glide-paths (but not yet confirmed).

When disturbed in a hollow, Pel's Anomalures growl, hiss and snap their teeth (all noises that are amplified in a hollow). This behaviour may deter birds of prey, primates and small carnivores, as well as hornbills (which may compete for nest-hollows). Bold colouring,

Anomalurus pelii.

large size and aggressiveness may make this species less vulnerable to predation than the smaller species. Black and white colouring (with the exception of the melanistic subspecies *A. p. auzembergeri*) could also imply higher visibility and unambiguous postural signalling during intra-specific interactions. Strictly nocturnal activity probably diminishes the number of potential visual predator species, and apparently obviates the need for cryptic colouring. Forefeet primarily adapted for clinging on to bark and clasping branches; the absence of Digit 1 restricts handling of food, which is generally gnawed directly at source (although Adams [1894] noted that fruits are taken back to the nest and peeled).

At night, Pel's Anomalures glide from tree to tree, and are only visible when there is a full moon (Adams 1894). The surface area of the volplane (ventral surface of body and patagia) is ca. 2000 cm², larger than for other anomalures, probably because this species is substantially heavier than other species in the family.

Foraging and Food Little known. The diet is likely to be bark, probably from a few large tree species, fruits (especially oil palm *Elaeis guineensis* and other palm dates), leaves and flowers. Cansdale (1946) observed finely chewed leaves and 'mealy seed' in the stomach of one animal, and records that the droppings are green and oval. How the consumption of oil palm fruits by this species might differ from Beecroft's Anomalure remains undetermined.

Social and Reproductive Behaviour Adams (1894) never found more than three individuals sharing a hole, although he was informed that up to six may be found. Nothing is known about social interactions or home-range but contact calls have been described as deep hoots. Scent from well-developed inguinal glands suggests that olfactory communication is important.

Reproduction and Population Structure Cansdale (1946) recorded a ♂ with dilated testes in Aug, while a ♀ taken in Oct carried one embryo. Up to four young, more commonly 2–3, can be born at a time and two litters a year have been recorded. It seems

likely that competition for suitable resting and breeding holes is one of the primary determinants of reproductive and social life, but there is no corroborating data.

Predators, Parasites and Diseases There are currently no records of predation, although likely predators include large owls, hole-hunting hawks (such as African Harrier-hawks *Polyboroides typus* and Crowned Hawk-eagles *Stephanoaetus coronatus*), hornbills, snakes and palm civets. Nothing is known about parasites or diseases. They are, however, considered to be quite tasty and may be preyed upon by villagers in some localities.

Conservation IUCN Category: Data Deficient, previously assessed as Near Threatened.

Wholesale logging of the forests in the Upper Guinea rainforests has removed the larger part of the preferred habitat. The following National Parks are within the range of this species: Loffa-Mano, Cestos Sankwan and Sapo in Liberia; Taï and Azagny in Côte d'Ivoire; and Nini-Suhien and Bia in Ghana.

Jonathan Kingdon

Anomalurus pusillus LESSER ANOMALURE (DWARF SCALY-TAILED SQUIRREL)

Fr. Anomalure pygmée; Ger. Zwerg-Dornschwanzhörnchen

Anomalurus pusillus Thomas, 1887. Ann. Mag. Nat. Hist., ser. 5, 20: 440. 'Bellima and Tingasi, Monbuttu', DR Congo (= Niangara, DR Congo).

Taxonomy Synonyms: *batesi*. Subspecies: none. Chromosome number: not known.

Description Large dark speckled anomalure with black-tipped tail and without facial markings. Pelage long and soft. Dorsal pelage blackish to tan, speckled and agouti-like; hairs medium grey at base darkening towards tip; buff or pale brown at tip. Well-developed patagia, dark brown tending to yellowish on interfemoral patagia. Ventral pelage shorter than dorsal pelage, white or creamy-white or greyish-white. Cartilaginous spur projects outwards (within the membrane) from the elbow to margin of patagium. Head greyish without any markings. Muzzle rather slender. Vibrissae long, black. Ears slightly pigmented, naked. Limbs similar in colour to body. Hindlimbs with yellow bristle-like hairs covering claws. Tail relatively short (ca.

60% of HB), thin, hairs yellow at basal end turning to black-tipped at terminal end. Skull similar to *A. derbianus*. Nipples: not known, but presumably 2 + 0 = 4.

Geographic Variation In contrast to the other species in the genus, *A. pusillus* does not show any geographic variation (Schunke & Hutterer 2004).

Similar Species

A. derbianus. Larger; darker and heavier; black markings at base of ears; tail long, grey, with well-developed black brush at tip.

A. beecrofti. Larger; dorsal pelage grey, agouti; ventral pelage orange or yellow; tail long, thin, grey and with small blackish brush at tip.

*Anomalurus pusillus*

Distribution Endemic to Africa. Rainforest BZ (Western, West Central and East Central Regions). Recorded from isolated dispersed localities in Liberia, Cameroon, Equatorial Guinea (Rio Muni), Gabon and NE DR Congo. One record in Central African Republic. May also occur in W Uganda. Whether the Liberian specimens represent an isolated population or whether the species occurs elsewhere in West Africa is not known (Grubb *et al.* 1998); however, also recorded from Côte d'Ivoire (A. Schunke pers. comm.; not shown on map).

Habitat Equatorial rainforest. In Gabon and DR Congo, recorded only from rainforest, not from the outer margins or mosaics of the Congo Basin. Too few specimens have been collected to identify any preferences for forest type or structure. Mainly recorded at lower altitudes, but one specimen known from montane forest at 2200 m in E DR Congo (Rahm & Christiaensen 1963).

Abundance The rarest of the *Anomalurus* spp., and possibly very localized. After many years of collecting in E DR Congo, Rahm (1969b) listed data for only three specimens. In a 75 ha area in C Gabon, Julliot *et al.* (1998) estimated the density of Lesser Anomalures at about 5/km² (cf. 27–54/km² for *A. derbianus* and 164–437/km² for *Idiurus macrotis* in the same area).

Adaptations Arboreal and strictly nocturnal. In C Gabon (Julliot *et al.* 1998), nests were in hollows either near the base, or high up, in medium or large trees. The muscles of the jaws are relatively much less developed for chewing and gnawing than in *A. derbianus*, and therefore it is unlikely that branches are pruned to the same extent. Local variations in colour of the dorsal pelage in different populations may suggest that predators have exerted selection pressure for colour matching of the pelage with that of the trunks and branches.

Foraging and Food Little information. Rahm (1969b) recorded that the drupes of the Parasol tree *Musanga cecropioides* were eaten, and fruits of other trees suggested. A generalized resemblance of the teeth and jaws with those of Lord Derby's Anomalure suggests that Lesser Anomalures may also eat bark but possibly select softer, less fibrous barks, as are found on newer growth and some lianas. This implies that this species may find little food on large tree trunks and big boles.

Social and Reproductive Behaviour Lesser Anomalures seem to nest alone (Julliot *et al.* 1998), although Rahm (1960a) records one individual nesting with *A. jacksoni* (= *A. derbianus*).

Reproduction and Population Structure No information.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

GENUS *Idiurus* Pygmy Anomalures

Idiurus Matschie, 1894. Sber. Ges. Naturf. Freunde Berlin 8: 194. Type species: *Idiurus zenkeri* Matschie, 1894.

The genus *Idiurus* contains two species, which occur in the Rainforest BZ from Sierra Leone to W Uganda and W Tanzania. They occur only in the rainforest where there are large forest trees.

The genus is characterized by small size (HB less than 100 mm, GLS less than ca. 26 mm), flight patagia between the fore- and hindlimbs,

and small interfemoral patagia between the hindlimbs and the proximal end of the tail. The tail is long, thin and feathery, and there are small backwardly pointed scales on the undersurface of the tail. The outer margins of the flight patagium are fringed with fine hairs. A cartilaginous spur on the elbow provides support for the flight membrane. The

postorbital process of the frontal bone is absent and the infraorbital foramen is large, in contrast with that of squirrels. The nasal bone is comparatively deep in the dorsal–ventral plane, and the mandible is also deep in this plane giving the skull a rather ‘box-like’ shape. The lower process of each maxillary process extends anteriorly almost to the incisor (cf. *Anomalurus*). The posterior surface of each upper incisor has a well-defined notch (cf. *Anomalurus*), the premolar (P^4) is large and the last molar (M^3) is small (Figure 96).

Pygmy anomalures are arboreal and nocturnal. When resting in tree hollows during the day they are very gregarious, and often many tens of individuals will cluster together. In contrast, individuals are solitary when travelling and foraging at night. They are vegetarian, feeding on a variety of fruits and saps. Throughout the geographic range, abundance varies according to species and habitat, from rare to quite common; however, because of their small size, nocturnal activity and the density of preferred habitat, individuals are often difficult to observe. They are very efficient gliders (see *I. macrotis*), and when running along branches and tree trunks they use a running gait, rather than the bounding gait of *Anomalurus* spp.

Two species are recognized: *I. macrotis* and *I. zenkeri*. Some authorities recognize subspecies within *I. zenkeri* based on variation in pelage colouration. The two species are distinguished by size; their distribution is similar except that *I. zenkeri* does not occur in the Western Region of the Rainforest BZ. A multivariate study on 57 craniometric characters of the skulls of *Idiurus* supports the division into two species; however, although there is some geographic variation between populations of each species, these differences are not sufficient to warrant subspecific differentiation (Schunke & Hutterer 2007).

Figure 96. Skull and mandible of *Idiurus macrotis* (BMNH 3.2.4.16).

Richard W. Thorington, Jr

Idiurus macrotis LONG-EARED PYGMY ANOMALURE (LONG-EARED SCALY-TAILED FLYING SQUIRREL)

Fr. Anomalure nain à grandes oreilles; Ger. Großohr-Gleitbilch

Idiurus macrotis Miller, 1898. Proc. Biol. Soc. Washington 12: 73. Efulen, Cameroon.

Taxonomy Synonyms: *cansdalei*, *langi*, *panga*. Subspecies: none. Chromosome number: not known.

Description Very small anomalurid with feathery tail. Dorsal pelage sepia-grey to mouse-grey; hairs deep chocolate at base. Longer brown hairs interspersed throughout dorsal pelage. Ventral pelage

paler, sometimes slightly pinkish; hairs blackish-grey at base. Flight patagia and interfemoral patagia naked close to body, but covered with short dark hairs at edges. Ears relatively large and brown, mostly naked. Vibrissae black and extremely long. Forelimbs and hindlimbs short; wrist and ankles with sparse tuft of bristles; digits covered with fringe of hairs. Tail very long (ca. 150% of HB), thin, with long

delicate dark brown feather-like hairs on lateral sides. Ventral surface of tail with two rows of very short bristles and with small horny scales arranged in transverse rows of three or more near to basal end. Skull box-like in shape; maxillary process reaches well forward of the first premolar (almost to the incisor); incisor teeth with deep notch on posterior surface, M^3 small but more than half the size of M^1 or M^2 . Nipples: $2 + 0 = 4$.

Geographic Variation Individuals from Ghana are buffy-brown and paler than the darker brown individuals from elsewhere (Côte d'Ivoire and further west; Nigeria and further east).

Similar Species

I. zenkeri. Smaller in body and skull measurements; relatively smaller ears.

Anomalurus spp. Considerably larger; tail well covered with hairs, not 'feathery' as in *Idiurus* spp.

Distribution Endemic to Africa. Rainforest BZ (Western, West Central and East Central Regions). Distribution disjunct. Recorded from: (1) Sierra Leone to Ghana west of Volta R. (not recorded from Guinea but expected to occur there); (2) SE Nigeria, SW Cameroon, Equatorial Guinea (Rio Muni) and Gabon; and (3) NE DR Congo, WTanzania.

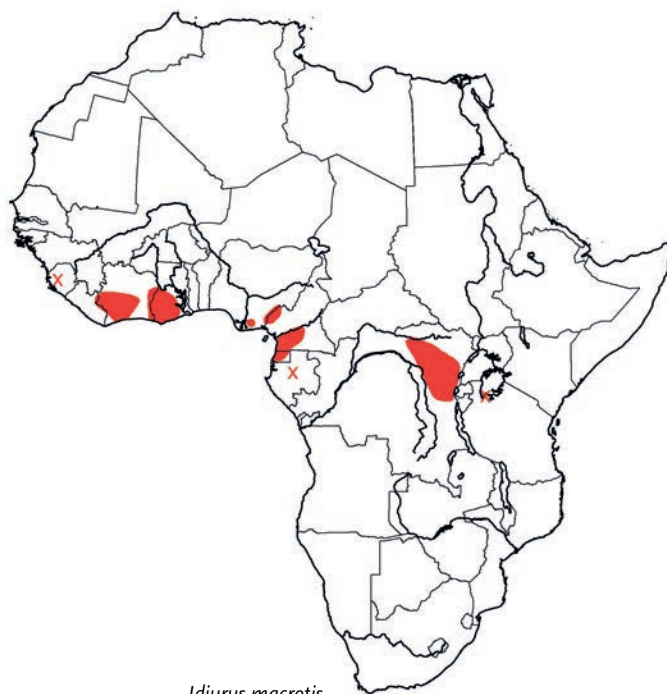

Habitat Rainforest where there are large trees with hollows and holes in the trunks.

Abundance Uncertain. In favoured habitats in Gabon, density is 164–437 ind/km² (Julliot *et al.* 1998).

Adaptations Arboreal and nocturnal. During the day, individuals rest in hollows and holes of many species of large forest trees. The preferred trees have hollows with entrances low down. Emergence from the hollow begins at 18:15 to 19:00h, and activity continues until 06:00h but without any clear pattern of activity during the night. There is some evidence of fidelity to a particular hollow, the same hollows being occupied by the same species (but not necessarily the same individuals) for many months or years (Julliot *et al.* 1998). Pygmy Anomalures (and Zenker's Anomalures) are very expert gliders.

Foraging and Food Vegetarian, mainly frugivorous. Gnaws and peels bark and probably feeds on sap (Julliot *et al.* 1998). In captivity, feeds only on palm nuts (Durrell 1952).

Social and Reproductive Behaviour Gregarious, but solitary at night. In Gabon, during the day, individuals rest in hollows, singly, in pairs, or in groups of up to 40 individuals (Julliot *et al.* 1998). When resting in groups, individuals huddle up to each other in a similar manner to communal bats. A particular hollow may contain only conspecifics, or may include other species such as *Anomalurus derbianus*, *A. beecrofti*, *A. pelii*, *Idiurus zenkeri* and *Graphiurus hueti* (now *G. nagtglasii*) or species of bats (*Hipposideros cyclops*, *Tadarida leonis*, *Tadarida* sp.) (Rahm 1966, Rosevear 1969, Jones 1971, Jeffrey

Idiurus macrotis

1975, Julliot *et al.* 1998). Home-range was about 3 ha for one ♂ radio-tracked during 48 hours; this ♂ travelled about 780 m per night (Julliot *et al.* 1998).

Reproduction and Population Structure In E DR Congo, embryo number: 1 ($n = 5$). Pregnancies recorded in Jun and Aug in E DR Congo (Rahm 1966); ♀♀ found with infants and young in Jun in Cameroon (Durrell 1952).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Conservation of rainforest with tall forest trees with hollows is essential for the survival of the species.

Idiurus zenkeri ZENKER'S PYGMY ANOMALURE (PYGMY SCALY-TAILED FLYING SQUIRREL)

Fr. Anomalure nain de Zenker; Ger. Zenkers Gleitbilch

Idiurus zenkeri Matschie, 1894. Sber. Ges. Naturf. Freunde Berlin 8: 197. Yaounde, Cameroon.

Taxonomy Synonyms: *haymani*, *kivuensis*. Subspecies: none recognized here. Chromosome number: not known.

Description The smallest of the anomalures, with a feathery tail. Pelage soft and dense, fine; ca. 8 mm on back. Dorsal pelage medium-brown; hairs dark grey at base, medium to pale brown at tip; grey colour of base often visible on surface. Ventral pelage similar to dorsal pelage. Well-developed flight patagia, supported anteriorly by calcaneum on forearm; small interfemoral patagia. Dorsally, pelage extends from back on to inner part of flight patagia, most of patagia covered by sparse short blackish hairs. Ventrally, also covered with sparse short blackish hairs, but ventral pelage does not extend on to inner part of flight patagia. Head similar in colour to dorsal pelage, without any contrasting markings. Long vibrissae (ca. up to 35 mm). Ears moderately large, rounded at tip, mostly naked. Forelimbs short, with feathering on outer surface of forefeet; four digits of equal length, each with small blackish claw. Hindfeet slightly elongated; five digits,

more or less equal in length. Tail very long (ca. 130% of HB), with two lines of short hairs (ca. 3 mm) placed laterally, interspersed with many long dark brown or black hairs (20–25 mm), which slant backwards at ca. 45 degrees to line of tail. Skull: maxillary process reaches well forward of the first premolar; incisor teeth with deep notch in posterior surface, M^3 small, and less than half the size of M^1 and M^2 . Nipples: not known.

Geographic Variation None recognized here (but see Genus profile).

Similar Species

I. macrotis. Larger (HB: 73–105 mm, T: 110–186 mm, WT: ca. 23–30 g); more widespread distribution.

Distribution Rainforest BZ (East Central and West Central Regions). Two separate ranges: (1) S Cameroon, Equatorial Guinea

Idiurus zenkeri.

(Rio Muni) and NW Gabon; (2) NE and E DR Congo, W Uganda. Also a few records from S Central African Republic.

Habitat Moist equatorial rainforest (Rahm 1966).

Abundance No information.

Remarks Less well known than *I. macrotis*, but probably similar in many respects. Gregarious. Rests in hollows and holes in trees with other species (see *I. macrotis*) during the day. In Cameroon, Sanderson (1940) recorded up to 100 individuals of this species and *I. macrotis* resting in the same tree. In Equatorial Guinea (Rio Muni), Jones (1971) found two *Anomalurus derbianus* and four *I. zenkeri* in the same hollow. Very agile, especially when running up the trunk of a tree (Kingdon 1974). The only information on reproduction is that none of the ♀♀ caught in May–Sep in E DR Congo was pregnant (Rahm 1966). A captive individual uttered mouse-like squeaks when captured (Kingdon 1974).

Conservation IUCN Category: Least Concern. Destruction of mature rainforest, especially the larger trees, which contain hollows for nesting, is a major threat to the species.

GENUS *Zenkerella* Cameroon Anomalure

Zenkerella Matschie, 1898. Sber. Ges. Naturf. Freunde Berlin 4: 23. Type species: *Zenkerella insignis* Matschie, 1898.

The genus *Zenkerella* is monotypic, and distributed in parts of the West Central Region of the Rainforest BZ. The genus is distinguished

from all other genera of anomalurids by a thick bushy black tail, and by the absence of any patagia (and therefore it is unable to glide as can all other species of the family). As in other anomalurids, there are pointed scales on the undersurface of the tail. The skull is similar in

Figure 97. Skull and mandible of *Zenkerella insignis* (MNHN 1970/112). The basicranial region of the skull is partially broken and displaced, and details of the ventral surface are obscured by dry tissue.

general form to that of *Idiurus* spp. although much larger and more box-shaped. The premaxilla is comparatively deep in the dorsal-ventral plane (as in *Idiurus*). The lower branch of each maxillary process extends anteriorly almost to the incisor teeth (as in *Idiurus*; cf. *Anomalurus*). The infraorbital foramen is relatively very large (as in *Idiurus*). The posterior surface of each upper incisor has a slight notch

(less so than in *Idiurus*; cf. *Anomalurus*), and upper M^1 and upper M^2 are larger than upper P^4 and upper M^3 , which are similar in size (Figure 97). Other characters are given in the species profile. The single species is *Zenkerella insignis*.

D. C. D. Happold

Zenkerella insignis CAMEROON ANOMALURE (CAMEROON SCALY-TAIL)

Fr. Zenkerelle; Ger. Kameruner Dornschwanzbilch

Zenkerella insignis Matschie, 1898. Sber. Ges. Naturf. Freunde Berlin 4: 24. 'Kamerun, Afr. Occ., Yaunde' (= Yaounde, Cameroon).

Taxonomy Synonyms: *glirinus*. Subspecies: none. Chromosome number: not known.

Description Medium-sized anomalure without patagia. Pelage soft and dense. Dorsal pelage slate or ashy-grey. Ventral pelage silver or grey, paler than dorsal pelage. Head ashy-grey; ears large, naked and rounded at tip. Long strong black vibrissae. Chin and chest ashy-grey. Limbs short, similar in colour to dorsal pelage, sometimes with ochre tinge on forelimbs. Forefeet with four digits. Hindfeet with five digits; tufts of stiff hairs on outer surface of ankles (function uncertain). Patagia absent. Tail long (ca. 85% of HB), with two rows of seven scales on undersurface close to base of tail; black hairs arranged distichously form a thick bushy tail, hairs shorter at base becoming progressively longer towards tip. Skull: see genus profile. Nipples: not known.

Zenkerella insignis.

Geographic Variation None recorded.

Similar Species

Idiurus spp. Patagia present; without black bushy tail.

Anomalurus spp. Patagia present.

Graphiurus spp. Patagia absent; no scales on undersurface of tail.

Funisciurus and *Heliosciurus* spp. Patagia absent; no scales on undersurface of tail.

Distribution Rainforest BZ (West Central Region, Gabon Subregion). Recorded from S Cameroon, Equatorial Guinea (Rio Muni and Bioko I.), Congo and Central African Republic. Not recorded from N Gabon, but likely to occur there. Kingdon (1997, map) records the species in E Nigeria (east of the Cross R.) but there is no evidence that the species has ever been recorded in Nigeria (Rosevear 1953, Happold 1987).

Habitat Rainforest, probably in canopy although may descend to ground level. Also recorded from semi-deciduous forest, close to savanna habitats (Pérez del Val *et al.* 1995).

Zenkerella insignis

Abundance The rarest of all the anomalures; known only from 11 specimens.

Remarks Arboreal and terrestrial (Pérez del Val *et al.* 1995). De Winton (1898) suggested that these anomalures may be diurnal (on the basis that, like squirrels, they do not have patagia); conversely Bates (1905) suggested that they are nocturnal, hiding in tree hollows during the day. Probably vegetarian.

Conservation IUCN Category: Least Concern; previously assessed as Data Deficient (2004) and Near Threatened (1996).

Family PEDETIDAE
SPRINGHARES

Pedetidae Gray, 1825. Ann. Philos., n. s., 10: 342.

| | | |
|---------------------|-------------|--------|
| Pedetes (2 species) | Springhares | p. 618 |
|---------------------|-------------|--------|

The family Pedetidae is endemic to Africa; it contains one genus and two species, one in East Africa and one in southern Africa. It is restricted to arid and semi-arid, relatively flat and open habitats with short grass, usually where there is little or no woody vegetation.

Characters of the family include large body size (HB: ca. 390 mm, WT: ca. 2.8 kg), long hindlimbs, long hindfeet (ca. 155 mm), short forelimbs, large eyes and long tail (ca. 425 mm). The lower trachea is unique among mammals in that it has a septum similar to that present in some birds (Nowak 1999). The skull is robust, dorsally flattened in lateral view with large expanded nasal bones, the lower maxillary process (of the zygomatic plate) extends anteriorly towards the cutting edge of the upper incisor teeth, orbits are large, tympanic bullae are well developed (especially the occipital part, visible in dorsal view), as is the pterygoid process (see photos in De Graaff 1981). Dental formula: $I^{1/1}, C^{0/0}, P^{1/1}, M^{3/3} = 20$. Upper incisor teeth opisthodont. Cheekteeth hypsodont, continuously growing, flattened, with a single re-entrant fold on the lingual side of each cheektooth. Mandible robust, coronoid process much reduced, and short angular process; strong ridge for muscle attachment on angular process. The species of Pedetidae are among the largest of the Rodentia (similar in size to species of Hystricidae and Thryonomidae), and are the only large saltatorial rodents in Africa. Size categories of species in the family (based on mean head and body length) are given in the order Rodentia profile.

The earliest known fossils (*Parapedetes namaquensis* from Namibia and *Megapedetes pentadactylus* from Kenya) are from the early Miocene (20 mya) (Montgelard *et al.* 2001). *Megapedetes* is larger than *Pedetes*, but otherwise already morphologically very similar (MacInnes 1957). Two extinct species of *Pedetes* are known from the fossil record; *P. gracilis* and *P. hagenstadi*, both from South Africa. The oldest fossil of *P. capensis* comes from the Pleistocene of Zimbabwe (De Graaff 1981). The pre-Miocene fossil history and origin of Pedetidae is not known, but it is likely that Pedetidae emerged in the early Tertiary (Bugge 1974a), either in Africa or Asia (Montgelard *et al.* 2001).

The affinities of pedetids are among the most obscure of all rodents and, therefore, subject to much debate and enquiry (Luckett

& Hartenberger 1985, Carleton & Musser 2005). There is some agreement that pedetids represent a very early, independent, lineage within Rodentia. In recognition of this, Ellerman (1940) erected the superfamily Pedetoidea within the suborder Sciuromorpha. Simpson (1945) also placed pedetids in Sciuromorpha, but in the superfamily Anomaluroidea. More recently, Bugge (1974a, b) erected the suborder Anomaluromorpha (to include both Pedetidae and Anomaluridae), and Landry (1999) erected the suborder Pedetomorpha (to include only Pedetidae).

The subordinal position is uncertain as pedetids share both hystricognath and sciurognath morphological characters (Jaeger 1988a, Huchon *et al.* 2000, Dieterlen 2005b). Recent molecular findings, however, strongly support inclusion of Pedetidae within Sciurognathi (Matthee & Robinson 1997a). This position is further supported by studies of foetal membranes and reproductive features (Luckett 1985, Otianga'a-Owiti *et al.* 1992). The emerging view is that the hystricognath characters of pedetids are due to parallelisms and, therefore, are not useful for phylogenetic inference (Luckett & Hartenberger 1985, Matthee & Robinson 1997a).

The familial relationships of pedetids are also uncertain. The two most critical questions are whether pedetids and anomalurids comprise a natural clade, and if so, where does this sister-group fit cladistically among the other major rodent associations (Carleton & Musser 2005). Although the microstructure of incisor enamel (Martin 1995, Huchon *et al.* 2000) and some palaeontological data (Jaeger 1988a, Landry 1999) do not support a close relationship between Pedetidae and Anomaluridae, some anatomical features (e.g. middle-ear structure [Lavocat & Parent 1985] carotid arterial pattern [Bugge 1974a, b, 1985]) and molecular data (Montgelard *et al.* 2001) strongly support the relationship between these two families (Montgelard *et al.* 2001) and, therefore, recognition of the suborder Anomaluromorpha (Bugge 1974a, b). Here Pedetidae and Anomaluridae are placed together in the suborder Anomaluromorpha (following Dieterlen 2005b; see also Carleton & Musser 2005).

Thomas M. Butynski

GENUS *Pedetes*
Springhares

Pedetes Illiger, 1811. Prodr. Syst. Mamm. Avium., p. 81.

The genus contains two species widely distributed in eastern and southern Africa. Characters of the genus are given in the family profile. Until recently, the genus was considered to be monotypic (e.g. Dieterlen 1993b), but recent research shows that the populations in East Africa are distinct and allopatric from those in southern Africa.

Based on phenotypic and morphological characters, *P. capensis* has been considered by some authorities to represent the only species in the genus (Allen & Loveridge 1927, Ellerman *et al.* 1953, Kingdon

1974, 1997, Misonne 1974, De Graaff 1981, Meester *et al.* 1986, Skinner & Smithers 1990, Dieterlen 1993b). In contrast, on the basis of skull characters and molecular data (see family profile), the East African Springhare is sufficiently distinct to warrant recognition as a separate species *Pedetes surdaster* (Thomas 1902b, Hollister 1918, 1919, Allen 1939, Coe 1967, Davies 1982, Dieterlen 2005b). The two species also differ in physiological characters (basal metabolic rate, thermal conductance and thermal neutral zone) and chromosome

number (see species profiles). While the morphology of skulls of *Pedetes* from the northern part of the range (S Kenya) and from the southern part of the range (Cape of Good Hope) differ considerably (Thomas 1902b, Hollister 1918), many of these differences are not apparent when intermediate populations are examined. For example, skulls from Tabora (W–C Tanzania; Allen & Loveridge 1927) and Dodoma (C Tanzania; Miller 1927) resemble more closely those of *P. capensis* from the Cape of Good Hope (>3000 km to south) than *P. surdaster* from L. Naivasha, Athi Plains and Sotik regions of Kenya (ca. 600 km to north), even though the East Africa and southern Africa populations are (apparently) separated by ca. 350 km.

The species are distinguished by size and shape of bones of the skull (especially the nasals, bullae and premaxillary processes), size and shape of the teeth, and shape of the braincase.

Thomas M. Butynski

Pedetes capensis SOUTHERN AFRICAN SPRINGHARE

Fr. Lièvre Sautteur du Sud; Ger. Südafrikanischer Springhase

Pedestes surdaster.

Pedetes capensis (Forster, 1778). K. Svenska Vet.-Akad. Handl. Stockholm (1) 39: 109. Cape of Good Hope, Western Cape Province, South Africa.

Taxonomy Originally described in the genus *Yerbua*. The taxonomy of this species is much debated. Here, following Dieterlen 2005b (see also family profile), *P. capensis* is the southern representative of the genus (see also *P. surdaster*). Synonyms: *albaniensis*, *angolae*, *cafer*, *damarensis*, *fouriei*, *orangiae*, *salinae*, *typicus*. Subspecies: none recognized here. Chromosome number: $2n = 38$ (Matthee & Robinson 1997b).

Description The only large, saltatorial-bipedal rodent in southern Africa. Pelage straight, long and soft. Dorsal pelage sandy to cinnamon-buff with scattered, long black-tipped guard hairs (ca. 35 mm) that decrease in density towards tail. Underfur of dorsal pelage thick, 25–33 mm long; hairs grey on basal half, glossy-brown on distal half. Ventral pelage white, yellowish, pale buff or pale orange; hairs 20–30 mm long, fine and sparse. Colour of pelage varies geographically (see below). Head broad, short and blunt. Face and lower half of ears sandy, yellowish-brown, cinnamon-buff, or rufous-brown. Vibrissae and eyelashes black. Nose, cheeks, forehead and crown cinnamon overlain with varying amounts of brownish-black. Ears long (70–80 mm); lower half yellowish-brown, upper half brownish-black. Inner surface of limbs, as for ventral pelage. Forelimbs short with five digits, each with long curved, sharp claws (ca. 19 mm); plantar pad near base of Digit 1 large, rounded and naked; plantar pad at base of Digit 5 smaller and oval. Hindlimbs very long and robust, with four digits (Digit 1 absent); Digit 3 elongated; each digit with large, triangular, hoof-like nail (see photographs in De Graaff 1981). Pelage on undersurface of hindfeet cream or pale grey. Tail long (ca. 110% of HB) and bushy, similar in colour to dorsal pelage with brownish-black to jet black on terminal 25–37% and black patch on underside at base; hairs 50–60 mm long, coarser and duller than on body, lacking grey on basal half. Skull stoutly constructed, thick; breadth of premaxillary processes (on side of nasal bones) ca. 3 mm (cf. ca. 1 mm in *P. surdaster*); auditory bullae large (ca. 19 mm long; cf. ca. 13 mm in *P. surdaster*), extending posteriorly behind the foramen magnum (Thomas 1902b) (Figure 98). Infant

and juvenile pelage softer and paler, underfur of dorsal pelage cream rather than grey, and pelage at base of tail and on undersurface of hindfeet blackish. Faecal pellets distinctive: rectangular but irregular with raised point at one end (ca. $8 \times 8 \times 15$ mm to ca. $10 \times 10 \times 21$ mm). Nipples: $2 + 0 = 4$ (not $1 + 0 = 2$ as given in Skinner & Smithers 1990); anterior pair just below axilla.

Figure 98. Skull and mandible of *Pedetes capensis* (RMCA 305).

Geographic Variation Nine subspecies have been described, but their validity is uncertain (Misonne 1974, Meester *et al.* 1986, Skinner & Smithers 1990, Matthee & Robinson 1997b, Dieterlen 2005b). There appears to be a slight north–south decline in body size from N Botswana (Smithers 1971) through SE Botswana (Butynski 1979a) to S South Africa (Lynch 1983, Anderson 1996) (see Measurements). A very dark, almost melanistic, individual (black pelage over most of body; ventral pelage whitish cream; hairs with silvery-brown tip) is in the collection of the AMNH.

Similar Species

P. surdaster. External morphology similar; breadth of premaxillary processes ca. 1 mm; length of bullae ca. 13 mm; reflective eye shine at night from only one eye at same time (as in *P. capensis*); chromosome number $2n = 40$; East Africa only.

Galago moholi. Much smaller (total length ca. 375 mm; body weight ca. 170 g); arboreal but may hop bipedally on ground; reflective eye shine at night from both eyes at same time; sympatric.

Distribution Endemic to Africa. Zambezan Woodland, South-West Arid (Kalahari Desert, Namib Desert and Karoo subzones), Highveld, South-West Cape and Coastal Forest Mosaic BZs. Present in Angola, Namibia, South Africa, SDR Congo, SW Zambia, Botswana, W and S Zimbabwe and S Mozambique (De Graaff 1981, Skinner & Smithers 1990). No records for Swaziland and Lesotho. Distribution highly fragmented due to lack of suitable habitat over much of geographic range. Range limits are from 08° S to 34° S and from 13° E to 35° E. Altitudinal range: ca. 10–2000 m (Lynch 1983, Kofron 1987, G. Kerley pers. comm.), with mean annual rainfall ca. 200–800 mm, either falling during one or two wet seasons per year (Smithers 1971, Butynski 1979b, Lynch 1983).

Habitat Arid and semi-arid, relatively flat and open areas with short grass, with little or no woody vegetation, and where the soil

is sandy, deep and compact, and suitable for digging burrows. Also found on agricultural lands. Generally absent from areas of tall grass, dense woodland and from mopane (*Colophospermum mopane* dominant) and miombo (*Brachystegia* spp. dominant) scrub and woodland where the soils are clay and poorly drained. Highest densities of *P. capensis* are attained on and near flood-plains of rivers, lakes and swamps, and on fossil lake beds (pans) where the vegetation is open, the grass is short and green, rhizomes and corms are present all year, and sandy soils are available. Such preferred habitats have some of the most succulent, protein-rich, mineral-rich grasses in southern Africa and, therefore, also receive more or less continuous heavy grazing from other herbivores, both wild and domestic. The flat, open terrain of these habitats is ideal for bipedal locomotion, for detection and avoidance of predators, and may also facilitate social behaviours such as finding mates (Smithers 1971, Butynski & Mattingly 1979, Skinner & Smithers 1990, Anderson 1996, Peinke & Brown 2006).

Abundance Common and widespread over much of southern Africa. In seven habitat types near Kimberley, South Africa, densities range from 3/km² in 'Kalahari thorn/sandveld' to 19/km² in 'panveld' (Anderson 1996). At 15 sites in Eastern Cape Province, South Africa, densities range from 1/km² to 99/km² (Peinke & Brown 2006). Other known densities include ca. 40/km² in Sandveld Nature Reserve, South Africa (Watson 1992), ca. 100/km² in S. A. Lombard Nature Reserve, South Africa, and ca. 370/km² on pan-associated habitats in S. A. Lombard Nature Reserve (Van der Walt 1989).

Adaptations Nocturnal and terrestrial. *Pedetes capensis* combines morphological features for living in an open, nocturnal, terrestrial environment (where a high level of mobility is required) with morphological features for excavation of burrows and life underground. External features associated with terrestrial activities include elongated and powerful hindlegs, long tail and large ears and eyes. Features associated with subterranean life include strong, long claws on forefeet for digging, valvular nostrils that can be closed, and ears with well-developed antitragus capable of folding back and lengthwise along the mid-line preventing entry of soil. The long whiskers, long sensory hairs on dorsal pelage, long eyelashes and patch of long sensory bristles just above the eye probably assist in orientation in the burrow (Skinner & Smithers 1990). Sharp, chisel-like teeth are capable of cutting through roots and other soft objects during excavation.

Although *P. capensis* hops bipedally when moving to and from foraging sites, it moves on all four legs when foraging, putting the weight on the short forelegs and then moving the hindlegs forward in a hare-like manner. When eating, weight is placed on the hindfeet, perineum and tail, leaving the forefeet free to manipulate food. To avoid predators, *P. capensis* makes bipedal 'ricochet' leaps of up to 2 m in length as it moves towards its burrow. Although the forefeet are well-adapted for digging, they are also dexterous, allowing for the extraction of plant parts from both above and below ground, and for manipulation of the food so that the most nutritious portions can be selected (e.g. green seeds and subterranean storage organs). When sleeping, the body is bent forward until the forelimbs are between the thighs, and the top of head is resting on the ground between the feet.

Vision, hearing and sense of smell are acute. The large eyes allow running and avoidance of objects on moonless nights, and the frequent movement of the ears and regular sniffing of the air are

Pedetes capensis

vital to intra-specific communication and social interactions with conspecifics, as well as the detection of predators – both above and below ground. Underground predators include snakes and mongooses (Butynski & Mattingly 1979, Anderson 1996).

Although primarily nocturnal, there are a few records of activity during daylight hours (Shortridge 1934, Anderson 1996). Generally, Southern African Springhares do not emerge from the burrow until ca. 30 minutes after sunset, and do not return to the burrow later than 30 minutes before sunrise. In Kalahari Desert, most activity above ground is during middle of night (i.e. 4–8 hours after sunset; Butynski 1984). Near Kimberley, numbers above ground increase up to ca. 24:00h and then decline steadily until ca. one hour before sunrise (Anderson 1996). In Eastern Cape Province, activity is fairly constant through the night with a decline starting two hours before sunrise (Brown & Peinke 2007).

The number of *P. capensis* on Kalahari pans declines as air temperature declines, with few above ground at temperatures below +1 °C. They remain active during light rains but move into burrows when rains are moderate to heavy (Butynski 1984). Near Kimberley, low air temperatures also affect foraging activity. In winter, they forage closer to their burrows (<120 m) than in summer (150–400 m). As in Botswana, *P. capensis* remain active during light rain, but move into burrows when rain is moderate to heavy. *Pedetes capensis* tend to stay close to their burrows under windy conditions (Anderson 1996). In Eastern Cape Province, temperature and wind do not seem to affect activity, although very strong wind does reduce activity (Brown & Peinke 2007). These behaviours probably help conserve energy and avoid thermoregulatory stress.

In the Kalahari Desert, activity on pans is greatly influenced by moonlight. The distance of individuals away from the burrows and onto the pans is inversely correlated with intensity of moonlight. When there is no moonlight, mean distance onto pans is ca. 58 m, but only 4 m when there is a full moon. Intensity of moonlight, however, does not affect the numbers of individuals on pans (Butynski 1984). Similarly, near Kimberley, they feed up to 400 m from burrows when there is no moonlight and seldom >40 m from burrows when the moon is full (Anderson 1996). In Eastern Cape Province, they are less active on full moon nights than on new moon nights, and activity begins to decrease earlier on full moon nights. As the moon rises in the sky, and as shadows produced by trees and shrubs become reduced in size, individuals move closer to trees and shrubs to remain within shadows. This 'shadow-seeking' behaviour is probably an adaptation for predator avoidance (Butynski 1984).

Limiting above-ground activity until dark (when air temperature is lowest and humidity highest), and selectively feeding on moist plant parts, are behavioural adaptations that considerably reduce water loss. Physiologically, Southern African Springhares are fairly well adapted to an arid environment. They do not drink water even when available; meeting moisture requirements from rain and dew on vegetation, and from food as preformed and metabolic water (Butynski & Mattingly 1979, Anderson 1996, Peinke & Brown 1999). They are able to survive seven days of water deprivation and tolerate a 30% loss of body weight – twice the level that is fatal in most other mammals. The ability to be highly selective, and to feed on rhizomes, tubers and leaf bases, ensures a plentiful and relatively stable food (and water) supply throughout the year (during most years), even in a highly seasonal environment.

Peinke & Brown (2003) found that *P. capensis* (unlike *P. surdaster*; Müller *et al.* 1979) has a higher than expected basal metabolic rate and a lower than expected minimum thermal conductance. This, together with a relatively low, lower critical temperature and broad thermal neutral zone, indicates physiological adaptations suitable for the low (below freezing) night-time temperatures that occur during the southern African winter. Like other desert-adapted species, *P. capensis* is a good osmoregulator and is similar to some true desert species in its ability to tolerate dehydration and maintain blood plasma volume. It also produces relatively dry faeces but, surprisingly, does not produce highly concentrated urine (Peinke & Brown 1999).

Burrows provide a relatively stable, moderate temperature and humidity in which to live and raise young, and some protection against predators. Burrows are typically 70–122 cm deep, 36–46 m long, and have up to nine entrance holes (Butynski & Mattingly 1979). Burrows lack food, nesting materials and chambers. The porous soil in which burrows are excavated provides good insulation and a micro-environment of relatively moderate, stable temperature, and air saturated with water vapour. In the Eastern Cape Province, mean monthly temperature at more than 1.5 m inside of one burrow located in open grassland ranged from 12 to 22 °C through the year. In this region, mean monthly maximum air temperatures outside are +19 °C to +27 °C, and mean minimum air temperatures are +5 °C to +16 °C; absolute air temperatures range from –5 °C to +45 °C (Peinke & Brown 2003, 2006).

Southern African Springhares often exert a large influence on the vegetation structure and plant diversity around burrows and on feeding sites through exposure of fresh soil, preferential utilization of plant species and deposition of plant material and dung. The effect of digging up rhizomes, corms and tubers is that patches of soil are often totally worked-over and temporarily denuded of vegetation. These denuded patches are often >3 m in diameter (Peinke & Brown 2006), but can be in excess of 240 m² (Anderson 1996, T. Butynski pers. obs.). This disturbance encourages growth of several species of grass that are a preferred food, and which make up the bulk of the diet. These and other effects of burrow excavation and feeding are documented in detail for sites in Botswana (Butynski & Mattingly 1979) and South Africa (Anderson 1996, Peinke & Brown 2006).

They are generally silent, but occasionally give 'grunts' and soft 'growls'. 'Screams' (also termed 'squeals' or 'bleats') are emitted when distressed or frightened, such as when captured by a predator, and 'grunts' and 'growls' are given when annoyed or uncomfortable. 'Sighs' are given but their function is not known (Anderson 1996, T. Butynski pers. obs.).

Many of the specialized morphological, physiological and behavioural features of *P. capensis* are best explained as adaptations to a semi-arid, open environment, and for avoidance of predators. Nutritious, short grasses occur during the dry months on relatively moist and fertile flood-plains and pans. As a medium-sized, bipedal mammal, *P. capensis* is small enough to be a selective forager, yet mobile enough to avoid predators and to travel several hundred metres from the burrow to the foraging sites. The major 'trade-off' is that a medium-sized herbivore attracts a large array of predators, both small and large.

Foraging and Food Herbivorous, feeding primarily on grasses. The burrow represents the 'core area' for foraging activities, with

foraging routes emanating out from the burrow. Individuals on the Kalahari pans are frequently 25–250 m, and occasionally as far as 400 m, from their burrows (Smithers 1971, Butynski 1984). Near Kimberley, the core area is within ca. 40 m of the burrows, and maximum distance is ca. 400 m (Anderson 1996).

Southern African Springhares are highly selective feeders, feeding on the most nutritious parts of plants. Diet in the Kalahari Desert is comprised almost entirely of grass parts – roots, corms, green stems, green leaves and green seeds (Butynski 1984). Here, green seeds of grasses, especially of *Urochloa* spp., comprise much of the diet during the wet season (Butynski & Mattingly 1997). Small invertebrates are ingested incidentally (Butynski 1982a). Lumps of soil frequently found in stomachs (T. Butynski pers. obs.).

Near Kimberley, Anderson (1996) found that the diet comprises at least 20 species of plants (eight grasses, five dwarf shrubs, one geophyte, five trees and shrubs, one herb). Together, *Cynodon dactylon* (41%), *Schmidtia pappophoroides* (17%), *Eragrostis lehmanniana* (8%) and *Gladiolus permealibis* (8%) comprise ca. 74% of the diet. Plant parts eaten include rhizomes, stolons, green culms and green leaves, but, unlike in the Kalahari Desert, not seeds. In Eastern Cape Province, the diet is predominantly rhizomes of *C. dactylon*, tubers of yellow nut sedge *Cyperus esculentus* and leaf bases of *Eragrostis curvula* (Peinke & Brown 2006). At all sites, the diet includes the roots, stems and leaves of shrubs and small trees, but these items are a minor part of the diet (Butynski 1982b, 1984, Anderson 1996, Peinke & Brown 2006).

Underground storage organs are extracted from the ground with claws of forefeet and nipped off with the teeth. Green grass seeds are readily removed from the stem by pulling, with one hand, the stem through diastema between incisors and premolars. Where abundant, rhizomes of *C. dactylon* are the most important food. *Pedetes capensis* often reach high densities when *C. dactylon* is abundant (Smithers 1971, Anderson 1996, Peinke & Brown 2006, T. Butynski pers. obs.).

Data on sex and age differences in the quantity and quality of foods eaten by *P. capensis*, on seasonal changes in their physical condition, and on seasonal changes in food availability and quality, are presented in Butynski (1979b, 1982a, b) and Anderson (1996).

Social and Reproductive Behaviour Solitary and polygamous. Individuals are solitary when in the burrow except when a mother has her single young (Butynski & Mattingly 1979, Anderson 1996); on one occasion, an adult ♂ shared a burrow with an adult ♀ but remained 2–3 m apart (Peinke & Brown 2005). Above ground, they may form temporary groups (when densities are suitably high). In Botswana, 36% of individuals on pans and 35% off pans occur in groups ($n = 2545$). Group size ranges from two to six and increases with time after sunset. Of the 2545 individuals encountered, 62% were alone, 25% were in pairs and 9% were in groups of three. Of five age/sex categories considered, only adult ♂♂ are represented in groups more than expected by chance. Forming groups probably facilitates predator detection and avoidance, as well as foraging, learning and reproduction (Butynski 1984).

Mating is preceded by prolonged chasing of the ♀, usually by two adult ♂♂, for up to 45 minutes. Copulation lasts 3–5 seconds and is usually undertaken by fastest ♂ (Anderson 1996).

Intra-specific aggression, defence of sites, or other acts typical of territorial species have not been observed. Southern African Springhares have widely overlapping home-ranges and often join feeding groups

without any overt aggression (Anderson 1996, Peinke & Brown 2005, T. Butynski pers. obs.). In Eastern Cape Province, 70% of burrows were, over the course of one year, used by a single animal, suggesting that burrows are ‘defended’ against conspecifics. Scent marks from the perineal glands, and urine (which is frequently deposited at the burrow entrance), may indicate to conspecifics that the burrow is occupied; under these conditions, occupancy by another individual will seldom occur until the scent marks of the previous inhabitant are more than one month old. Changing burrows frequently, and the non-occupancy of a burrow, may help to reduce the numbers of potential predators attracted by the odour of a frequently used burrow, and to reduce the number of parasites and parasite eggs that accumulate in the burrows (Peinke & Brown 2005).

Near Kimberley, minimum home-range size over periods of 2–6 months varied from 0.3 to 2.8 ha (mean 1.4 ha, $n = 4$) (Anderson 1996). In Eastern Cape, the minimum area covered by the burrows used by seven *P. capensis* radio-tracked for 1–12 months ranged from 0.4 to 28.5 ha (mean 10.6 ha) (Peinke & Brown 2005). Distances separating burrows and preferred feeding sites, and the size and quality of burrowing and feeding sites, play a major role in determining the size and shape of the home-range (Butynski 1984, Anderson 1996, D. Peinke pers. comm.).

There is no evidence that ♂♂ assist in raising young.

Reproduction and Population Structure Monotocous with aseasonal reproduction in most localities. Southern African Springhares breed throughout the year in Botswana (Butynski 1979b, Butynski & Hanks 1979) and in Eastern Cape Province, South Africa (Peinke & Bernard 2005), and show slight seasonality at Kimberley (Anderson 1996). In all locations, more-or-less continuous reproduction occurs despite living in strongly seasonal, sometimes severe, environments where there are distinct wet/hot and dry/cold seasons and considerable variations both in daylength and food supply. However, during prolonged droughts when there is extreme shortage of food, reproductive activity is greatly restricted or ceases completely (Kofron 1987).

Median length of gestation is assumed to be the same as for *P. surdaster*, i.e. 78 days (range: 72–82 days, $n = 3$ in captivity) (Rosenthal & Meritt 1973, Velte 1978; see also Kofron 1987). Litter-size: one. Only three cases of twinning have been recorded (0.8%, $n = 380$ pregnancies; Shortridge 1934, Van der Horst 1935, Butynski 1979b, Lynch 1983, Anderson 1996, Peinke & Bernard 2005, R. H. N. Smithers pers. comm.). Of 404 fetuses, 200 recorded in the right uterine horn and 204 in left uterine horn (Smithers 1971, Butynski 1979b, van der Merwe *et al.* 1980, Kofron 1987, Gewers 1993, Anderson 1996, Peinke & Bernard 2005).

Mean birth-weight is assumed to be the same as for *P. surdaster* (i.e. 273 g, range 238–319 g, $n = 7$ in captivity; Hediger 1950, Coe 1967, Rosenthal & Meritt 1973, Velte 1978). At birth, young covered with dense hair, except on throat, ventrum, genitalia, insides of legs and soles of feet, which are nearly naked (Butynski 1982b). Full covering of hair at ca. Week 3 (F. F. Velte pers. comm.). Precocious; able to move, dig and face-wash within a few hours of birth. Bipedal hopping Day 4. Ears erect within few days of birth. Eyes may be open at birth, but sometimes not fully open until Day 14 (Butynski 1980, Peinke & Bernard 2005). First emergence from burrow and weaning occurs at ca. Week 7 (Botswana; Butynski 1979b, 1982b) or ca. Week

5 (Kimberley; Anderson 1996). Newborns weigh ca. 10% as much as mothers, with ears and hindfeet 56% adult length. Predicted weight of 'newborn litter' for a mammal the weight of adult ♀ (ca. 3.0 kg) is 426 g, or 14% the mother's weight. Although the weight of the newborn *P. capensis* is large (ca. 300 g), it is ca. 30% less than expected in relation to the weight of the mother (Butynski 1980).

Sexual maturity in ♂♂ attained when 2.3 kg (Botswana; n = 286; Butynski & Hanks 1979), 2.5 kg (Kimberley; n = 126; Anderson 1996) and 2.8 kg (Eastern Cape Province; n = 59; Peinke & Bernard 2005). Some ♂♂ spermatogenically active at ca. eight months but most not until ca. 12 months (Kofron 1987, Anderson 1996). Adult males produce active sperm throughout year. Females reach sexual maturity and conceive for first time when 2.7–3.0 kg (Butynski 1979b, Anderson 1996, Peinke & Bernard 2005). Youngest pregnant ♀♀ are 13 months old, but some do not conceive until 24 months (Anderson 1996). Sexual maturity is attained at a much older age compared to other rodents of similar size (Peinke & Bernard 2005).

Females are polyoestrous with pregnancies separated by non-pregnant period. Reproductive parameters vary according to locality. In Botswana, adult ♀♀ have a mean non-pregnant period of ca. 24 days, a mean interval between conceptions of ca. 101 days, and a mean of ca. 3.6 pregnancies/year (Butynski 1979b). Near Kimberley, adult ♀♀ have a mean non-pregnant period of ca. 39 days, a mean interval between conceptions of ca. 116 days, and a mean of ca. 3.1 pregnancies/year (Anderson 1996); in Eastern Cape Province, the figures are 49 days, 126 days and 2.9 pregnancies/year, respectively (Peinke & Bernard 2005). The reproductive rate is unusually low for a rodent, even for a rather large one. Mean length of lactation in Botswana is ca. 50 days, with some ♀♀ lactating for >60 days. Lactation ceases when young are ca. 1.3 kg, ca. seven weeks of age and beginning to forage above ground. Lactation lasts for longer than predicted for a mammal of this size (Eisenberg 1981). In Botswana, no ♀ with a foetus heavier than 59 g was lactating (n = 34) (Butynski 1979b). Likewise, in Eastern Cape Province, no ♀ with a foetus heavier than 54 g was lactating (n = 10) (Peinke & Bernard 2005). Near Kimberley, only two of 16 ♀♀ (12%) with a foetus heavier than 100 g were lactating (Anderson 1996). A foetus reaches 59 g and 100 g at ca. 57 days and ca. 62 days post-conception, respectively (Butynski 1980). Hence most pregnant ♀♀ stop lactating before the final trimester of pregnancy, but a few lactate during at least 80% of the pregnancy.

Male:female ratio at parity (60 : 61) among foetal *P. capensis* large enough for sex determination (Butynski 1979b, Anderson 1996). Male:female ratios at parity for juveniles + adults in all three of the better-studied populations (Botswana, 321 : 312 [Smithers 1971, Butynski 1979b]; near Kimberley, 187 : 180 [Anderson 1996]; Eastern Cape, 59 : 61 [Peinke & Bernard 2005]). However, in SE Zimbabwe, Kofron (1987) obtained 51 ♂♂ and 72 ♀♀ during the third year of a three-year drought.

Some juvenile:adult ratios are as follows: 1 : 2.6 (Botswana; Butynski 1979b), 1 : 3.0 (Kimberley; Anderson 1996), 1 : 3.6 (Eastern Cape Province; Peinke & Bernard 2005) and 1 : 2.4 (SE Zimbabwe; Kofron 1987). No longevity data available for *P. capensis* (maximum longevity for *P. surdaster* in captivity is 14 years [Jones 1982]). Peinke & Bernard (2005) suggest that the life-span of *P. capensis* in the wild is typically 6–12 years, but T. Butynski (pers. obs.) believes that the mean life-span in the wild is much shorter than this and is probably closer to 2–3 years.

Predators, Parasites and Diseases At least 23 known or potential species of predators prey on *Pedetes capensis* in the Kalahari Desert (Butynski & Mattingly 1979), and Anderson (1996) lists 31 predators in the Kimberley area. In a combined sample of 602 stomachs of Black-backed Jackals *Canis mesomelas* from Botswana, Zimbabwe (Skinner & Smithers 1990) and South Africa (Bothma 1966, Anderson 1996), 48 (8%) contained remains of *P. capensis*. Anderson (1996) observed 11 attempts by Black-backed Jackals to catch *P. capensis*; only two (18%) were successful. Given their size, abundance and sympatric distribution over most or all of their geographic range, the Black-backed Jackal, Cape Fox *Vulpes chama* and Caracal *Felis caracal* are likely to be the most important mammalian predators. In the Kalahari Gemsbok N. P., South Africa/Botswana, *P. capensis* constitute a large part of the diet of Cheetahs *Acinonyx jubatus* (W. Labuscagne pers. comm. in Smithers 1971). Similarly, Skinner & Smithers (1990) record that Southern African Springhares form a major part of the diet of Cheetahs in the drier areas of Botswana.

Many ectoparasites have been recorded. Mites: *Radfordiella capensis*, *Radfordiella meridionalis*, *Androlaelaps marshalli* and *Histioglyphus santos-diasi*. Lice: *Eulinognathus denticulatus*. Pulicid fleas: *Echidnophaga bradyi*, *Echidnophaga gallinacea*, *Ctenocephalides conatus*, *Ctenocephalides felis*, *Synosternus caffer*, *Parodontis riggenbachii* and *Xenopsylla cryptonella*. Ticks: *Amblyomma hebraeum*, *Haemaphysalis leachii*, *Hyalomma marginatum*, *Rhipicephalus appendiculatus*, *Rhipicephalus sanguineus*, *Rhipicephalus simus*, *Rhipicephalus tricuspis* and *Rhipicephalus capensis*. Endoparasites include the following nematodes: *Dermatophys veligara*, *Hyracofilaria hyracis*, *Oesophagostomum susannae*, *Physaloptera capensis* and *Trichuris pedetei* (De Graaff 1981, Butynski 1982a, Anderson 1996, Anderson & Kok 2003). There is no evidence to suggest that parasites or diseases play a significant role in the regulation of population numbers (Butynski 1982a). Because of their parasites, *P. capensis* may play a role in the transmission to man and domestic stock of bubonic plague, rickettsiosis, babesiosis, theileriosis and toxicosis paralysis (De Graaff 1981).

Conservation IUCN Category: Least Concern.

Although widespread and even abundant at many localities, populations of *P. capensis* are in rapid decline over much of their geographic range (Lynch 1983). While most of the decline is related to habitat degradation as a result of overgrazing by domestic stock, and to habitat loss as a result of conversion of natural habitats to agriculture, over-hunting is also partly responsible for the decline in some areas (Butynski 1973, Lynch 1983, C. Anderson pers. comm.).

Pedetes capensis are a major source of bushmeat and an important pest of crops (Smithers 1971, De Graaff 1981, Anderson 1996). In Botswana, they are probably the most important wild animal in the diet of local humans. A single band of bushmen may kill more than 200 annually. It is estimated that the people of Botswana kill 2.5 million individuals each year. This represents ca. 2.2 million kg of meat each year, the equivalent of 20,000 cattle (Butynski 1973). Bushmen make the skin into garments, use the long sinew of the tail as thread and smoke dried faecal pellets. Butynski (1973) estimated that 10–15% of maize, sorghum, beans and groundnuts grown in Botswana are destroyed by *P. capensis*. Elsewhere they sometimes cause extensive damage to wheat, oats, maize and other crops (Shortridge 1934).

Pedetes capensis is one of Africa's most biologically unique and economically important mammals. In addition, it is likely to be a

keystone species in some ecosystems. As such, the long-term survival of this species needs to be ensured. As one of Africa's most studied, widespread, locally abundant and easily located and observed mammals, there is considerable opportunity for additional research. Applied research might focus on obtaining more information on the economic importance of this species, and on what the sustainable harvest is under various natural and man-made conditions. Interesting theoretical questions involve behaviour and how it is affected by environmental conditions and population density. Comparative ecological, behavioural and physiological studies with *P. surdaster* (which lives near the Equator in a much less seasonal environment) would be particularly enlightening.

Measurements

Pedetes capensis

HB (♂ ♂): 402 (?–?) mm, n = 12
 HB (♀ ♀): 401 (?–?) mm, n = 14
 T (♂ ♂): 448 (417–485) mm, n = 12
 T (♀ ♀): 429 (410–443) mm, n = 12
 HF (♂ ♂): 161 (150–170) mm, n = 14
 HF (♀ ♀): 161 (153–182) mm, n = 14
 E (♂ ♂): 75 (70–80), n = 14
 E (♀ ♀): 75 (69–79), n = 14
 WT (♂ ♂): 3.26 (?–?) kg, n = 13
 WT (♀ ♀): 3.26 (?–?) kg, n = 13
 GLS: 88.6 (84.9–91.9) mm, n = 14*
 GWS: 54.3 (50.3–60.4) mm, n = 14*
 P⁴–M³: 16 (14.2–17.8) mm, n = 14*

Pedetes surdaster EAST AFRICAN SPRINGHARE

Fr. Lièvre Sautteur de l'Est; Ger. Ostafrikanischer Springhare

Pedetes surdaster Thomas, 1902. Ann. Mag. Nat. Hist., ser. 7, 9: 440. Mordat, Naivasha Prov., mile 365 of Uganda Railway, Kenya. 2000 m.

Taxonomy See *Pedetes capensis* profile. Based on phenotypic and morphological differences, it is debatable whether *surdaster* should be designated as a full species or as a subspecies of *P. capensis* (Dieterlen 1993b, 2005a). Standard body measurements for *surdaster* fall within the range for six populations of *capensis* (Hollister 1919, see *P. capensis* profile). Thomas (1902b), Hollister (1919), Miller (1927) and Davies (1982) note that, relative to *P. capensis*, *P. surdaster* has smaller nasal bones and smaller auditory bullae, narrower premaxillary processes, a less deeply concave anterior palate, narrower and shallower incisors and molars, and a more vaulted braincase. Thomas (1902b), Hollister (1918, 1919), Ellerman (1940), Coe (1969), De Graaff (1981), Davies (1982) and Dieterlen (2005a) treat *surdaster* as a full species. Recent molecular data also support this position (Matthee & Robinson 1997b). Among the molecular differences is a difference in chromosome number. Some significant physiological differences also exist (Müller *et al.* 1979, Peinke & Brown 2003). Synonyms: *currax*, *dentatus*, *larvalis*, *taborae*. Subspecies: none recognized here (but see Geographic Variation). Chromosome number: 2n = 40 (Matthee & Robinson 1997b).

Description The only large, saltatorial bipedal rodent in East Africa (morphologically similar to *P. capensis* of southern Africa; see *P. capensis*). Pelage straight, long and soft. Dorsal pelage sandy, yellowish-brown, or cinnamon-buff. Guard hairs sparse, black. Underfur of dorsal pelage grey over proximal half and glossy brown over distal half. Ventral pelage off-white to light yellow, without underfur. Head relatively large. Eyes large. Ears long, narrow, upright. Forelimbs very short with five digits, each with long, curved, sharp claw. Hindlimbs very long and robust, with four digits (Digit 1 absent). Tail long (ca. 106% of HB) and bushy. Infants and juveniles similar in colour to adults. Skull stoutly constructed, thick. Skull: breadth of premaxillary process (on side of nasal bones) ca. 1 mm (cf. ca. 3 mm in *P. capensis*); auditory bullae large (ca. 13 mm long; cf. 19 mm in *P. capensis*) not extending posteriorly behind foramen magnum (Thomas 1902b). Sexes alike in colour and body size (♂ ♂ may, on average, be slightly larger). Males may have linear body measurements 3–5% longer than ♀ ♀, but sample size small. Faecal pellets distinctive (see *P. capensis*). Nipples: 2 + 0 = 4.

Pedetes surdaster.

Geographic Variation Five subspecies have been described but there is no consensus about how many of these, if any, should be recognized (Misonne 1974, Meester *et al.* 1986, Skinner & Smithers 1990, Matthee & Robinson 1997b, Dieterlen 2005b). Assessing validity of the named subspecies is hampered by lack of knowledge of the geographic limits of each, as well as by the apparent absence of major barriers to gene flow; close examination might reveal that such barriers are provided by large areas of hard-packed ground (e.g. lava flows, black cotton soil) or unsuitable vegetation (e.g. forest). Differences may be clinal rather than absolute. No subspecies are recognized here.

Similar Species

P. capensis. External colouration and morphology similar; breadth of premaxillary processes ca. 3 mm; length of auditory bullae ca. 19 mm; reflective eye shine at night from only one eye at same time (as *P. capensis*); chromosome number: $2n = 38$; southern Africa only.

Galago senegalensis and *Otolemur garnettii*. Much smaller (<300 g and <1200 g, respectively); usually arboreal but sometimes hop bipedally on the ground; reflective eye shine at night from both eyes at same time; sympatric.

Distribution Endemic to Africa. Sudan Savanna, Somalia–Masai Bushland, Coastal Forest Mosaic and Zambezian Woodland BZs. Recorded from SC Kenya and Tanzania. Reports from C Kenya (Laikipia, Samburu and Meru Districts) and coastal Kenya need verification. No confirmed records north of Nakuru, Gilgil or Thika in SC Kenya, or south of L. Rukwa in SW Tanzania. Distribution sometimes extremely patchy as suitable habitats often widely scattered.

Habitat Semi-arid, relatively open and flat areas with short, nutrient-rich grasses, with little or no woody cover, and where soils are well-drained, compact, deep and sandy, and suitable for digging burrows. Also on agricultural lands where suitable burrowing sites are present. Preferred habitats often present along the margins of rivers and lakes, in alluvial valleys, sandy plateaux, near human dwellings, gardens, bomas and boreholes. These sites are also highly

attractive to many other herbivores, tend to be heavily grazed and are relatively nutrient-rich due to the heavy deposit of manure and urine (Kingdon 1974, Stelfox 1986, Augustine *et al.* 1995, T. Butynski pers. obs.). Generally absent from areas of tall grass, dense bush, dense woodland and forest, and from most miombo (*Brachystegia* spp. dominant) woodlands where the soils are lateritic ('hard-pan') and poorly drained. However, may occur within miombo woodlands where sandy soils are present (e.g. along river courses). The broad features of the habitats of *P. surdaster* are similar to those of *P. capensis* in southern Africa (Smithers 1971, Butynski & Mattingly 1979, Butynski 1984, Anderson 1996, Peinke & Brown, 2006). Altitudinal range ca. 100–2000 m (Thomas 1902b, Kasigwa & Howell 1975, T. Butynski & Y. de Jong pers. obs.), but mostly above 1000 m. Mean annual rainfall ca. 400–1200 mm, but mostly 600–1100 mm.

On the Athi-Kapiti Plains, Kenya, *P. surdaster* prefers areas near sources of perennial water that are subject to heavy grazing, both by

Pedetes surdaster

native ungulate species (primarily Wildebeest *Connochaetes taurinus* and Thomson's Gazelles *Eudorcas thomsonii*) and by cattle. Star (or couch) grass *Cynodon dactylon* covers ca. 67% of the ground in such areas (Augustine *et al.* 1995). Stelfox (1986) found that the high input of nitrogen and phosphorus from ungulate faeces around cattle bomas and boreholes leads to dramatically higher levels of crude protein and lower fibre levels in the vegetation in comparison to more distant sites. *Cynodon dactylon* is able to out-compete other grass species in these highly disturbed but fertile sites.

Abundance Few data available. On Athi-Kapiti Plains numbers seen during surveys ranged from 1/km² in *Themeda-Balanites/Acacia drepanolobium* short woodland to 24/km² in *Cynodon-Balanites* grassland (n = 361 animals; Augustine *et al.* 1995). Absent from very large areas within geographic range and, where present, density often <1/km² (T. Butynski & Y. de Jong pers. obs.).

Adaptations Nocturnal and terrestrial. Many of the adaptations of *P. capensis* probably also apply to *P. surdaster* (see *P. capensis* profile). Kingdon (1974) discusses the several peculiar anatomical adaptations related to bipedal hopping and how this mode of locomotion has benefits for moving over flat, open ground, but is ill-adapted to circumventing obstacles, as is required when running over broken ground, or ground with anything more than short, sparse vegetation.

Augustine *et al.* (1995) did not find any difference in the number of animals seen between 22:00 and 24:00h and between 01:00 and 03:00h. There are only four records for daylight hours: one at daybreak (06:30h) (O'Brien 1982), one at 10:20–11:30h (Kasigwa & Howell 1975), one on a 'dark day' (Hollister 1919) and the fourth in 'broad daylight' (S. Thomsett pers. comm.).

Individuals probably always construct their own burrows. Burrows are generally less than 1 m deep. The entrances are often temporarily sealed with sand from the inside. Each burrow system usually harbours but one animal; at most two adults and one young (Kingdon 1974). When sleeping, *P. surdaster* assumes the same pose as for *P. capensis* (see above); contact of the top of the head with the ground may allow detection of vibrations through the ground that are created by movements of conspecifics and predators (Kingdon 1974, as *P. capensis*).

Pedetes surdaster are generally quiet, but emit 'bleats' and 'grunts' (Kingdon 1974, as *P. capensis*). Infants give 'squeaks' and high-pitched 'bleats' (Coe 1967).

Compared to *P. capensis* (Peinke & Brown 2003), *P. surdaster* has a low basal metabolic rate and high rate of thermal conductance (n = 2; Müller *et al.* 1979). This combination reduces the endogenous heat load and facilitates heat loss – adaptations typical of mammals that are seldom, if ever, exposed to low temperatures (e.g. tropical mammals and mammals that spend all or part of their time underground).

Where abundant, East African Springhares have a large influence on vegetation structure and plant diversity around their burrows and on feeding sites. This influence is a result of the exposure of fresh soil, preferential utilization of plant species, and deposition of plant material and dung. Individuals often totally dig over extensive areas as they forage for plant parts, mixing dung and seeds into the soil (T. Butynski pers. obs.).

Many of the specialized morphological, physiological and behavioural features of *P. surdaster* are best explained as adaptations to a semi-arid, open environment, and avoidance of predators. Nutritious,

short grasses occur during the dry months on comparatively moist and fertile (often seasonally flooded) flood-plains, lake shores and valley bottoms. Smaller mammals could harvest these grasses, but they would be extremely susceptible to predators as these habitats lack vegetative cover and the soils are often too hard and/or too wet for burrowing. As a medium-sized, bipedal mammal, *P. surdaster* is small enough to be a selective forager, yet mobile enough to avoid predators and to travel several hundred metres from the burrow to the foraging sites. The major 'trade-off' here is that a medium-sized herbivore attracts a large array of predators, both small and large.

Foraging and Food Herbivorous. Probably very similar to *P. capensis*. Feeds primarily, and selectively, on grass parts: roots, rhizomes, corms, stems, leaves and seeds, and crops such as sweet potatoes, groundnuts, pumpkins, maize and wheat. Prefers green grasses high in protein and water, especially *C. dactylon*. Reported to eat locusts and beetles (Kingdon 1974, Augustine *et al.* 1995). One record of feeding (at day break) on the flesh and bone of a Cape Hare *Lepus capensis* killed by a vehicle the previous day (O'Brien 1982).

Social and Reproductive Behaviour Solitary and polygamous. Probably similar to *P. capensis*. No territorial behaviour reported. Of 361 individuals encountered during transects on the Athi-Kapiti Plains, 59% were alone and 41% were in groups of two to six, with one group of 11. Of 104 sighted from viewing towers, 58% were alone and 42% were in groups of two or three (Augustine *et al.* 1995). These results are similar to those for *P. capensis* in Botswana (Butynski 1984).

Reproduction and Population Structure Little-studied. Probably similar to *P. capensis*. Pregnant ♀♀ were collected in Mar, Apr, Aug, Sep, Oct and Nov (no sample sizes given) suggesting that females breed throughout the year (Coe 1969). Females collected in Mar contained very small embryos (8 and 15 mm) as well as full-term foetuses. Estimated median length of gestation in captivity is 78 days (range: 72–82 days, n = 3) (Rosenthal & Meritt 1973, Velte 1978). Monotocous (n = 27 births); no records of twinning but few observations. Mean birth-weight of seven young born in captivity: 273 g (range 238–319 g) (Hediger 1950, Coe 1967, Rosenthal & Meritt 1973, Velte 1978). The 238 g neonate survived to >4 months of age (Velte 1978), indicating that it was probably not born prematurely. Total length at birth of three young born in captivity was 343, 368 and 375 mm (Jones 1941, Rosenthal & Meritt 1973). Detailed information on the anatomy of the reproductive tract is given by Coe (1969).

Young are born in a burrow in an unlined chamber (Kingdon 1974). After parturition, the mother cleans the neonate, chews the umbilical cord off near the point of attachment to the neonate and eats the placenta. At birth, head, back, tail and outer surface of limbs are well-covered with pale fawn-brown pelage (ca. 5 mm long on back) but chin, throat, ventral surface and insides of limbs have only a sparse covering of hair. At birth, eyes partly open, ears open and almost erect. Neonates are able to move about and to wash face, ears and top of head. Urination and defecation accomplished spontaneously. Like adults, infants sleep with the body bent forward between the legs with the top of head on the ground (Jones 1941, Hediger 1950, Coe 1967, Rosenthal & Meritt 1973, Velte 1978). Captive-born young

attained the following weights: 250 g at birth, 530 g at Day 21 (Hediger 1950); 238 g at birth, 410 g at Day 19; 272 g at birth, 370 g at Day 20 (Velte 1978). The smallest animal collected ($n = >22$) above ground by Coe (1969) was 1473 g, indicating that young do not leave the burrow until they achieve a weight close to this. There is no evidence that food is carried into the burrow and so young presumably suck until they depart the burrow and begin to feed above ground (as for *P. capensis*). Maximum longevity in captivity is 14 years (Jones 1982).

Predators, Parasites and Diseases No information. Likely to have many of the same predators as for *P. capensis*; many of the species of predators present in the range of *P. capensis* also occur over the range of *P. surdaster*. Black-backed Jackals *Canis mesomelas* and Caracals *Felis caracal* are likely to be the main predators of *P. surdaster*, as they appear to be for *P. capensis*.

Conservation IUCN Category: Least Concern.

Unlikely to be threatened as a species. Fairly widespread and locally common, but populations have been reduced or extirpated from some localities due to habitat degradation, habitat loss and/or over-hunting. *Pedetes surdaster* is a source of bushmeat and a pest of crops, but how important it is to the people of East Africa is not known.

The two species of *Pedetes* are among Africa's most biologically unique mammals. In addition, they are likely to be keystone species in those ecosystems where they are most abundant. As such, the long-term survival of these two species needs to be ensured. Where extirpation appears likely, conservation actions should be taken to remove the threats. While *P. capensis* is one of Africa's most studied smaller mammals, *P. surdaster* remains comparatively poorly known. Both are very similar phenotypically and morphologically, but each lives under very different climatic and biotic conditions. For example, most of the plant species differ between the ranges of the two species,

and *P. surdaster* probably never experiences temperatures lower than +5 °C, whereas *P. capensis* frequently forages when temperatures are below 0 °C, and sometimes as low as -8 °C. Applied research might focus on assessing the economic importance of this species, and on what the sustainable harvest is under various natural and man-made conditions.

Measurements

Pedetes surdaster

HB (♂ ♂): 393 (336–457) mm, $n = 27$

HB (♀ ♀): 387 (350–440) mm, $n = 26$

T (♂ ♂): 418 (390–484) mm, $n = 30$

T (♀ ♀): 418 (390–451) mm, $n = 26$

HF (♂ ♂): 156 (140–161) mm, $n = 30$

HF (♀ ♀): 148 (130–159) mm, $n = 27$

E (♂ ♂): 77 (67–89) mm, $n = 12$

E (♀ ♀): 73 (65–85) mm, $n = 13$

WT (♂ ♂): 2.7 (?–?) kg, $n = 10$

WT (♀ ♀): 2.8 (?–?) kg, $n = 12$

GLS (♂ ♂): 85 (80–88) mm, $n = 3$

GLS (♀ ♀): 87 (86–88) mm, $n = 4$

GWS (♂ ♂): 55 (52–57) mm, $n = 13$

GWS (♀ ♀): 54 (52–57) mm, $n = 15$

P⁴–M³ (♂ ♂): 15 (13–16) mm, $n = 13$

P⁴–M³ (♀ ♀): 16 (15–17) mm, $n = 14$

Kenya (mostly Naivasha and Machakos) and Tanzania (AMNH, BMNH, CUMV, FMNH, NMK, USNM, Hollister 1918, 1919, Miller 1927, Allen & Loveridge 1927, Coe 1969, S. Thomsett pers. comm.)

Family CTENODACTYLIDAE

GUNDIS AND PECTINATOR

Ctenodactylidae Gervais, 1853. Ann. Sci. Nat. (Paris), ser. 3, 20: 245.

| | | |
|----------------------------------|--------------------|--------|
| <i>Ctenodactylus</i> (2 species) | Gundis | p. 629 |
| <i>Felovia</i> (1 species) | Felou Gundi | p. 634 |
| <i>Massoutiera</i> (1 species) | Mzab Gundi | p. 636 |
| <i>Pectinator</i> (1 species) | Speke's Pectinator | p. 638 |

The family is endemic to Africa, and contains four genera and five species (Table 44) widely distributed in arid and semi-arid habitats north of the Equator. Typically, all species (commonly known as 'gundis') are associated with rocky habitats. 'Gundi' is the name given by Berbers to *Ctenodactylus* spp. and this name is applied indiscriminately now to all the living species of the family.

Members of the family are very similar in external appearance. The head and body is of medium size (typically HB: 160–193 mm), thickset, with short limbs and a very small brushy tail. Pelage is very dense (173–289 hairs/cm²; George 1978a). The fore- and hindlimbs are short with four digits on each foot. The family name, Ctenodactylidae, is derived from the comb-like bristles surmounting the digits of the hindfeet (George 1978a). The claws are sharp and usually do not touch the ground; they are used exclusively for climbing and are not for excavating or for grooming. Skull: broad posteriorly due to wide flaring zygomatic arches, large auditory bullae and large orbits. Auditory bullae weakly to moderately inflated, size varying in relation to the aridity of the habitat, but not as well developed as in gerbils (Gerbillinae) and jerboas (Dipodidae). Dental formula: $I^{1/1}, C^{0/0}, P^{1-2/1-2}, M^{3/3} = 20$ or 24 ; P^4 smaller than molars. Zygomatic arches wide and thick, maxillary process of zygomatic arch well developed, zygomatic plate small extending dorsally only to mid-way on maxillary process. Each upper incisor with single faint groove (absent in some specimens of *Massoutiera mzabi*). Cheekteeth rootless except in *Pectinator spekei* (Jaeger 1971). Mandible thin with almost no development of coronoid process, condylar process in line with cheekteeth; angular process short in *Felovia* and *Pectinator*, but pointed and well-developed in *Ctenodactylus* and *Massoutiera*. Size categories of species in the family (based on mean head and body length) are given in the order Rodentia profile.

Gundis are not able to dig burrows although they may push small stones with their forefeet or nose in order to improve the entrances of their shelters. Gundis are restricted to rocky habitats that provide shelters (George 1974). They are able to ascend almost perpendicular rock faces by pressing the body against the rock face and using their claws to cling to the slightest irregularities of the rock. The flat broad head with ears that can be flattened, and a compressible thorax, enable gundis to edge into narrow crevices in order to escape danger. Inside a crevice, a gundi can work its way up or down or sideways (George 1974). Female gundis have two pairs of nipples, one pectoral and one thoracic. Gestation is long for a small mammal (50–70 days), and the young are born fully furred, with their eyes open (George 1978b). Gundis make species-specific calls that are readily identifiable (George 1981a).

Gundis are mainly, if not completely, diurnal (George 1974, Gouat, P. 1991a) and have behavioural adaptations for temperature regulation. They change their resting position according to the ambient temperature, and stay in the shade during the hottest part of the day. The temperature threshold initiating behavioural responses varies between species according to the aridity of the habitat (Gouat 1991a). Nevertheless, these behavioural adaptations are not sufficient to explain how gundis cope with their water balance. Renal function and concentrating ability are unspecialized, at least in *Ctenodactylus vali* and *Massoutiera mzabi* – the two species that live in the central Sahara (de Rouffignac *et al.* 1981, George 1988). Gundis are herbivorous and do not drink free water. Efficient water absorption may occur in the long large intestine (which may be as long as 100 cm in *C. gundi* and hence five times as long as the head and body length); faecal pellets are very dry (Gouat 1993). Detailed physiological studies are required.

The family Ctenodactylidae is the only recent family of the infraorder Ctenodactylomorpha of the suborder Hystricomorpha (Dieterlen 2005c). This taxon (previously referred to as the superfamily Ctenodactyloidea) includes some of the oldest of rodent fossils (Dawson *et al.* 1984). It is characterized by a combination of an hystricomorphous

Table 44. Species in the family Ctenodactylidae. Arranged in alphabetical order.

| Species | HB mean (range) (mm) | T mean (range) (mm) [% of HF] | Groove on each upper incisor | Auditory bulla | Shape of forehead | Length of faecal pellets mean (range) (mm) | Notes |
|----------------------------|----------------------|-------------------------------|------------------------------|---------------------|-------------------------|--|--------------------------------------|
| <i>Ctenodactylus gundi</i> | 193 (150–228) | 31 (20–45) [81%] | Present | Moderately inflated | Large and straight | 11.0 (9.8–11.9) | E Morocco to W Libya |
| <i>Ctenodactylus vali</i> | 160 (124–185) | 36 (27–43) [102%] | Present | Greatly inflated | Narrow; slightly hooked | 7.9 (7.3–8.2) | Morocco, Algeria, Libya |
| <i>Felovia vae</i> | 179 (169–190) | 73 (67–80) [221%] | Present | Slightly inflated | Large and straight | 10.6 (10.0–10.9) | Mali, Mauritania |
| <i>Massoutiera mzabi</i> | 176 (125–210) | 52 (33–85) [148%] | Absent (or slight groove) | Greatly inflated | Large and straight | 7.3 (6.6–7.9) | Algeria, Mali, Niger, Chad |
| <i>Pectinator spekei</i> | 170 (155–190) | 74 (60–80) [224%] | Absent | Moderately inflated | Large and straight | n. d. | Ethiopia, Eritrea and Horn of Africa |

skull with a sciurognathous jaw, and a non-molariform P⁴ (Jaeger 1971). From these observations, and others, Hartenberger (1985) concluded that ctenodactylids may be the stem group of all other rodents. More recent studies, based on molecular analysis, proved the relatedness between Ctenodactylidae and hystricognathous rodents (Beintema *et al.* 1991). Huchon *et al.* (2000) confirmed that Ctenodactylidae and Hystricognathi robustly cluster together, and proposed the formation of a new clade named Ctenohystrica. This clade, together with other lineages (Sciuroidea and Gliridea), is thought to have emerged close to the Cretaceous–Tertiary boundary (Huchon *et al.* 2000). Following their emergence and radiation in Asia during the Eocene, Ctenodactyloidea extended its range to the west and disappeared from the Far East (Dawson *et al.* 1984). The Ctenodactylidae reached the Mediterranean region and northern Africa during the late Eocene (Dawson *et al.* 1984). Two genera, *Africanomys* and *Metasayimys*, are described from the late Miocene from North Africa. During the early Pleistocene, *Irhoudia* was common in

North Africa (Jaeger 1971). Nowadays, the Ctenodactylidae is reduced to four living genera and five species. See Rosevear (1969) for further discussion.

The five species can be classified into three groups according to their phylogenetic affinities and distribution (George 1974, 1979b, 1985a). Speke's Gundi *Pectinator spekei* is the most primitive species (Jaeger 1971) and occurs only in the Horn of Africa. North of the Sahara Desert are the two species of *Ctenodactylus*. The two other species, *Felovia vae* and *Massoutiera mzabi*, are closely related and are typically sub-Saharan species (George 1979b, 1985a), although *M. mzabi* also occurs further north to the northern edge of the Sahara (Gouat *et al.* 1984, Gouat 1988a, 1991a).

The genera may be distinguished by tail length and visibility, alarm calls, size of auditory bullae, size of faecal pellets and geographic distribution.

Patrick Gouat

GENUS *Ctenodactylus* Gundis

Ctenodactylus Gray, 1830. *Spicilegia Zoologica* 2: 10. Type species: *Ctenodactylus massonii* Gray, 1830 (= *Mus gundi* Rothmann, 1776).

Ctenodactylus gundi.

The genus contains two species that live in rocky habitats of the northern Sahara Desert BZ from Morocco to Libya. The first-named species was described as *Mus gundi* by Rothman in 1776. In 1830, Gray proposed the current definitive name *Ctenodactylus* (derived from Greek *ctenos*, comb; and *dactylos*, toe). Characters of the genus include: palate extends posteriorly to the cheekteeth, toothrows converge anteriorly, upper molar teeth simple without infoldings on both sides (Figure 99), and tail shorter or about equal in length (ca. 80–102%) to the hindfoot (Misonne 1974). The two species are difficult to differentiate in the field. The species can be distinguished by body size, shape of the forehead, distance between the auditory bullae, type of alarm call and the mean length of the faecal pellets.

Patrick Gouat

Ctenodactylus gundi ATLAS GUNDI (COMMON GUNDI)

Fr. Goundi de l'Atlas; Ger. Atlas-Gundi

Ctenodactylus gundi (Rothman, 1776). In: A.L. Schölzer (ed.), Briefwechsel, Book 6, Part 1, Göttingen: 339. Gharian, 80 km S of Tripoli, Libya.

Taxonomy Originally described in the genus *Mus*. Synonyms: *arabicus*, *massonii*, *typicus*. Subspecies: none. Chromosome number: $2n = 40$ (George 1979b).

Description General appearance of a small guinea-pig with a short hairy tail and small ears. Pelage very dense and soft. Dorsal pelage buffy-brown, dull grey underfur. Ventral pelage buff to yellowish-grey. Head flat and broad. Forehead large and straight. Muzzle short with long black vibrissae. Nostrils naked and black. Eyes large and round surmounted by long vibrissae. Ears flattened on the head, oval, black inside bordered by a dense fringe of short stiff whitish-grey hairs. Fore- and hindlimbs short; four digits on each foot. Digits of the hindfeet surmounted by comb-like bristles. Claws sharp; do not reach the ground in the normal position. Tail relatively short (ca. 81% of HF), usually hidden by pelage of rump and not visible. Skull: see family and genus profiles; each upper incisor with single groove, angular process of mandible elongated posteriorly forming the most posterior part of the mandible (as in *Massoutiera*, cf. *Felovia*, *Pectinator*), auditory bullae moderately inflated (ca. 15.4 mm, 51% of GLS), distance between bullae ca. 10 mm) (Figure 99). Emits whistle alarm call when disturbed. Mean length of faecal pellets: 11.0 (9.8–11.9) mm. Nipples: $2 + 0 = 4$. In lactating ♀♀, nipples appear as black dots on the buff pelage.

Geographic Variation None recorded.

Similar Species

C. vali. On average smaller; forehead narrow and slightly hooked; auditory bullae inflated to a greater extent; chirp alarm call; mean length of faecal pellet <9 mm; partially parapatric.

Massoutiera mzabi. On average smaller; tail relatively longer; present in northern Sahara; allopatric.

Distribution Endemic to Africa. Mediterranean Coastal BZ and northern fringe of Sahara Arid BZ in NW Africa. Recorded from E Morocco to W Libya. In E Morocco: High Atlas east of wadi Dades, and upper Moulouya basin in the Middle Atlas (Petter & Saint-Girons 1965, Aulagnier & Thévenot 1986, P. Gouat pers. obs.). Algeria: Saharan Atlas from Ksour Mts in the west to Nemencha Mts in the east (Gouat & Gouat 1984, Gouat 1988b). Tunisia: High Tell south of a line Enfida–Kasserine, Matmata Mts, Dahar Hamada, and slopes bordering the Djefara depression (Séguignes 1979, 1983, Séguignes & Vernet 1996). Western Libya: Tripolitanian Mts (Nefusa, Tigrina and Jefren Mts) (Ranck 1968).

Habitat Semi-desert mountainous rocky habitats that contain natural shelters. Large rocks ($>2 \text{ m}^3$) are necessary for main shelters (Gouat & Gouat 1983). Natural caves and human constructions (retaining walls along roads, piles of stones along fields, small rocky dams) may also be used as shelters. Atlas Gundis avoid forests and dense vegetation cover (e.g. esparto grass *Stipa tenacissima* steppe),

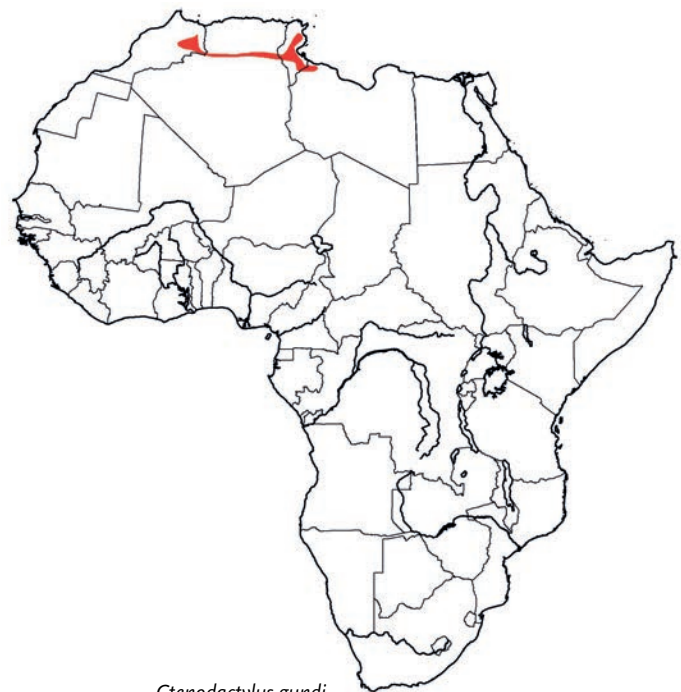

preferring sites with sparse vegetation, where the average annual rainfall is 100–400 mm (Gouat & Gouat 1983, Séguignes 1983). Dispersing animals may be found in isolated small rocky massifs up to 10 km away from normal preferred habitat (Gouat 1988a, Séguignes & Vernet 1998).

Abundance Common in suitable habitats when food resources are abundant: e.g. 20–25 animals/km² (evaluated from data in Séguignes 1979). Rare in desert habitats (Séguignes & Vernet 1996). One year without rain may cause the disappearance of gundis from previously suitable habitat (Gouat & Gouat 1982).

Adaptations Similar to *C. vali* (see Species profile).

Foraging and Food Herbivorous. Atlas Gundis are selective feeders. The species of plants eaten vary greatly from place to place. For example, in a semi-desert site of the Aures Mts (E Algeria), the diet consisted of *Anabasis articulata*, *Artemisia herba-alba*, *Asparagus acutifolius*, *Astragalus armatus*, *Haloxylon articulata*, *Lycium afrum*, *Rhus tripartitus* and grass. In a high elevation site, 10 km away, the diet was *Euphorbia buplroides*, *Lamium* sp., *Rhamnus alaternus*, *Rhamnus lycioides* and grass (P. Gouat & J. Gouat 1987). In both sites, the diet comprised only ca. 30% of the plant species present. These gundis are capable of climbing small trees or bushes in order to eat the leaves.

Social and Reproduction Behaviour Gundis live in small colonies (up to 11 adults) with typically one adult ♂ and several adult ♀♀ with young and juveniles (Séguignes 1979, Gouat 1988a).

*Ctenodactylus gundi*

The social group is stable and long lasting; one adult reproductive ♂, for example, was observed in the same colony in the Aures Mts for more than three years (Gouat 1988a). Members of the colony occupy a common home-range, which remains stable throughout the year, and from one year to the next. The size of home-ranges depends on food abundance, stability of resources and on local social constraints. In the Aures Mts, the home-range of three colonies was 1031 m² and 5468 m² in semi-desert habitats, and 685 m² in a high elevation habitat (Gouat 1991b). The whole of the home-range is equivalent to a territory. It is actively marked and defended against conspecific intruders (Gouat 1991a). Animals deposit scent marks all around their territory, and the entrances to shelters are covered with piles of faecal pellets, which are a good indication that gundis are present (George 1974). Animals mark and dust-bathe at least once each day in a specific place near the main shelter (P. Gouat & J. Gouat 1987). Gundis may chase conspecific intruders. In captivity, even in large cages, intruders are chased and bitten to death (Eisentraut 1977, P. Gouat & J. Gouat 1987).

Animals in a colony share a common shelter during the night. In addition to this night shelter, numerous secondary shelters used during the day are scattered throughout the home-range. Activity starts at sunrise. Animals come out of the night shelter, and after a period of amicable interaction around the entrances, disperse throughout their home-range to feed individually or in small groups (Gouat 1988a, 1991a). The territory appears as a mosaic of foraging patches adjacent to their rocky shelters. Atlas Gundis spend a large amount of time sun-bathing on the ground or on rocks. Adults and juveniles cooperate to detect predator and conspecific intruders. Animals take turns to watch the surroundings from the top of rocks and to give alarm calls when a potential predator is detected (Gouat & Gouat 1989). Alarm calls are typically simple, monosyllabic chirps which are emitted in quick succession (up to 20 at a time) (George 1981a), but they vary according to the age of the emitter and the circumstances (Séguignes 1979, Gouat *et al.* 1985). On hearing alarm chirps, members of the colony stop their activity and stay vigilant. The sudden appearance of a predator elicits one or two very loud chirps, and all the members of the colony run into shelters. Sound emissions are numerous and varied. The repertoire includes audible range communication (vocalizations, tooth chattering and foot drumming) and some ultrasonic vocalizations (Gouat *et al.* 1985). These sounds are mainly displayed during interactions between conspecifics.

At mid-day, animals rest in the shade or inside the shelters, individually or in small groups. The length of the resting period depends on the ambient temperature. In the hot period (Apr–Sep) in the southern part of the Aures Mts, this resting period lasts from 10:00h until 16:00h. During the cold period (Dec–Feb), or in high elevation sites, resting periods may be absent or may last only one hour (Gouat 1991a). In the late afternoon, animals forage again. Around sunset, they return individually to the main shelter. Interactions are rare at this time except when there is a change of night shelter. One animal may stay at the entrance of the old night shelter and drive the incoming animals to the new night shelter (Gouat 1988a).

In the semi-desert sites of Aures Mts, reproduction starts in Dec. It begins with the exclusion of supernumerary ♂♂ by both the ♀♀ and the reproducing ♂ (Gouat 1988a). This time of the year is one of the rare occasions when gundis are aggressive (P. Gouat & J. Gouat 1987). Copulation may occur outside the shelter (Gouat 1985). Prior

to mating, ♂ approaches ♀ by walking with measured tread with the head bent down slightly, and emits a sexual trill of low intensity (Gouat *et al.* 1985). He sniffs the genital area of ♀. Mounting is followed by some long pelvis thrusts, which precede ejaculation. After ejaculation, ♂ remains on ♀ for ca. 30 sec. In natural conditions, ♂♂ have been observed ejaculating five times during a 45 min period with the same or different ♀♀ (Gouat 1985).

Reproduction and Population Structure Polyoestrous. Two litters are produced each year. In the semi-desert sites of Aures Mts, reproduction begins in late Dec. First litters born in late Feb to early Mar. The birth of young is preceded by a prepartum oestrus (Gouat 1985; see also *C. vali*). Second births occur between late Apr and mid-May. In high altitude sites of the Aures Mts, this reproductive schedule is delayed by two months. Females have two litters per year only under favourable conditions, and scarcity of food may preclude any reproduction and promote the exclusion of supernumerary ♂♂ (Nutt, 2005). Gestation: 73 days. Litter-size: 2 (1–3, n = 17; Gouat 1985). At birth, young are precocial, fully furred, with the eyes and ears open and functional, and able to walk and to chew solid food (Gouat 1985). Birth-weight: 29.9 ± 11.9 g (range 18–40 g, n = 15; Gouat 1985). Weaning: ca. Week 6. Males and ♀♀ do not breed until the reproductive season following their birth, when aged 7–9 months of age (Gouat 1985). Detailed physiological studies on reproduction are required.

Communal nursing is the rule, but young have seldom been observed sucking any ♀♀ other than their mother (J. Gouat & P. Gouat 1987). Young gundis emit an extension trill when approaching their mother, or when the mother leaves them after feeding (Gouat *et al.* 1985). This vocalization accompanies lordosis and anogenital eversion by the young. The extension trill is attractive to adults and may elicit similar trills in other young animals (J. Gouat & P. Gouat 1987). Young animals emit a modulate trill during sucking (Gouat *et al.* 1985). During their first week, young animals remain near the main shelter watched over by an adult ♀ or a juvenile. Adults may carry the young animals in their mouth, one by one, from one shelter to another (J. Gouat & P. Gouat 1987). At the end of the second week, play behaviour (running and head-shaking) and young vocalizations tend to disappear, and agonistic behaviour develops. At three weeks of age, young animals display most behavioural patterns of the adult but sexual behaviour remains absent until the next reproductive season (J. Gouat & P. Gouat 1987). Young animals from about two weeks of age feed mainly on vegetation, but weaning seldom occurs before six weeks of age (Gouat & Gouat unpubl.). Females may supplement young with water through long-lasting mouth to mouth contact (Gouat 1988a).

Three types of population structure have been observed dependent on the bioclimatic conditions. (1) In high altitude habitats, and in habitats with a Mediterranean climate, where mean annual rainfall is ca. 400 mm and food resources are abundant from spring to autumn, high levels of reproduction and a high turnover of the population are observed. Colonies in these habitats, however, may disappear suddenly if devastated by summer storms or by a long period of snow cover during winter (Séguignes 1979, Gouat & Gouat 1983). (2) In semi-desert habitats, populations are more stable, and the level of reproduction is correlated with the abundance of resources. Summer is the most difficult period of the year for gundis because the vegetation becomes dry and sparse. When the conditions are good enough, and

the resources remain abundant, mortality may be low during summer. In this case, in summer or autumn, a group composed of adults and juveniles may migrate to establish themselves in a vacant site (Gouat 1988b). (3) In desert habitats on the edge of the Sahara Desert, where mean annual rainfall is less than 100 mm, social units are generally composed of only one breeding pair. Generally, animals are unable to survive in the desert habitats when there is more than one year without any rain. The maintenance of populations under these conditions depends primarily on recolonization from more favourable sites (Gouat & Gouat 1982, Séguignes & Vernet 1998).

Predators, Parasites and Diseases Gundis are hunted and eaten by humans in the Maghreb. The most dangerous predators are snakes because they are able to enter the rocky shelters of gundis, even during the night. The presence of a large adder (Daudin's Viper *Vipera lebetina*), 1.20 m long, caused a colony of gundis to change their main shelter and to modify the way they used their home-range (Gouat 1991a). Other predators are dogs, foxes, birds of prey and ravens (Séguignes 1979, Gouat 1988a).

Conservation IUCN Category: Least Concern.

Ctenodactylus vali THOMAS'S GUNDI

Fr. Goundi de Thomas (Goundi du Sahara); Ger. Thomas Gundi

Ctenodactylus vali Thomas, 1902. Proc. Zool. Soc. London 1902: 11. 'Wadi Bey' (NW of Bonjem, Tripoli), Libya.

Taxonomy Corbet (1978) included *vali* as a synonym of *gundi*, but George (1982) listed *vali* and *gundi* as separate valid species (see also Dieterlen 2005c). The form *joleaudi* (originally described as a species, *C. joleaudi*) is considered to be a subspecies of *vali* by Petter (1961) and subsequent authors. Synonyms: *joleaudi*. Subspecies: none. Chromosome number: 2n = 40 (George 1979b).

Ctenodactylus vali

Description General appearance of a small guinea-pig with a short hairy tail and small ears. Pelage very dense and soft. Dorsal pelage buffy-brown with dull grey underfur. Ventral pelage yellowish-grey. Head flat and broad. Forehead narrow and slightly hooked. Muzzle short with long black vibrissae. Nostrils naked and black. Eyes large and round surmounted by long vibrissae. Ears flattened on the head, oval, black inside bordered by a dense fringe of short stiff whitish-grey hairs. Fore- and hindlimbs short; four digits on each foot. Digits of the hindfeet are surmounted by comb-like bristles. Claws sharp, not reaching the ground in normal position. Tail relatively short (ca. 102% of HF), usually hidden by pelage of rump and not visible. Skull: see family and genus profiles; each upper incisor with single groove; angular process of mandible elongated posteriorly forming the most posterior part of the mandible (as in *Massoutiera*, cf. *Felovia*, *Pectinator*); hugely inflated auditory bullae (ca. 17.9 mm, 39% of GLS), distance between bullae ca. 7 mm. Emits chirp alarm call when disturbed. Mean length of faecal pellets: 7.9 (7.3–8.2) mm. Nipples: 2 + 0 = 4.

Geographic Variation None recorded.

Similar Species

C. gundi. HB on average larger; forehead large and straight; whistle alarm call; less inflated auditory bullae; mean length of faecal pellets >9.5 mm; partially parapatric.

Massoutiera mzabi. HB similar; tail relatively longer; present in northern Sahara; allopatric.

Distribution Endemic to Africa. Northern edge of Sahara Arid BZ. Distributed in two discrete and widely separated areas of NW

Africa: (1) Algeria and Morocco in the west, and (2) Libya in the east. Morocco: hamada of Wadi Ziz. Algeria: Saharan Atlas from Beni Ounif to Bechar, basin of Wadi Saoura, and hamada of Wadi Guir, Ougarta Mts. Libya: Tripolitania, transitional desert between Soda Mts and the Gulf of Sirte (Ranck 1968). Often parapatric with *C. gundi*. See also below.

Habitat Wide range of rocky desert habitats such as mountain slopes, edges of hamadas, wadis, rift and small mountainous massifs. Also found in semi-desert areas, on the southern slopes of the Saharan Atlas in Algeria and SE Morocco.

Abundance Generally sparsely distributed, but high density may be observed under favourable climatic conditions during the breeding period (e.g. 18 animals/ha; George 1981a).

Adaptations Thomas's Gundis are diurnal and have similar activity patterns to Atlas Gundis: they are active at sunrise and in the early morning, rest at the hottest time of the day, and are active again in the afternoon before sunset. Thomas's Gundis are parapatric with Atlas Gundis on the western edge of the Saharan Atlas and in the south-eastern part of Morocco. In semi-desert habitats, the highly structured occupation of space displayed by Atlas Gundis prevents any extension of the geographic range of Thomas's Gundis further to the west. However, Thomas's Gundis are capable of rapid colonization of sites left vacant by Atlas Gundis following a period of severe drought (Gouat 1988b). The present distribution of Thomas's Gundis in two isolated areas of distribution is best explained by competition with Atlas Gundis and the climatic fluctuations of the Sahara Desert. The relationships between the two species may be explained as follows (Gouat 1988a):

- (1) *Ctenodactylus gundi*, thought to belong to the ancestral species, originally occupied their present range. Following an extension of the Sahara Desert to the north, populations of *Ctenodactylus gundi* gradually moved away and settled in the northern mountains (e.g. Tel Atlas Mts in Algeria). Several rocky corridors may have allowed this resettlement from southern sites to northern sites (e.g. Hodna Mts in Algeria).
- (2) *Ctenodactylus vali* appears to have evolved in one of the populations of *Ctenodactylus gundi* remaining in the Saharan Atlas, in response to the drought caused by the extension of the Sahara Desert to the north. This new species extended its range throughout the range occupied previously by *Ctenodactylus gundi* where desert conditions prevail.
- (3) Regression of the Sahara Desert to the south enabled *Ctenodactylus gundi* to return to its previous range, and as a consequence, the range of *Ctenodactylus vali* became smaller and restricted to more arid desert habitats. As a result, the range of *Ctenodactylus vali* was split into two parts and the species is present only in habitats where *Ctenodactylus gundi* is unable to survive.

Foraging and Food Herbivorous, feeding mainly on grasses and herbaceous plants. The diet encompasses food plants such as *Eremophyton chevallieri*, *Amberboa leucantha*, *Cymbopogon* sp. and *Aristida* sp. (George 1974). Animals forage mainly in early morning and late in the afternoon, alternating foraging with resting. Animals pick up food

items while they travel through their home-range, without having any clear foraging places. The area of foraging each day varies from 20 m² to 275 m² (Gouat 1988a).

Social and Reproduction Behaviour Thomas's Gundis, in contrast to Atlas Gundis, are mainly solitary; social bonds are weak, and animals behave as 'floaters' for a large part of the year. At the end of autumn, ♀ settles at a place where she will produce her young. Several ♂♂ may try to join ♀, but only one ♂ will succeed. A familiarization period is necessary for ♂ to become accepted by ♀. In captivity, reproduction was successful in groups composed of one ♀ and 2–3 ♂♂ (Grenot 1973); ♂♂ develop a hierarchy (George 1978b). In captivity, confrontation between unfamiliar animals may cause the death of the intruder (Grenot 1973, Gouat 1988a). During these agonistic encounters, animals emit different vocalizations, including the 'trilled whistle' and the 'repeated whistle', and non-vocal sounds such as foot-drumming and tooth-chattering (J. Gouat 1991). The repeated whistle is composed of a repetition of short whistles (mean frequency of the plateau: 4.5 KHz; each unit lasts between 0.12 and 0.5 sec). This vocalization is also displayed in the case of a sudden alert and is named the 'alarm call' by George (1981a); on hearing this call, conspecifics respond by adopting an alert posture, or by disappearing inside a shelter. The trilled whistle is emitted only in an agonistic context. It consists of a modulate whistle followed by a trill. The trilled whistle is emitted alone or coupled with the alarm call.

Thomas's Gundis have two litters each year (see also below). In Dec in Djeniene Bou Rezg (Beni Ounif region, Algeria), individuals settle in a suitable habitat after several months of nomadic existence and become sedentary. A ♀ and several ♂♂ establish a territory where ♀ will later give birth to her young. By Jan, ♀ and one of the ♂♂ have developed a social bond; and the supernumerary ♂♂ have disappeared. The pair may spend the night in a common shelter but each forages independently. First copulation occurs in the days following pair formation. Male stays with ♀ during gestation but leaves her soon after the parturition oestrus and no later than the birth of the first litter in Jan–Mar. Young animals are precocial but have difficulty in moving around and remain close to the shelter. Even before they are weaned, the mother leaves her young at night. She joins them in the morning, and may spend the afternoon rest with them. Young animals emit a calling trill quite similar to the extension trill of the Atlas Gundi (J. Gouat 1991), but without lordosis or anogenital eversion by the young. This vocalization attracts the mother and the littermates. Littermates continue to use a common shelter during the night. Young animals of the first litter disperse before the birth of the second litter in Apr–May. In captivity, mothers may become aggressive towards their young of the first litter in the days preceding birth of the second litter. In natural conditions, however, dispersion does not seem to be caused by the mother. Young animals disperse simply by extending their home-range. The mother uses a similar strategy with her second litter. Even while she is still lactating, the mother spends the night alone. She forages on her own, and shortly before her young are weaned, she increases her home-range significantly. In Djeniene Bou Rezg (Beni Ounif region, Algeria), the size of the daily home-range varies from 100 to 500 m² in Dec–Mar, and increases to 1125 m² in May and Jun. At this time of the year, the mother is still lactating. There is no significant correlation between the size of the daily home-range, either with food abundance or with the presence

of young. From day to day, animals use different parts of their habitat and the percentage of overlap between the daily home-range on two consecutive days varies from 12% to 33%, with a minimum in May and Jun. In the early summer, mothers leave their reproductive home-range and become nomadic. The young animals may stay for a while on their natal home-range, but soon become nomadic and solitary. Animals become sedentary again in Dec, with the beginning of the next reproductive season.

Reproduction and Population Structure Two litters per year under favourable conditions; first litter in late Jan–Mar; second litter Apr–May. Gestation: 2 months. Litter-size: 2 (1–3), $n = 21$ litters (combined data from Grenot 1973, George 1978b, Gouat 1988a). Females are lactating and pregnant with the second litter at the same time. Young precocial, fully furred, with eyes and ears open and functional at birth. Weaned: 1–2 months. Young reach sexual maturity and adult size in Dec when aged 7–9 months. In times of severe drought (more than one year without rain), there is no sedentary period and no reproduction. First copulations occur at the end of the autumn (late Nov–Jan). The period of mating may vary between animals of a given region. In the Taghit region, two ♀♀ were captured 20 km apart during the same week of Mar, and one gave birth four weeks before the other (Gouat 1988a). As in Atlas Gundis, a prepartum oestrus is suspected for the second copulation. Female is able to store spermatozoa in her genital tract for at least two months, and to use these spermatozoa without further copulation in order to produce a replacement litter (Gouat 1986). Young animals disperse soon after weaning and recolonization of vacant sites occurs rapidly (Gouat 1988b).

In times of severe drought, reproduction stops and the density of local populations decreases slowly. At such times, Thomas's Gundis may extend their home-range in order to find sufficient resources

to survive. After four years without significant rainfall, Thomas's Gundis were still present in the Beni Abbes region but at a very low density (Gouat & Gouat 1984). When the climatic conditions became favourable again, reproduction recommenced (Gouat 1988a).

Predators, Parasites and Diseases Preyed upon by humans, shepherd's dogs, foxes, birds of prey, snakes (Gouat 1988a) and jackals (George 1974).

Conservation IUCN Category: Data Deficient.

Probably not threatened. Human population density is very low in the geographic range of the species; any decreases in population density are probably due to climatic changes.

GENUS *Felovia*

Felou Gundi

Felovia Lataste, 1886. Le Naturaliste 7 (36): 287. Type species: *Felovia vae* Lataste, 1886.

Felovia vae.

Felovia is a monotypic genus, restricted to the semi-desert rocky habitat of the Felou Hills of the upper Senegal R. in Mali and Mauritania. Originally proposed as a subgenus of *Massoutiera* but recognized as a valid genus by Thomas (1913) and St Leger (1931). Characters of the genus include: palate extends posteriorly to the cheekteeth, toothrows converge anteriorly, upper molar teeth simple with large infoldings on both sides (Figure 100), and tail about double the length (ca. 221%) of the hindfoot (Misonne 1974); further details are given in the species profile. The single species is *Felovia vae*.

Patrick Gouat

Figure 100. Skull and mandible of *Felovia vae* (BM 19.7.7.3698).

Felovia vae FELOU GUNDI

Fr. Goundi du Félou; Ger. Felou-Gundi

Felovia vae (Lataste, 1886). Le Naturaliste, 7 (36): 287. Upper Senegal River, Felou Hills, Medine, south of Kayes, Mali.

Taxonomy Originally described in the genus *Massoutiera*. Phylogenetic evidence suggests this species is closely related to *Massoutiera mzabi* (George 1979a, 1985a). Synonyms: none. Chromosome number: $2n = 36$ (George 1979a).

Description General appearance of a small guinea-pig with small ears and a short movable hairy tail. Pelage very dense and soft. Dorsal pelage reddish-brown. Ventral pelage russet. Head flat and broad. Ears small, with a whitish tuft at the base but without white on the back of the ear; flattened on the head. Fore- and hindlimbs short; four digits on each foot. Digits of the hindfeet surmounted by comb-like bristles. Tail relatively long (ca. 221% of HF), longer than in other gundis (except *P. spekei*). Tail is folded back on the rump when the gundi is at rest, but begins to flick as soon as the gundi begins to move. Skull: see family and

genus profiles; each upper incisor with single groove; angular process of mandible not elongated posteriorly; auditory bullae not greatly inflated (ca. 13.8 mm, 29% of GLS, least inflated of all species of gundis). Mean length of faecal pellets: 10.6 (10.0–10.9) mm. Nipples: $2 + 0 = 4$.

Geographic Variation None recorded.

Similar Species

Massoutiera mzabi. Upper incisors not grooved or slightly grooved; auditory bullae greatly inflated. All other species of gundis are allopatric.

Distribution Endemic to Africa. Sahel Savanna BZ. Known only from Felou Hills, upper Senegal R. in Mali, and the Tagant and Adrar regions in Mauritania. Suspected to occur in Senegal.

Habitat Long deep fissures of ancient sandstone hills, in semi-desert habitats with some trees (e.g. *Adenium obesum*, 2 spp. of fig trees) and shrubs (*Tephrosia mossiensis*) (George 1974). In Mauritania, animals have been found in an oasis on the rocky banks of wadis, on rocky mountain slopes, on the edges of hamada (F. Colas pers. comm.) and on gueltas (i.e. water ponds) where they drink free water (Vale *et al.* 2012).

Abundance Very limited geographic distribution, but in selected localities up to 25 animals/ha (George 1981a).

Remarks Herbivorous. During the dry season (Mar) feeds on leaves of a leguminous shrub *Tephrosia mossiensis*, dropped petioles of fig trees, dry grass and seeds (George 1974). Food resources fluctuate seasonally. Felou Gundis lives in family groups, not far from other family groups. They are noisy animals and in alert situations they emit repeated ‘chee-chee-chee’ calls (George 1981a). They occupy the same shelters for a long time; in 1972, they were still present at the same site where Lataste found them in 1885 (George 1974). Births recorded between mid-Dec and Jan. One young per litter (George 1978b). African Wild Cats *Felis sylvestris* are likely predators (George 1974). See Rosevear (1969) for further information.

Felovia vae

Conservation IUCN Category: Data Deficient, previously assessed as Vulnerable.

Felou Gundis are the most threatened of all species of gundis (but see Abundance above). They are not preyed on by humans in Mauritania.

GENUS *Massoutiera*

Mzab Gundi

Massoutiera Lataste, 1885. Le Naturaliste 7 (3): 21. Type species: *Ctenodactylus mzabi* Lataste, 1881.

A monotypic genus distributed in desert and semi-desert rocky habitats in the Sahel Savanna BZ and the Sahara Arid BZ. The type species, although originally named *Ctenodactylus mzabi* by Lataste (1881), was transferred by him to his new genus, *Massoutiera*, on the basis of the bilobate pattern of the upper molar teeth. Characters of the genus include: palate extends posteriorly to the cheekteeth, toothrows converge anteriorly, upper molar teeth simple with narrow infoldings on both sides, and tail about one and a half times the length (ca. 148%) of the hindfoot (Misonne 1974); further details are given in the species profile. The single species is *Massoutiera mzabi*.

Patrick Gouat

Massoutiera mzabi MZAB GUNDI

Fr. Goundi du Mzab; Ger. Sahara-Gundi

Massoutiera mzabi (Lataste, 1881). Bull. Soc. Zool. de France 6: 214. Ghardaia, Mzab, Algeria.

Taxonomy Two other species have been described in this genus (*Massoutiera haterti* and *Massoutiera rothschildi*), but although there are slight differences in the two forms, similar differences may be observed within a single population (Petter & Roche 1958). Synonyms: *harterti*, *rothschildi*. Subspecies: none. Chromosome number: $2n = 36$ (George 1979b).

Description General appearance of a small guinea-pig with small ears and a short, movable hairy tail. Pelage very dense and soft. Dorsal pelage cream to reddish-brown. Ventral pelage paler. Young have a pinker colouration than their parents. Head flat and broad. Forehead large and straight. Muzzle short with long black vibrissae. Nostrils naked and black. Eyes large and round surmounted by long vibrissae.

Ears flattened on head, oval, black inside bordered by a dense fringe of short stiff whitish-grey hairs. Fore- and hindlimbs short; four digits on each foot. Digits of the hindfeet are surmounted by comb-like bristles. Claws are sharp, not reaching to the ground in normal position. Tail of medium relative length (ca. 148% of HF), longer than in *Ctenodactylus* spp. but shorter than in *Felovia vae*; tail conspicuous (with flicking movements) when gundi is moving. Skull: see family and genus profiles; each upper incisor with single faint groove or without groove; angular process of mandible elongated posteriorly, but not to the extent as in *Ctenodactylus*; auditory bullae hugely inflated (ca. 18.2 mm, 40% of GLS) (Figure 101). Mean length of faecal pellets: 7.3 (6.6–7.9) mm. Nipples: $2 + 0 = 4$.

Geographic Variation None recorded.

Similar Species

Ctenodactylus gundi and *Ctenodactylus vali*. Tail smaller, less visible; unilobate pattern of the upper molar teeth.

Felovia vae. Tail longer; upper incisors each with single groove; less inflated auditory bullae.

Pectinator spekei. Tail similar size; ears only partially flattened on the head; occurs only on the Horn of Africa. *Pectinator spekei* and *Felovia vae* are allopatric, and there is no risk of confusion with *M. mzabi* in the field.

Distribution Endemic to Africa. Sahara Arid BZ (northern edge) and Sahel Savanna BZ of NW Africa. Range discontinuous in Algeria, Libya, Mali, Niger and Chad. Algeria (north): Mzab region, Oued Mya Bassin, Tademaït. Algeria (south): Mouydir, Tefedest, Hoggar (= Ahaggar) Mts and Tassili n' Ajjer. Libya: Maghides Plateau, Akakus, Massak Mallat, Massak Mastafat, Al Haruj al Aswad, Djebel Sawda, Djebel Al Hasawinah. Mali: Adrar des Ifoghas. Niger: Aïr Massif. Chad: Tibesti Massif. The distribution in Libya is not shown on the map.

Massoutiera mzabi

Because of the close phylogenetic relationship of this species to *Felovia vae*, and its behavioural characteristics (Gouat 1991a), it is highly probable that *Massoutiera mzabi* evolved in the Sahel and spread northwards across the Sahara when the climate was less arid. The present geographical range of the species is discontinuous and is probably a relict of a formerly more widespread distribution (Jaeger 1977b, George 1988).

Habitat Mountainous regions of deserts and semi-deserts where rocks are present, but also in rolling hills of Mzab, and on the edges of hamadas in the Wadi Mya basin and Tademaït.

Abundance Patchily distributed in family groups (see below), and never abundant. Isolated animals are common, mainly during the summer. Density in the Mzab region (Algeria): 0.3–3.2 animal/ha (George 1981a, Gouat 1988a).

Adaptations See family profile.

Foraging and Food Herbivorous. Animals forage individually but may forage close to each other. In the Mzab during winter (Nov–Mar), they forage continuously from sunrise to sunset. In contrast, during the summer (Apr–Sep) they are partly nocturnal – foraging begins before sunrise and continues until 10:00h, when animals retreat into the shade or into their rocky shelters; foraging resumes in late afternoon and may continue until after sunset (Gouat 1991a). There is no specific place for foraging; animals collect food items while they travel through their territory.

Principal foods are the leaves, flowers, seeds and stalks of several species of herbs and grasses including *Moricandia arvensis*, *Reseda villosa*, *Launea angustifolia*, *Stipa retorta*, *Peganum harmala*, *Chrysanthemum macrocarpum*, *Centaurea incana*, *Limonium sinuatum*, *Scabiosa arenaria*, *Odontospermum pygmaeum* (George 1988).

Social and Reproductive Behaviour In the Mzab region of Algeria, adult ♀♀ are sedentary and territorial. An adult ♀ occupies a permanent territory (1000–2000 m²) throughout the year. In autumn (Sep–Dec), ♂ joins ♀ in her territory, and stays with her until the first mating (Nov–Dec) and the birth of the first litter (Jan–Mar). Depending on food availability, he remains with the ♀ until at least the time of the second mating (Mar–Apr), and at most until the beginning of summer (Jun). During the period of cohabitation, ♂ and ♀ cooperate to actively defend the territory against conspecific intruders. Mzab Gundis may modify their use of space from one day to another; night and day shelters may differ every day. An alarm call may be emitted in response to a potential predator. This vocalization is a whistle that begins with a sudden decrease of frequency from an ultrasonic frequency far exceeding 16 KHz, and then reaches a plateau at 11–13 KHz. When the animal is worried by an unusual situation, the frequency of the plateau may fluctuate between 8 and 12 KHz. Both adults and juveniles emit alarm calls. The same vocalization is used during agonistic encounters.

After the birth of the young, ♂ may watch them from a distance but rarely interacts with them during their first month of life. During this period, the young remain in the vicinity of their shelter. During the day or at night, ♀ may carry her young, one at a time, in her mouth from one shelter to another, holding the young across its body. During

daytime, the mother comes occasionally to feed the young and seems to spend at least a part of the night with them. This maternal behaviour appears to serve as a defence against predators (Gouat 1988a). In the presence of their mother, young gundis emit a 'modulated whistle', part of which is a 'hiss'. The whistle starts at 2 KHz and ends as an ultrasonic vocalization far exceeding 16 KHz, and is emitted in successive pulses, each lasting 0.15–0.35 sec. The 'modulated whistle' appears to have the same function as the 'extension trill' of the Atlas Gundi. When the young grow older, they become more mobile and follow the mother when they wish to suck. During exploration, juveniles emit low frequency chuckles (1–4 KHz) (J. Gouat pers. comm.). Juveniles interact amicably with both adult ♂♂ and ♀♀. With the arrival of the second litter, ♀ becomes aggressive towards her first young in order to avoid contact between juveniles and her new young. Juveniles are not aggressive to the young. Young of both litters remain within the territory of their mother until the beginning of the summer. Juvenile ♂♂ then disperse, while juvenile ♀♀ tend to stay with their mother for a longer time and try to establish themselves in a vacant territory near their mother. The formation of a group of related ♀♀ seems to be possible.

Reproduction and Population Structure Two litters each year in the Mzab region, Algeria. First mating: Nov–Dec. Birth of first litter: Jan–Mar; second litter: Apr–May. Gestation: ca. nine weeks (captive animal; Gouat 1988a). Litter-size: 2 (1–3), $n = 17$ litters (combined data from George 1978a, Gouat 1988a). Data from other localities is inconclusive: at Mt Baguezan (Aïr, Niger), three ♀♀ with fetuses were captured in May; at Hoggar (Algeria), one ♀ with two well-developed fetuses obtained in mid-Apr (Thomas & Hinton

1921); at Al Haruj al Aswad (Libya), one ♀ with a ca. two-week old young in late Dec.

Predators, Parasites and Diseases Preyed on by humans, canids, birds of prey and snakes (Gouat 1988a).

Conservation IUCN Category: Least Concern.

GENUS *Pectinator*

Speke's Pectinator

Pectinator Blyth, 1856. Journ. Asiatic Soc. Bengal, for 1855, (2) 24: 294 [1856]. Type species: *Pectinator spekei* Blyth, 1855.

Monotypic genus distributed in desert and semi-desert rocky habitats in Ethiopia, Eritrea, Djibouti and Somalia. The characters of the genus include: ears partially flattened on top of head (all other species 'flattened'); palate does not extend posteriorly to the cheekteeth (cf. all other genera of gundis), tooththrows more or less parallel and not converging anteriorly; upper molar teeth simple

with narrow infoldings on both sides, and tail about double the length (ca. 224%) of the hindfoot (Misonne 1974); further details are given in the species profile. The single species is *Pectinator spekei*.

Patrick Gouat

Pectinator spekei SPEKE'S PECTINATOR

Fr. Pectinator de Speke; Ger. Buschschwanz-Gundi

Pectinator spekei Blyth, 1856. J. Asiat. Soc. Bengal for 1855 (2) 24: 294. Between Goree Bunder and Nogal, Somalia.

Taxonomy Synonyms: *legerae*, *meridionalis*. Subspecies: none. Chromosome number: $2n = 40$ (George 1979b).

Description General appearance of a small guinea-pig with ears only partially flattened on the head, and a short, movable hairy tail. Pelage very dense and soft. Dorsal pelage ashy-grey, suffused with black or brown. Flanks greyish. Ventral pelage greyish-white. Head flat and broad. Muzzle short with long black vibrissae. Ear broadly

ovoid, almost naked, with a fringe of whitish hairs on anterior margin. Fore- and hindlimbs short; four digits on each foot. The digits of the hindfeet have three-tiered combs (George 1978a). Tail hairy and long for a gundi (ca. 224% of HF); white on the basal half, black on terminal half with white tip; tail conspicuous even when gundi is resting. The tail appears whitish along its middle, with two lateral black lines externally fringed with dull white. Skull: see family and genus profiles; each upper incisor without groove; angular process of mandible

Pectinator spekei.

short, not reaching level of coronoid process; auditory bullae moderately inflated (ca. 14.9 mm, 33% of GLS) (Figure 102). Mean length of faecal pellets: not known. Nipples: $2 + 0 = 4$.

Geographic Variation None recorded.

Similar Species No other species of gundi lives on the Horn of Africa.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from rocky habitats in Ethiopia, Eritrea, Djibouti and Somalia.

Habitat In Ethiopia, Speke's Pectinator inhabits volcanic and limestone rocky cliffs in desert or semi-desert areas. Altitudinal range: 0–1200 m (Yalden *et al.* 1976). Also lives in man-made rocky escarpments bordering roads (George 1974). Recorded up to 1950 m in N Somalia (N. Redman pers. comm.).

Pectinator spekei

Figure 102. Skull and mandible of *Pectinator spekei* (BMNH 14.2.9.2).

Abundance Speke's Pectinators live at much higher densities than any other species of gundi. In the Danakil Desert of Ethiopia, densities range from 24 to 237 animals/ha (George 1981a).

Adaptations Terrestrial and diurnal. Emerges from rocky shelters at sunrise; maximum activity occurs 0–3 hours after sunrise when ambient temperature is 23–29°C; retreats to shelters during the daytime when temperature reaches 33–34°C and emerges again in late afternoon. Pectinators climb trees and may rest on branches in the shade (George 1974). (See also family profile.)

Foraging and Food Herbivorous. Feeds on dry grass (stalks and seeds), and on leaves of *Caboda rotundifolia*, *Acacia senegal* and *A. seyal* trees (George 1974). Food resources fluctuate seasonally from abundant during the wet season to scarce during the dry season.

Social and Reproduction Behaviour Sociable, living in colonies based on extended family units. When there is a perceived danger, animals emit an alarm call that begins with a chirp, then a long whistle and finally three to six chirps (duration: 0.6–1.5 s, frequency: 1–4 KHz) (George 1981a). Pectinators share their habitat with Rock Hyraxes *Procapra capensis*.

Reproduction and Population Structure In the Danakil desert, births occur from late Aug to mid-Sep after the short wet season. Elsewhere in Ethiopia (no precise locality) births occur in ca. Jan. Litter-size: 1.2 (1–2, n = 6). Birth WT: ca. 20 g; young precocial, fully furred at birth. Time to attain adult weight: ca. 174 days. Growth rate is regular (George 1978b).

Predators, Parasites and Diseases Gabar Goshawks *Micronisus gabar* attempt to catch pectinators (George 1974).

Conservation IUCN Category: Data Deficient.

Family BATHYERGIDAE

MOLE-RATS

Bathyergidae Waterhouse, 1841. Ann. Mag. Nat. Hist., ser. 1, 8: 81.

| | | |
|-----------------------------------|------------------|--------|
| <i>Bathyergus</i> (2 species) | Dune Mole-rats | p. 644 |
| <i>Cryptomys</i> (10 species) | Mole-rats | p. 648 |
| <i>Georchus</i> (1 species) | Cape Mole-rat | p. 662 |
| <i>Heliophobius</i> (1 species) | Silvery Mole-rat | p. 664 |
| <i>Heterocephalus</i> (1 species) | Naked Mole-rat | p. 667 |

The Bathyergidae is a polygeneric family, distributed throughout most of tropical and sub-tropical sub-Saharan Africa, in habitats ranging from open forest to savannas and semi-deserts. All species in the family are subterranean, living in soils that range from soft coastal sands to soils that are extremely hard when dry. There are five genera and at least 15 species, all endemic to Africa (Ellerman 1940, De Graaff 1964a, 1981, Skinner & Smithers 1990, Faulkes *et al.* 1997b, Bennett & Faulkes 2000). The genera *Georchus* and *Bathyergus* are restricted to South Africa, *Heterocephalus* and *Heliophobius* occur only in eastern Africa, and *Cryptomys* occurs in eastern, western and southern Africa. Several genera are sympatric and syntopic, especially in southern Africa. The Bathyergidae is one of the most specialized families of African rodents, and has been the subject of many studies.

All members of the family show morphological adaptations to life underground. Head and body cylindrical in shape, without distinct neck. Limbs short. Fore- and hindfeet have five digits each and naked soles; the radiale (scaphoid) and intermedium (lunar) carpal bones are separate, a feature unique to Bathyergidae and Ctenodactylidae. Pelage short and thick; longer sensory hairs are present over much of the body and are especially numerous on the head. Skin very loosely attached and, in those genera with hair, can be shaken vigorously (20–25 vibrations/sec) to clean pelage of soil. Digits and outer borders of the feet fringed with stiff hairs. Tail very short and fringed with stiff hairs in all genera except *Heterocephalus*. Eyes very small and unable to form images, usually kept closed. Lacks ear pinnae, opening of external auditory meatus is slightly raised; hearing is good. Nostrils housed in a flat horseshoe-shaped nasal area situated above prominent extra-buccal incisors. Muscular folds, covered with medially directed stiff hairs, meet behind the incisors and keep soil out of the mouth when digging. Skull tends to be stoutly built; infraorbital foramina small and secondarily reduced, varied in shape and dimensions and in the thickness of the bone on the outer wall; cheekteeth (premolars and molars) strongly hypsodont and rooted, number varying in number in the different genera. Upper incisors pro-odont and sharp, with either a single groove on the anterior surface of each incisor (*Bathyergus*) or ungrooved (all other genera). Upper incisors of *Bathyergus* are rooted above the anterior cheekteeth, those of other genera more procumbent and rooted posteriorly to the cheekteeth (Ellerman 1940, De Graaff 1964a, 1981). Lower incisors ungrooved. The angle of the lower jaw strongly flared outwards to allow passage of a specialized portion of the superficial masseter lateralis muscle. The two halves of the mandible not firmly ankylosed, permitting lateral splaying of the lower incisors (Jarvis & Bennett 1991; *contra* De Graaff 1981). Dental formula varied, but usually $I^{1/1}, C^{0/0}, P^{1/1}, M^{3/3} = 20$. *Heliophobius* is unusual because the complete cheekteeth formula (P and M) is $s^{6/6}$, but at any one time it is $5/4$ or $4/4$, and occasionally $4/5$ or $6/6$; the

anterior premolars are usually shed before the posterior molars have erupted. *Heterocephalus* only has three molariform teeth in each ramus and on occasion this is reduced to two. In *Cryptomys*, M^3 erupts early in life, and in *Georchus* M^3 erupts late in life (De Graaff 1981). All cheekteeth are molariform in structure and differ only in size.

All genera are strictly subterranean (see Table 15); individuals live and feed in an extensive network of burrows, the majority of which are superficial foraging burrows running at depths close to those of their food. Deeper burrows link foraging areas with nest, toilet area and, where present, a food store. Loose skin facilitates turning in the tight confines of the burrow. All genera, except *Bathyergus*, are chisel-tooth diggers, biting at the soil face with their sharp rapidly growing incisors. All genera use fore- and hindfeet to push the loosened soil behind them; fringes of hairs on feet and tail help contain the soil as a mole-rat reverses down the burrow and up a side-branch where the soil is disposed of as a mound (or mounds) at the surface (Jarvis & Sale 1971). Except at the inception of mound formation, all genera, except *Heterocephalus*, have a plug of soil between the burrowing animal and the outside. Once the mound is fully formed, the side-branch is packed with soil thereby sealing the burrow system from the surface. Mole-rats are most vulnerable to predation by snakes, birds and small carnivores during mound formation, the only time when an above-ground predator can accurately locate them. Activity patterns appear to vary seasonally, largely in response to temperature changes in superficial foraging burrows; mole-rats show poor ability to entrain their circadian rhythms to light. Peak burrowing activity, and mound formation, occur after rainfall when soil is easily worked. When the soil is very dry, excavated soil is packed into disused sections of the burrow system and not disposed of on the surface (Jarvis & Sale 1971, Jarvis & Bennett 1991).

Mole-rats have little exposure to sunlight and exhibit signs of vitamin D3 deficiency. Nevertheless, unlike most mammals that need vitamin D3 for calcium uptake, mole-rats absorb calcium in the intestine and kidneys via specialized vitamin D3-independent paracellular processes (Buffenstein *et al.* 1994). The diet is high in cellulose and fibre, and is digested by symbiotic micro-organisms in a large caecum and hindgut. Digestive efficiency is high (>80%), facilitating maximum returns for foraging effort (Buffenstein & Yahav 1991a, 1994, Bennett & Jarvis 1995), and is further enhanced by re-ingesting partly digested faecal pellets. This autocoprophagy contributes to digestive efficiency, reinoculates the mole-rat with endosymbionts and provides an additional source of protein and energy from digestion of the microbes themselves. For their size, members of the Bathyergidae have lower than predicted metabolic rates (McNab 1966, Lovegrove 1986, Buffenstein & Yahav 1991b) and long maximum life-spans: >26 years for captive *Heterocephalus glaber* and >12 years for *Cryptomys damarensis* (O'Connor *et al.* 2002, Sherman & Jarvis 2002, J. U. M. Jarvis & N. C. Bennett unpubl.).

Bathyergus, *Heliophobius* and *Georchus* are solitary, each individual aggressively defending its burrow system against conspecifics. All breed seasonally. *Bathyergus* and *Georchus* communicate through the soil by drumming with their hindfeet. Occupancy of a burrow by

more than one animal occurs briefly at mating; young leave the maternal burrow at about two months; 1–2 litters are born during the breeding season (Jarvis & Bennett 1991, Sumbera *et al.* 2003a). In contrast, *Heterocephalus* and *Cryptomys* are social: colonies consist of family units usually with a single reproductive ♀, 1–3 consort ♂♂ and a number of non-reproductive (but not infertile) helpers (Jarvis 1981, Bennett 1988, Jarvis & Bennett 1991, Jarvis *et al.* 1994). New colonies of *Cryptomys* are formed from an out-bred pair and their offspring; the colony fragments on the death of the reproductive animals (Jarvis & Bennett 1993, Jarvis *et al.* 1994, Bishop *et al.* 2004, Burland *et al.* 2004). *Heterocephalus* is strongly xenophobic, frequently inbreeds, and replacement of reproductive animals often occurs from within the colony; occasionally out-breeding may occur (O’Riain *et al.* 1996, O’Riain & Braude 2001). Some *Cryptomys* breed seasonally (e.g. *C. h. hottentotus*) and others aseasonally (e.g. *C. damarensis*; Bennett 1988, Spinks *et al.* 1999). Breeding in *Heterocephalus* is aseasonal. Gestation is long: 56–111 days in *Cryptomys* and *Heliophobius*, and 66–74 days in *Heterocephalus* (Bennett *et al.* 1991). In seasonal breeders, a maximum of two litters are born annually, whereas aseasonal breeders have 3–4 litters each year. In all genera, testes lie abdominally or in inguinal pockets, and there is no development of a scrotum. Non-reproductive ♀♀ have small nipples and a vagina closure membrane. Litter-sizes are usually 2–6 young/litter, but reach 28 young/litter in *Heterocephalus*. Maximum recorded colony sizes are 41 animals for *Cryptomys damarensis* (Jarvis & Bennett 1993) and >300 for *Heterocephalus* (Brett 1991a, S. Braude unpubl.).

Bathyergus dig extensive foraging burrows with their strongly clawed forefeet; other genera bite at the soil with large, rapidly growing, extra-buccal incisors. All feed on underground portions of plants, particularly roots, bulbs, corms and tubers located while digging extensive, superficial foraging burrows. *Bathyergus* and *Georchus* also eat aerial parts of plants by loosening the soil under the roots, and then pulling the entire plant into the burrow. Most genera store small food items in a chamber or blind-ending burrow situated close to the nest. Larger items are eaten *in situ*, often being partly eaten and then left to regenerate (Jarvis & Bennett, 1991). Mole-rats do not drink free water. Solitary genera are usually restricted to mesic habitats where food items are spaced close together and where rainfall is frequent allowing frequent opportunities to burrow. Sociality has enabled *Cryptomys* and *Heterocephalus* to also inhabit arid regions where food is widely dispersed and patchy and where rainfall is sparse and unpredictable, allowing for only limited opportunities to burrow (Jarvis & Bennett 1993, Jarvis *et al.* 1994). After rainfall, colonies can dig >1 km of foraging burrows in a month, rapidly expanding their home-range while the cost of digging is relatively low. Most of the food needed to sustain the colony until the next rains is located at this time. All species peel their food, holding onto small items of food with their forefeet while eating, with frequent pauses to shake it, or hold it, between their incisors and to brush it with the forefeet. All except *Heterocephalus* balance on the hindfeet while feeding on small items; *Heterocephalus* rests on the elbows.

The Bathyergidae is a monophyletic group currently placed with the suborder Hystricomorpha, infraorder Hystrignathi. The Bathyergidae are the most species-rich of the four African families of the Hystricognatha, which also includes the families Hystricidae, Petromuridae and Thryonomyidae. Bathyergids show a number of unique features. All five genera have a highly flared angle of the lower

jaw, secondarily reduced infraorbital foramina, and unfused carpal bones. Few genera of other families of rodents have such a variable number of cheekteeth (3–6 in both upper and lower jaws) (Ellerman 1940, De Graaff 1981). Closest, but still distant, relatives are the other phiomorph families of the Hystricognathi: Rock Rats (Petromuridae), Cane Rats (Thryonomyidae) and Old World Porcupines (Hystricidae). Fossils from two extinct genera of bathyergids and of *Heterocephalus* date from the early Miocene (ca. 25 mya) in East Africa and Namibia. Molecular evidence also indicates early divergence of *Heterocephalus* and *Heliophobius* from extant members of the family (Allard & Honeycutt 1992, Faulkes *et al.* 1997b, 2004).

Taxonomy of the Bathyergidae, particularly of *Cryptomys*, is under review. *Cryptomys* spp. from C Zambia and around Pretoria, South Africa, show much genetic divergence and several, as yet undescribed, species have been found. Little is known of the relationships of *Cryptomys* spp. from West Africa and Uganda. Additionally, genetically divergent *Heliophobius* have been found in WTanzania and Malawi, and divergent *Heterocephalus* in Ethiopia (Faulkes *et al.* 1997b, 2004). The significance of these genetic divergences is unclear.

The family is traditionally divided into two subfamilies, Bathyerginae and Georchichinae (De Graaff 1981, Allard & Honeycutt 1992) and currently 15 species are recognized (Table 45). The Bathyerginae has grooved upper incisors whose roots originate above the cheekteeth, enlarged forefeet and claws and large body size (up to ca. 2000 g), and contains one genus (*Bathyergus*) and two species. The Georchichinae has ungrooved upper incisors with roots originating behind the molars, forefeet and claws which are not enlarged, and a smaller body size (<500 g), and contains four genera (*Georchus*, *Heliophobius*, *Heterocephalus*, *Cryptomys*) and about 13 species. However, the above subfamilial groupings are not supported by molecular phylogenies, and are not considered here. *Bathyergus* forms either a clade within the paraphyletic Georchichinae or it groups with *Georchus* in a monophyletic clade. Thus it would appear that the long claws on forefeet and grooved upper incisors are derived traits peculiar to *Bathyergus* (Faulkes *et al.* 2004). All molecular studies agree that *Heterocephalus* is basal and divergent in the family. Woods & Kirkpatrick (2005) place the genera *Bathyergus*, *Cryptomys*, *Georchus* and *Heliophobius* in the subfamily Bathyerginae, and the genus *Heterocephalus* in a subfamily of its own, the Heterocephalinae.

The five genera recognized here are:

Bathyergus: silvery to tan pelage with darker mid-dorsal band, colour very variable; head darker with paler areas round the eyes, ears, nose and chin; upper and lower cheekteeth, simple; the only genus with elongated claws and grooved upper incisor teeth; weight up to 2000 g.

Georchus: strikingly marked head and face: black to charcoal head with white patches on muzzle; eyes and ears on top of head; four upper and lower cheekteeth with persistent re-entrant folds; palate extends behind tooththrow; ungrooved upper incisor teeth; weight up to 350 g (1 sp.).

Heliophobius: silver to tan pelage, sometimes lacking white head-patch; up to six upper and lower simple cheekteeth (not usually all present at the same time); palate not extending behind tooththrow; ungrooved upper incisor teeth; weight up to 260 g (possibly 2 spp.).

Heterocephalus: skin pink-brown, lacking a pelage although isolated sensory hairs are present; only genus with long tail; three upper

Table 45. Species in the family Bathyergidae. Arranged alphabetically.

| Species | HB mean (mm) | GLS mean (mm) | Pelage colour | Groove on each upper incisor | Infra-orbital foramen (longest dimension) | Other characters | Notes |
|--------------------------------------|--------------|---------------|---|------------------------------|---|---|---|
| <i>Bathyergus janetta</i> | 205 | 51.9 | Silvery-fawn (variable) | Single | Small, almost round (2 mm dia.) | White eye-ring. Angle of mandible extends posteriorly to skull | South-West Arid BZ (parts) |
| <i>Bathyergus suillus</i> | 281 | 65.1 | Cinnamon-brown | Single | Small, almost round, (2–3 mm dia.) | Pale eye-ring. Mandible as <i>B. janetta</i> | South-West Cape BZ |
| <i>Cryptomys anelli</i> | 121 | 33.9 | Slate-grey (young); golden-ochre (adult) (variable) | Absent | Elliptical, wide at base (n. d.) | White patch on forehead (most) | Zambia (Lusaka region) |
| <i>Cryptomys bocagei</i> | 151 | 31.1 | Grey, silvery-grey | Absent | Small, teardrop (1.5–2 mm) | White patch on forehead | Zambezian Woodland BZ |
| <i>Cryptomys damarensis</i> | 164 | 36.2 | Fawn, brown or black | Absent | Small, teardrop (1.5–2 mm) | Mid-dorsal and mid-ventral stripes | Zambezian Woodland and South-West Arid (Kalahari) BZs |
| <i>Cryptomys darlingi</i> | 145 | 33.3 | Blackish to silvery-grey (variable) | Absent | Small, teardrop (1.5–2 mm) | White ventral stripe or patch | Zambezian Woodland BZ (Zimbabwe, C Mozambique) |
| <i>Cryptomys foxi</i> | 145 | 40.7 | Sepia-brown | Absent | Oval teardrop (1.5–2 mm) | Subcircular white patch on forehead | Highlands of C Nigeria and Cameroon |
| <i>Cryptomys hottentotus</i> | 122 | 30.6 | Cinnamon-buff to dark grey (variable) | Absent | Elliptical (ca. 3 mm) | | Widespread in South-West Cape, South-West Arid, Highveld and parts of Coastal Forest Mosaic BZs |
| <i>Cryptomys kafuensis</i> | 112 | 33.5 | Slate-grey to golden-ochre | Absent | Elliptical (n. d.) | Small conspicuous white patch on forehead | S Zambia |
| <i>Cryptomys mechowii</i> | 190 | 52.0 | Greyish-brown to golden-ochre | Absent | Elliptical (ca. 5 mm) | No white patch on forehead (usually). Bristles on margins of feet | Zambezian Woodland BZ and Southern Rainforest Mosaic |
| <i>Cryptomys ochraceocinereus</i> | 169 | 43.2 | Medium brown | Absent | Round-oval (ca. 2 mm dia.) | Conspicuous round white head patch. White eye-ring | Northern Rainforest–Savanna Mosaic |
| <i>Cryptomys zechi</i> | 167 | 42.7 | Pale cinnamon-buff | Absent | Round-oval (ca. 2 mm dia.) | White patch on forehead | NW Ghana, Togo |
| <i>Georchus capensis</i> | 189 | 48.3 | Russet-brown | Absent | Small, round (ca. 1–1.5 mm) | Distinctive black and white markings on head. White eye-ring | South-West Cape and Highveld BZs |
| <i>Heliophobius argenteocinereus</i> | 161 | 39.1 | Silvery-grey to tan | Absent | Round (dia. 1.5 mm) | White patch on forehead (some). Bristles on margins of feet | Zambezian Woodland and southern part of Somalia–Masai Bushland BZs |
| <i>Heterocephalus glaber</i> | 84 | 21.4 | Naked (no pelage) | Absent | Round, very small (ca. 0.5 mm) | Tail comparatively long (ca. 50% of HB) | Somalia–Masai Bushland BZ (Somalia–SE Kenya) |

and lower cheekteeth; Digit 3 of forefoot longer than Digit 4; ungrooved upper incisor teeth; weight highly variable 25–80 g (1 sp.).

Cryptomys: pelage colour varies from silver, grey, tan, charcoal and black; many have a white head-patch; four upper and lower cheekteeth with only traces of infolding; ungrooved upper incisor teeth; weight up to 600 g. Two groups/subclades have been

identified in this genus, as a result of differences in the infraorbital foramina and in mitochondrial cytochrome *b*. One subclade has small thick-walled infraorbital foramina (at least 6 spp.), the other has elliptically shaped and thin-walled infraorbital foramina (at least 3 spp.).

GENUS *Bathyergus*

Dune Mole-rats

Bathyergus Illiger, 1811. Prodr. Syst. Mamm. Avium., p. 86. Type species: *Mus maritimus* Gmelin, 1788 (= *Mus suillus* Schreber, 1782).

Bathyergus suillus.

This small genus contains two species distributed along the SE and NW coastal regions of South Africa and the SW coast of Namibia. Both are restricted to sandy soils, hence their common name 'Dune Mole-rats'.

Bathyergus contains the largest mole-rats, and is the only genus with the following set of characters: enlarged strongly clawed forelimbs (Digits 2, 3 and 4 bearing largest claws); grooved upper incisors that are less protruding than other genera and are rooted above the anterior cheekteeth; and with the angular process of mandible extending backwards behind the skull more than in all other genera of mole-rats (Ellerman 1940, De Graaff 1981).

Members of the genus dig with strongly clawed forelimbs (the only bathyergids to do so), using the teeth to sever roots that they encounter. When the soil is dry, foraging burrows often run deeper than food items, reducing the risk of these large-diameter burrows collapsing in the very loose sandy soil; the mole-rats dig upwards every now and then to locate their food. Up to 60% of diet is aerial (above ground) parts of plants; dune mole-rats dig up under the plant, isolate or sever the roots, and pull the entire plant underground; some is eaten and some used as nesting. They also eat roots and the subterranean storage organs of geophytes (Davies & Jarvis 1986). Dune mole-rats are solitary, drum with the hindfeet to advertise territory and perhaps to attract mates. There is marked sexual dimorphism: ♂♂ are larger with very thick skin (up to 10 mm) on the ventral surface of neck – perhaps as a protection during fighting for mates. Reproduction is seasonal, with a maximum two litters of 1–6 young/season (Jarvis 1969b, Herbst *et al.* 2004). Occasionally animals are found wandering on the surface, where they are very vulnerable to predators (Davies & Jarvis 1986, J. U. M. Jarvis unpubl.).

The species are distinguished by size, colour of pelage, and skull characters. The two species are allopatric over most of their geographic range but are sympatric near Groenriviersmond and Rondawel (31° S, 18° E) on the west coast of South Africa (Faulkes *et al.* 2004).

J. U. M. Jarvis

Bathyergus janetta NAMAQUA DUNE MOLE-RAT

Fr. Rat-taupe des dunes de Namaqua; Ger. Namaqua-Strandgräber

Bathyergus janetta Thomas and Schwann, 1904. Abstr. Proc. Zool. Soc. Lond. 2: 6. Port Nolleth, coastal Little Namaqualand, NW Cape Province, South Africa.

Taxonomy Originally described as a subspecies of *B. suillus* but De Graaff (1981) believed it to be a valid species, a view followed by later authors and supported by genetic information (Nevo *et al.* 1987, Faulkes *et al.* 1997b). Synonyms: *inselbergensis*, *plowski*. Subspecies: none recognized here although there is considerable geographic variation in size and colour that may indicate the existence of coastal and inland subspecies. Roberts (1951) recognized three subspecies but they were not recognized by De Graaff (1981) because the sample sizes were small. Subspecies: none. Chromosome number: $2n = 54$, $FN = 104$ (Nevo *et al.* 1986).

Description Medium to large mole-rat (although smaller than *B. suillus*). Pelage colour varies geographically (see below). Pelage with silvery sheen. Dorsal pelage silvery-fawn with broad band of dark seal-brown or dark grey from nape of neck to rump. Flanks silvery-grey or seal. Ventral pelage darker than flanks. Long pale-coloured tactile hairs scattered over body. Head dark brown or black, white patch or stripe on muzzle and sometimes on chin. Eyes with white eye-ring. Ear opening often surrounded by white patch. Limbs and feet dark slaty-

grey above, dull white below; strong curved claws. Tail very short (ca. 24% of HB), pink above, white below with long dull white bristles (De Graaff 1981, Skinner & Smithers 1990). Skull rounded (more so than in *B. suillus*); sagittal and occipital ridges small; each upper incisor with a single deep groove; auditory bullae rather swollen; palate does not extend posteriorly beyond the molars; infraorbital foramen small, almost round (2 mm dia.), with thick outer wall. Angular process of mandible extends posteriorly well beyond end of skull. Males on average larger than ♀♀. Nipples: $2 + 1 = 6$.

Geographic Variation Individuals near the coast are smaller and paler in colour (description above). Individuals further inland are larger and may be almost black with silvery flanks.

Similar Species

Bathyergus suillus. HB larger; less contrasting pelage, without sheen; skull much flatter, larger sagittal and occipital ridges, auditory bullae not markedly swollen, and palate extending posteriorly beyond level of M^3 .

Bathyergus janetta

Distribution Endemic to Africa. Recorded in South-West Arid BZ (Namib and Karoo) from near Rndawel in W Northern Cape Province northwards along the coast to the Orange R., and about 90 km into Namibia (Faulkes *et al.* 2004). Inland extends from Springbok and Kamieskroon to Ezelfontein in the Kamiesberg Mts at an altitude of 1350 m (Roberts 1951, De Graaff 1981). Over much of the inland range, occurs in sympatry with *Cryptomys hottentotus*; near Groenriviersmond and Rndawel, the southernmost part of range, occurs in sympatry with *B. suillus* (Faulkes *et al.* 2004).

Habitat Coastal sand dunes and consolidated sandy alluvial soils inland where mean annual rainfall is <400 mm. Vegetation is typical of the Namaqualand Namib Domain of the Succulent Karoo floristic region (Jürgens 1991), with winter rainfall, abundant spring flowers, herbs and grass after good winter rains. These ephemeral plants die down at the onset of the prolonged, hot, dry season, leaving a sparse covering of low shallow-rooted and drought-resistant shrubs with succulent leaves, patches of grass, a variety of succulents and abundant geophytes. Range of habitats within this floristic region is slightly more diverse than in the habitat of *B. suillus* and includes the coastal Sandveld, southern Namib Desert and Richtersveld.

Abundance Occurs in small isolated patches, particularly in the most arid part of range where often associated with seepage areas where geophytes abound. Densities are greatest inland, where the rainfall is higher: up to 44 individuals/km². The mean home-range is 806 m² (range 398–12,438 m², n = 6) (Herbst 2002).

Adaptations Subterranean. Burrow systems are usually 57–175 m in length but may be as long as 250 m; foraging burrows are 250–400 mm below the surface and 107–136 mm in diameter (N. C. Bennett, J. U. M. Jarvis & R. Tharm unpubl.). Method of digging and burrow configuration are similar to *B. suillus*. Nests are located 40–58 cm below ground, each has a single entrance, and nests contain

pieces of grass and outer husks of geophytes; there may be up to five nests per burrow. In the inland part of the range, burrows may overlap, but at different depths, with those of *Cryptomys h. hottentotus* (J. U. M. Jarvis & N. Bennett unpubl.).

Foraging and Food Herbivorous. In spring after the winter rainfall, Namaqua Dune Mole-rats eat aerial vegetation—daisies, grasses and herbs—which is pulled into their burrows. In dry conditions when most of this aerial vegetation has died down, they subsist on geophytes (bulbs, tubers, corms) and also succulent roots and stems of *Herrea* spp. and *Trachyandra* spp.; these succulents are often abundant and probably enable Namaqua Dune Mole-rats to occur in arid regions. Namaqua Dune Mole-rats store food (geophytes and roots) in a side branch in the burrow (1–2 stores per burrow system). Partly eaten roots of *Herrea* plants that are still growing next to the burrows have been found in excavated burrows (N. Bennett, J. U. M. Jarvis & R. Tharm unpubl., Herbst 2002). Most foraging burrows are dug after rainfall.

Social and Reproductive Behaviour Solitary. Territorial drumming is used to inform conspecifics of their presence. More drumming occurs at the onset of the breeding season, presumably to communicate with prospective mates. Drumming is achieved by simultaneously hitting the burrow floor with both hindfeet. Occupancy of a burrow by more than one adult animal has been recorded in May–Aug, possibly indicating the onset of mating (Herbst 2002). Nothing known about reproductive behaviour.

Reproduction and Population Structure Reproduction is seasonal. Individuals become reproductively active towards end of winter and at onset of early spring rains. The concentration of testosterone is raised Jul–Nov, as is oestradiol Jul–Aug and progesterone Jul–Sep (Herbst 2002). Pregnant ♀♀ captured in spring and early summer (Aug–Nov); and ♀♀ with young in Sep–Dec. A newly dispersed juvenile (62 g) captured in Dec. Minimum length of gestation: 52 days (time of capture to birth of litter, n = 2 animals). One, sometimes two, litters per season. Litter-size: 2–7 (n = 13). At birth, young weigh 15.4 g (11.4–19.9 g, n = 9). Solid foods first eaten ca. Day 10. Weaned ca. Day 34. Eyes open Day 14. Inter-sibling sparring begins around Day 44 and young disperse from ca. Day 60 (Herbst *et al.* 2004). One coastal ♀ weighing 198 g was pregnant, indicating the small adult body size in this part of the geographic range (J. U. M. Jarvis unpubl.).

Predators, Parasites and Diseases Mole-snakes *Pseudapsis cana* prey on Namaqua Dune Mole-rats. Large raptors, jackals and other carnivores may be potential predators. No information on parasites and diseases.

Conservation IUCN Category: Least Concern.

Listed as rare in South African Red Data Book (1986). The restricted distribution and damage to the habitat by strip-mining for diamonds on the coast are cause for concern.

Measurements

Bathyergus janetta

HB (♂ ♂): 205 (170–235) mm, n = 9

HB (♀ ♀): 183 (170–205) mm, n = 10
 T (♂ ♂): 47 (41–52) mm, n = 9
 T (♀ ♀): 44 (40–50) mm, n = 10

Bathergus suillus CAPE DUNE MOLE-RAT

Fr. Rat-taupe des dunes du Cap; Ger. Kap-Strandgräber

Bathergus suillus (Schreber, 1782). Die Säugethiere 4: 715. Cape of Good Hope, South Africa.

Taxonomy Originally described in the genus *Mus*. Formerly included *janetta* (now considered to be a valid species). Synonyms: *africana*, *intermedius*, *maritimus*. Subspecies: none. Chromosome number: 2n = 56, FN = 102 (Nevo *et al.* 1986).

Description Large mole-rat, the largest of all subterranean mammals in Africa, with strong curved claws on forefeet. Pelage thick and woolly, without sheen. Dorsal pelage cinnamon-brown,

sometimes with darker mid-dorsal band, hairs black or dark grey at base, cinnamon-brown at tip. Long pale-coloured sensory hairs interspersed in pelage. Flanks paler. Ventral pelage greyish. Head similar in colour to dorsal pelage, with small white markings on muzzle and (in some individuals) on back of head. Eyes small, with pale eye-ring. External ears absent, with pale patch around ear opening. Forelimbs short with large forefeet and strong curved claws (largest on Digits 2, 3 and 4). Tail broad, very short (ca. 18% of HB), fringed on the edge with stiff pale buff bristles. Skull robust and dorsoventrally flattened; well-developed sagittal and occipital ridges; each upper incisor with a single deep groove; palate extends posteriorly to beyond M³; auditory bullae not markedly swollen; infraorbital foramen small, almost round (2 mm dia.), with thick outer wall. Molar teeth simple with re-entrant folds only in juveniles (as in Figure 103). Angle of mandible extends posteriorly well beyond end of skull (Figure 103). Males on average larger than ♀ ♀. Nipples: 2 + 1 = 6.

Geographic Variation Individuals from the drier west coast localities (north of Cape Town) are paler in colour, but often with a slightly darker mid-dorsal band compared with those from the moister south coast localities (Cape Town to Knysna) (De Graaff 1981).

Similar Species

B. janetta. HB smaller; dorsal pelage silvery-fawn with sheen and a darker mid-dorsal band; skull with smaller sagittal and occipital ridges; auditory bullae markedly swollen; and palate does not extend posteriorly beyond the level of M³.

Cryptomys hottentotus. HB much smaller; incisors not grooved; forefeet without elongated claws.

Georchus capensis. Smaller; dorsal pelage russet; head blackish with white muzzle and large white patch around ear opening; incisors not grooved; forefeet without elongated claws.

Distribution Endemic to Africa. South-West Cape BZ. Recorded only from South Africa; ranges from coastal areas of Western Cape Province from near Ronddawel on the Groenrivier (Faulkes *et al.* 2004)

Figure 103. Skull and mandible of *Bathergus suillus* (BMNH 4.2.2.6).

Bathyergus suillus

in the north-west to Knysna on the south coast. Rarely occurs above 300 m. Where sand is more consolidated, may occur sympatrically with *Georchus capensis* and/or *Cryptomys hottentotus*. Near Ronsdale occurs in sympatry with *B. janetta*.

Habitat Loose coastal sands and sandy loams along the coast, and on banks of rivers close to the coast. Favours Sandveld vegetation where grasses, herbs and restionaceous sedges abound.

Abundance Sometimes extremely abundant locally. Density has been recorded as 0.9 mole-rats/ha in coastal fynbos (Davies & Jarvis 1986); and as high as >300 individuals/ha in grasslands and wheat fields so that the entire ground surface is covered by their large mounds (J. U. M. Jarvis unpubl.). Their abundance was noted by Europeans as early as 1660; Van Riebeeck (in his journals) referred to the Berg River region as 'the kingdom of the moles'; he commented that horse riders were forced to keep to rhinoceros trails to prevent the horses from stumbling and throwing their riders or breaking their legs when they stumbled into the mole-rat's burrows.

Adaptations Subterranean. The large size of Cape Dune Mole-rats restricts them to easily worked soils where the energetic cost of excavating soil is lowest. They dig with their strongly clawed forelimbs. Burrows are extensive (up to 420 m), not as finely branching as those of other genera. Foraging burrows are 350–650 mm deep and 150–220 mm in diameter. Nest chambers are often slightly deeper than foraging burrows; nests are lined with grass and twigs and are often associated with blind-ending 'bolt-holes' (>2 m deep) into which an animal retreats if alarmed, blocking the burrow behind it. Blind-ending toilet burrows occur also near the nest chamber, and food stores are sometimes present. Burrow configuration is constantly changing but animals remain in one area (Davies & Jarvis 1986). Burrows may overlap with those of *Georchus capensis* and/or *Cryptomys h. hottentotus*, the burrows of each species being at different

depths (Skinner & Smithers 1990, Jarvis & Bennett 1991). Telemetry studies reveal that animals are active throughout 24 h, with peaks of activity at 12:00h–16:00h (J. U. M. Jarvis unpubl.).

Foraging and Food Herbivorous. The diet consists of up to 60% above-ground vegetation (herbs, grasses, sedges of the family Restionaceae) collected by digging up under the plant and pulling it into the burrow. Bulbs, tubers, roots also eaten (Davies & Jarvis 1986) whenever encountered during digging. Cape Dune-rats rarely forage above ground.

Social and Reproductive Behaviour Solitary and aggressively territorial. Cape Dune Mole-rats communicate through soil by drumming with both hindfeet simultaneously on the ground (two beats, pause, two beats, etc.; J. U. M. Jarvis unpubl.). They make snorting grunts and drum when threatened or alarmed. Vacant burrows are quickly taken over by neighbours. Little is known about reproductive behaviour, and there have been no successful matings in captivity. During courtship, ♂♂ and ♀♀ drum in unison, move soil and lock incisors; ♀ raises her tail and vocalizes while ♂ follows and attempts to mount (J. U. M. Jarvis unpubl.). Marked sexual dimorphism and thick protective skin on the neck suggests ♂♂ fight for ♀♀. Males seem to have more linear burrows than neighbouring ♀♀, possibly providing access to several ♀♀ (Davies & Jarvis 1986). Mean home-range of adults at one site in coastal fynbos was 0.27 ha (0.14–0.35 ha) (Davies & Jarvis 1986); home-range can be much smaller elsewhere when densities are high.

Reproduction and Population Structure Reproduction is seasonal, occurring during the wet winter (Apr–Nov), with pregnancies peaking in Aug. During the reproductive season, testes in ♂♂ change from abdominal to inguinal, but there is no real development of a scrotum. Usually one (occasionally two) litter/season. Gestation: 2 months (estimate). Litter-size: 3.3 (1–6), n = 99. At birth, young weigh 27–52 g (n = 10). Eyes open Day 7. First solid foods eaten ca. Day 15. Weaned ca. Day 30. Inter-sibling sparring begins at Day 12, and later escalates to fighting. Young disperse either above or below ground ca. Day 60–65, when weight is ca. 300 g. Sexual dimorphism beginning to be evident at one year of age, when weight is 420–638 g (n = 4). Smallest wild sexually active individuals at weight of 529 g (♂♂) and 494 g (♀♀) (J. U. M. Jarvis unpubl.). Growth continues for several years. Longevity: >6 years. Sex ratio is parity (M. J. O'Riain & J. U. M. Jarvis unpubl.).

Predators, Parasites and Diseases Despite their large size, even adult Cape Dune Mole-rats are eaten by Mole-snakes *Pseudapsis cana* and probably also by the Cape Cobra *Naja nivea*. Jackals, caracals, other small carnivores and even herons and some raptors, will capture animals working close to the surface or wandering above ground. During the winter, Cape Dune Mole-rats occupying low-lying areas such as temporary vleis, sometimes get flooded out of their burrow systems. They have little resistance to cold and are easy prey to these predators. Ectoparasites include three species of mites, one species of flea, one species of sucking louse and two species of ticks. Three species of endoparasitic worms have been recorded (De Graaff 1964b, 1981). Close to habitations, Cape Dune Mole-rats are often infested with the cysts of the dog tapeworm.

Conservation IUCN Category: Least Concern.

Cape Dune Mole-rats may be pests. They undermine roads, damage earthen dam walls, chew through underground communication cables and irrigation pipes. Their large mounds damage combine harvesters. They are trapped extensively, and eaten by local people.

GENUS *Cryptomys*

Mole-rats

Cryptomys Gray, 1864. Proc. Zool. Soc. Lond. 1864: 124. Type species: *Georchus holosericeus* Wagner, 1842 (= *Bathyergus hottentotus* Lesson, 1826).

Cryptomys hottentotus.

The genus *Cryptomys* contains ten species distributed throughout western, central and southern Africa, but is absent from the Horn of Africa, tropical rainforests of central and West Africa, and the Sahara. It is distributed in a wide range of soil types – fine clays to coarse sand and occasionally brecciated soils – and occurs in a variety of biomes, from mesic to arid.

These mole-rats are of intermediate size, being larger than *Heterocephalus* but smaller (except for *C. mechowii*) than *Bathyergus*, *Georchus* and *Heliophobius*. Pelage colour is cinnamon, fawn, grey and black amongst the different species. The muzzle is flat; tail is shorter than the hindfeet; the toes of fore- and hindfeet, and their claws, are short. The skull is less robust than in *Bathyergus*. Cheekteeth are simple folds in adults. The premaxilla bones, housing the incisors, do not bulge out laterally as much as in *Bathyergus* and *Georchus*. The jugal fits into an elongate groove on the outer upper side of the zygomatic. Upper incisors, without grooves, are rooted in the pterygoid bones posterior to the cheekteeth (Figure 104).

Cryptomys mole-rats are social, occurring in colonies with reproductive division of labour, overlap of generations, cooperative

Figure 104. Skull and mandible of *Cryptomys hottentotus* (BMNH 98.4.4.23).

care of young and high reproductive skew. All species studied to date are obligate outbreeders. In mesic areas, *Cryptomys* spp. are loosely social, whereas species in arid areas have well-developed social structures. Each colony is characterized by having a single reproductive ♀ and between one and two reproductive ♂♂. Non-reproductive animals exhibit socially induced infertility ranging from strict incest

avoidance in mesic species through to physiological suppression in arid species. In the clade (see below) containing *C. hottentotus*, courtship and copulation is usually initiated by ♂, whereas in the *C. damarensis* clade it is initiated by ♀. All species are subterranean and chisel-tooth diggers; they excavate extensive burrow systems by disposing of excavated soils as mounds on the surface.

Approximately 49 forms have been named (Ellerman 1940). Size, colour and external appearance are poor criteria for making comparisons between species in this genus. The genus *Cryptomys* is composed of two highly divergent clades, whose genetic distance can exceed that between some of the other genera in the family (Faulkes *et al.* 1997b), a division also supported by morphological characters of the skull. DNA sequence analysis has gone some way in clarifying the taxonomic problems of the genus (e.g. Allard & Honeycutt 1992, Faulkes *et al.* 1997b, Bennett & Faulkes 2000, Walton *et al.* 2000). The first clade contains all species except for *C. hottentotus*, has thick-walled infraorbital foramina and is distributed widely throughout savanna habitats in southern, central and eastern Africa, with two species with restricted distributions in West Africa. This clade is karyotypically very diverse (Burda *et al.* 1999), ranging from $2n = 40$ in *C. mehowi* to $2n = 74$ in *C. damarensis*. The second clade contains only *C. hottentotus*, has thin-walled elliptically shaped infraorbital foramina, and is karyotypically conserved ($2n = 54$).

The smallest genetic distance between *Cryptomys* species is 8.4% for *C. mehowi* and *C. bocagei*. *Cryptomys anelli* from Zambia and *C. darlingi* from Zimbabwe have traditionally been classified as subspecies

of *C. hottentotus*, but are highly divergent from this species and are indeed distinct species. Within the *C. hottentotus* clade, *C. h. nimrodi* from Zimbabwe, *C. h. natalensis* from South Africa (KwaZulu–Natal) and *C. h. pretoriae* from South Africa (Gauteng) are also genetically divergent from one another and should possibly be considered as separate species. There are no data for the genetic relationships between *C. foxi*, *C. zechi* and *C. ochraceocinereus*; all three species have a small thick-walled infraorbital foramina, as in *C. damarensis*.

These differences within *Cryptomys* have shown that the genus, as currently defined, may be composed of two genera. The genus *Fukomys* has been proposed (Kock *et al.* 2006) to contain all species (*anselli*, *bocagei*, *damarensis*, *darlingi*, *foxi*, *kafuensis*, *mehowi*, *ochraceocinereus*, *zechi*) except for *hottentotus*, which remains in the genus *Cryptomys*. *Fukomys* cannot be separated from *Cryptomys* on the grounds of morphological or morphometric characters. *Fukomys* is distinguished from *Cryptomys* by nuclear and mitochondrial DNA (Faulkes *et al.* 2004, Ingram *et al.* 2004) and high karyotypic diversity with diploid karyotypes ranging from $2n = 40$ to 80, as opposed to a very conservative $2n = 54$ in *Cryptomys* (van Daele *et al.* 2004, Deuve *et al.* 2008). The separation into two genera is supported by reciprocal monophyly of the two lineages based on nuclear and mitochondrial data sets and the level of sequence divergence observed between the two lineages for nuclear and mitochondrial DNA (e.g. *Bathyergus* and *Georchus*) (Faulkes *et al.* 1997b, Ingram *et al.* 2004).

Nigel C. Bennett

Cryptomys anelli ANSELL'S MOLE-RAT

Fr. Rat-taupe d'Ansell; Ger. Ansell's Graumull

Cryptomys anelli Burda, Zima, Scharff, Macholan and Kawalika, 1999. Z. Säugetierkunde 64: 36–50. Chainama Hills, Lusaka, Zambia.

Taxonomy Prior to 1999, this species was included in *C. hottentotus* (e.g. Ansell 1978). It was referred to as *C. hottentotus* or *Cryptomys* 'population Lusaka, karyotype $2n = 68$ ' in papers published between 1987 and 1999. This species has been placed in the genus *Fukomys* by Kock *et al.* (2006) (see genus *Cryptomys*). Synonyms: none. Allozyme profile (Filippucci *et al.* 1994, 1997) and DNA sequences (Ingram *et al.* 2004) clearly separate this species from other species of *Cryptomys*. Chromosome number: $2n = 68$, FN = 79–82 (Burda *et al.* 1999).

Description Medium-sized mole-rat. Pelage colour is age- and weight-dependent: dark slate-grey (neonates), greyish-brown (weaned young), brown (juveniles and subadults) and golden-ochre (adult animals). Head with conspicuous white patch on forehead in most (but not in all) individuals. Tail very short (ca. 14% HB). Skull: infraorbital foramina elliptical, wide at base, thick-walled. Upper incisors ungrooved. Nipples: $2 + 1 = 6$.

Geographic Variation None recorded.

Similar Species

Cryptomys kafuensis. Similar in appearance, head spot white, usually larger; chromosome number $2n = 58$.

Cryptomys anelli

Distribution Endemic to Africa. Zambezan Woodland BZ. Recorded only from several localities in C Zambia (Lusaka and its surroundings, to a maximum of ca. 100 km from Lusaka, but not across the Kafue R.).

Habitat Savanna bushland, cultivated fields, gardens and golf courses where mean annual rainfall is ca. 820 mm.

Abundance Detailed assessment of abundance not available, but the species appears to be rather abundant in the Lusaka and Central Provinces.

Adaptations Subterranean. Ansell's Mole-rat has a low resting metabolic rate of 0.63 ± 0.06 ml O₂/g/h (67% of expected). Has a low body temperature of 33.8 °C and a high thermal conductance of 0.12 ml O₂/h/ °C (Bennett *et al.* 1994a).

Foraging and Food Herbivorous; feeds on rootstocks, tubers, bulbs, corms and rhizomes (Scharff 1998).

Social and Reproductive Behaviour Social. Lives in family groups of about 12 animals (range 2–25, $n = 12$) (Scharff 1998). A colony consists of a founding reproductive pair and their offspring from several litters. These offspring do not reproduce due to incest avoidance based on individual recognition of the family members. Offspring are (in many cases probably lifelong) helpers at the nest (Burda 1995, Burda *et al.* 2000).

Reproduction and Population Structure Reproduction is aseasonal and one or two (rarely three) litters can be produced each year in captivity. Gestation: 98 (84–112) days. Litter-size: 2 (1–5), $n = 102$ litters. Sex ratio of neonates: 1 : 1.4 ($n = 159$). Weight of neonates: 7.9 (5.7–10.7) g. Pelage first visible on Day 8–10. Eyes open at weight 12.9 g on Day 23 (13–50). Solids first eaten ca. Day 22. Weaned at weight 34 g, on ca. Day 82 (75–105) (Burda 1989, 1990, Begall & Burda 1998). Non-reproductive ♀♀ have reduced

follicular development; tertiary follicles luteinize or atrophy so that ovulation does not occur (Willingstorfer *et al.* 1998).

Predators, Parasites and Diseases Apart from humans, no predators are known that have specialized on Ansell's Mole-rats. Ectoparasites have not been found. Low infestation with a nematode (*Protospirura muricola*) has been reported (Scharff 1998).

Conservation IUCN Category: Near Threatened.

Ansell's Mole Rats are considered to be agricultural and horticultural pests; they are hunted by local people and are a highly valued food.

Cryptomys bocagei BOCAGE'S MOLE-RAT

Fr. Rat-taupe de Bocage; Ger. Bocages Graumull

Cryptomys bocagei (de Winton, 1897). Ann. Mag. Nat. Hist., ser. 6, 20: 323. Hanha, Angola.

Taxonomy Originally described in the genus *Georchus*. Included within *C. hottentotus* by De Graaff (1981) and Smithers (1983), but now considered as a valid species by Woods (1993) and Woods & Kirkpatrick (2005). Recognized as a distinct species by Honeycutt *et al.* (1991) based on the character of the infraorbital foramina. This species has been placed in the genus *Fukomys* by Kock *et al.* (2006) (see genus *Cryptomys*). Synonyms: *kubangensis*. Subspecies: none. Chromosome number: $2n = 58$ (G. H. Aguilar unpubl.).

Description Medium-sized mole-rat with white patch on head. Dorsal and ventral pelage drab-grey to silvery-grey. Head blunt, usually with variably shaped white patch on forehead; incisor teeth visible outside lips. Long vibrissae. Eyes very small. External ear absent. Limbs short, feet pink and naked. Tail very short (ca.

7% of HB). Skull broad, strong; zygomatic arches slightly bowed anteriorly; infraorbital foramina small, teardrop-shaped (1.5–2 mm), thin-walled. Upper incisors ungrooved. Males slightly larger than ♀♀. Nipples: 2 + 1 = 6.

Geographic Variation None recorded.

Similar Species

Cryptomys mechowii. On average much larger in size.

Distribution Endemic to Africa. Zambezan Woodland BZ. Recorded in C and S Angola, N Namibia (particularly Ondjeva, Ongha and Ondongera in Ovamboland Province), extreme S DR Congo and W Zambia.

Habitat No information.

Abundance No information. Probably common.

Remarks Recorded to feed on geophytes (G. H. Aguilar unpubl.). Social behaviour: four animals were caught from one colony that was not completely trapped-out.

Conservation IUCN Category: Data Deficient.

Cryptomys damarensis DAMARALAND MOLE-RAT

Fr. Rat-taupe du Damara; Ger. Damaraland Graumull

Cryptomys damarensis (Ogilby, 1838). Proc. Zool. Soc. Lond. 1838: 5. Damaraland, Namibia.

Taxonomy Originally described in the genus *Bathyergus*. Included within *C. hottentotus* by Ellerman *et al.* (1953), De Graaff (1981) and Smithers (1983), but now considered as a valid species by Woods (1993) and Woods & Kirkpatrick (2005). Described as a distinct species by Honeycutt *et al.* (1991) on characters of the infraorbital foramina. Faulkes *et al.* (1997b) confirmed specific status by showing that an 11% sequence divergence in 12S rRNA occurred between haplotypes of *C. hottentotus* and *C. damarensis*. This species has been placed in the genus *Fukomys* by Kock *et al.* (2006) (see genus *Cryptomys*). Synonyms: *lugardi*, *micklei*, *ovamboensis*. Subspecies: none. Chromosome number: 2n = 74 or 2n = 78, aFN = 92 (Nevo *et al.* 1986).

Description Medium-sized colonial mole-rat with white patch on dorsal region of head. Pelage short, thick, with a sheen. Dorsal and ventral pelage fawn, or very dark brown to black. In a single colony, a single colour morph, or both colour morphs, may be present. Mid-dorsal and mid-ventral white stripes in some individuals. Isolated tactile hairs protrude from pelage, especially on the face. Head with large white patch on forehead, sometimes with flecks of pelage colour. Incisor teeth visible outside lips. Eye small. External ear

pinnae absent. Limbs short and feet pink and naked. Tail very short (ca. 18% of HB), with stiff bristles that radiate from tail. Skull: dorsoventrally flattened; sagittal crest well developed; zygomatic arch strongly bowed outwards; infraorbital foramina small, teardrop-shaped (1.5–2 mm), thin-walled; upper incisors ungrooved; angular process on mandible not extending far backwards. Nipples: 2 + 1 = 6.

Geographic Variation Individuals from South Africa (Kalahari), Botswana (Okavango swamps) and Zimbabwe are black in colour. Those from C Namibia (Dordabis and Rheoboth) may be either black or fawn in colour.

Similar Species

C. darlingi. On average smaller; pelage fawn (similar to the fawn-coloured morph of *C. damarensis*); chromosome number: 2n = 54; Zimbabwe and Mozambique.

C. hottentotus. On average smaller; pelage grey; chromosome number: 2n = 54; Western Cape, Northern Cape, Eastern Cape, KwaZulu–Natal, Free State, Gauteng and Mpumalanga Provinces. Occurs in sympatry with *C. hottentotus* in Van Zyl's Rus, Northern Cape Province.

*Cryptomys damarensis*

Distribution Endemic to Africa. Zambezi Woodland BZ and South-West Arid BZ (Kalahari Desert). Recorded from most of Botswana (except extreme east), NW South Africa, C and N Namibia, SW Zimbabwe and extreme W Zambia. Distribution closely associated with red Kalahari arenosols, but also occurs in coarse sandy soils.

Habitat Semi-arid thorn scrub, woodland savanna and grasslands associated with red Kalahari sands and sandy soils; rainfall is typically low and sporadic (200–400 mm/annum) and burrow temperatures range from a mean of 30 °C in summer to 19 °C in winter (Bennett *et al.* 1988).

Abundance Localized, but may be abundant in suitable habitats where population numbers can exceed 380 individuals/km². However, abundance of subterranean mammals is not easy to estimate.

Adaptations Subterranean. Activity is discontinuous throughout the day and night. Damaraland Mole-rats excavate extensive burrow systems that can extend for more than 1 km and appear to radiate from a central nest and nearby food store (Jarvis *et al.* 1998). The nest is deep, sometimes exceeding 2.4 m below the surface, and has two to three entrances. Toilet areas have not been found. Individuals within a colony remain resident in the same home-range for many years (>8 years; N. C. Bennett & J. U. M. Jarvis unpubl.).

When threatened, a Damaraland Mole-rat has a unique defensive posture, rolling onto its back, exposing its belly, with the mouth agape and incisors bared. It braces itself with its limbs and rolls from side to side (Bennett 1990). Like other species of *Cryptomys*, it can also throw its head back with mouth agape and produce a threatening grunt.

Damaraland Mole-rats have one of the lowest resting metabolic rates of all mammalian species: 0.66 ± 0.07 ml O₂/g/h (85% of expected), a low body temperature (35.1 °C) and a low thermal conductance 0.065 ml O₂/g/h/ °C (Bennett *et al.* 1992).

Foraging and Food Herbivorous. Superficial foraging burrows are excavated as the animals search for underground storage organs of geophytes (bulbs, tubers and rootstocks). There is selective storage of geophytes: geophytes that are proportionately larger may possibly have a longer 'shelf life', or it may be more cost-effective to transport large geophytes to the store than small ones. Geophytes include various genera of Hyacinthaceae (e.g. *Dipcadi*, *Ledebouria*, *Ornithogalum*), Portulacaceae (e.g. *Talinum*) and Cucurbitaceae (e.g. *Acanthosicyos*), a number of which are toxic to livestock but not to mole-rats. Portable bulbs and corms are stored whereas the very large tubers (e.g. *Acanthosicyos*) are partly eaten *in situ*, and will often regenerate (Bennett & Faulkes 2000, Jarvis *et al.* 2000).

Social and Reproductive Behaviour Social. Lives in medium-sized colonies of around 12 animals (range 2–41) (Bennett & Jarvis 1988, Jarvis & Bennett 1993). The colony consists of a founding reproductive pair and their progeny from several litters; these younger individuals do not breed while in the natal colony. Sex ratios of captured colonies range from 0.8 to 2.1 in favour of ♂♂. Mean body mass of individuals in the colony may vary from 103 to 202 g in ♂♂ and 88 to 145 g in ♀♀ (n = 6 colonies, n = 107 individuals) depending upon the ages of the adult non-reproductive animals in the colony (Jacobs *et al.* 1990). The reproductive pair consists of the most dominant individuals; the non-reproductive ♂♂ are more dominant than non-reproductive ♀♀. The non-reproductive members of the colony can be placed into work-related groups based on body mass: there is a tendency for smaller (not necessarily younger) animals to perform more burrow maintenance than larger (but not necessarily older) animals. An oestrus ♀ solicits the ♂ prior to mating. Multiple mating occurs following a ritualized courtship of tail-to-tail chasing, vocalizations and head mounting by the reproductive ♀ (Bennett & Jarvis 1988).

Reproduction and Population Structure In most ♂♂, the testes are abdominal and the penis is contained in a penile sheath; in a reproductive ♂, the penis is usually visible beyond the sheath and the testes are often in inguinal pockets. Females have external labial flaps and an os-clitoris, that is only exposed during sexual activity, and is the same length as the penis of the ♂. A vaginal closure membrane is present in non-reproductive ♀♀. The reproductive ♀ can be identified by her open vagina and prominent nipples.

Reproduction is aseasonal, with up to three litters per annum. Ovulation is spontaneous. Gestation: 78–92 days (Bennett & Jarvis 1988). Litter-size: 3 (1–6), n = 8 litters. At birth, young weigh 8–9 g and are mobile. Pelage develops from Day 6. Solid foods first eaten ca. Day 6–8. Eyes open on Day 18. Weaned Day 28. Inter-sibling sparring begins at Day 18–25. Young do not disperse but join the natal colony (Bennett *et al.* 1991).

Non-reproductive ♂♂ have functional gonads but are oligospermic and occasionally azoospermic, although they have similar hormone profiles to the reproductive ♂ (Maswanganye *et al.* 1999). In contrast, the non-reproductive ♀♀ do not ovulate and show reduced follicular development with tertiary follicles luteinizing or atresing. The hormone profiles of non-reproductive ♀♀ have lower concentrations of oestrogen, progesterone and LH than the reproductive ♀ (Bennett *et al.* 1993, 1994c). Reproductive suppression is due to two components: a suppressive action from the

social environment, and incest avoidance in the form of obligatory out-breeding. Removal of a non-reproductive ♀ from the colony releases her suppression and her gonads become active. In a functional colony, the oldest non-reproductive animals are the primary dispersers; however, when either a reproductive ♂ or ♀ dies, the entire colony will fragment. In either instance, dispersal occurs after rain when the costs of digging are lowest (Bennett *et al.* 1996).

Predators, Parasites and Diseases The Damaraland Mole-rat is at particular risk from predation during mound formation. Mole-snakes *Pseudapsis cana* appear to detect such freshly turned soil. They seize a mole-rat from behind, constrict and kill it. Cobras *Naja nivea* also enter the open holes of mole-rat burrows. Dispersing animals are particularly vulnerable to owls and small carnivores such as jackals, mongooses, Caracals *Caracal caracal* and occasionally Brown Hyenas *Hyaena brunnea*. Damaraland Mole-rats have conspicuously few parasites; the predominant parasites are intestinal nematodes.

Conservation IUCN Category: Least Concern.

There is little conflict with agriculture (unlike some other species of mole-rats) because most of the habitat is arid.

Measurements

Cryptomys darlingi DARLING'S MOLE-RAT (MASHONA MOLE-RAT)

Fr. Rat-taupe de Darling; Ger. Darlings Graumull

Cryptomys darlingi (Thomas, 1895). Ann. Mag. Nat. Hist., ser. 6, 16: 239. Salisbury, Rhodesia (now Harare, Zimbabwe).

Taxonomy Originally described in the genus *Georchus*. Included within *C. hottentotus* by Ellerman *et al.* (1953), De Graaff (1981), Smithers (1983) and Woods (1993) but now considered as a valid species (Woods & Kirkpatrick 2005). This species has been placed in the genus *Fukomys* by Kock *et al.* (2006) (see genus *Cryptomys*). Synonyms: *beirae*, *nimrodi*, *zimbitiensis*. Subspecies: none. Chromosome number: 2n = 54, aFN = 80 (Aguilar 1993).

Description Medium-sized mole-rat with a longitudinal white stripe on ventral surface. Pelage short and thick. Dorsal and ventral pelage blackish, seal-brown, slate- or silvery-grey. White stripe or patch on ventral pelage; variable in width and length, may extend for length of body. Head blunt, sometimes with white patch on forehead; incisor teeth visible outside lips. Isolated tactile hairs protrude from pelage, especially on the face. Eye small. External ear absent. Fore- and hindfeet naked with soft pink skin. Tail very short (ca. 7% of HB), naked with coarse vibrissae. Pelage of juveniles is darker than in adults. Skull broad, braincase large and rounded; infraorbital foramina small, teardrop (1.5–2 mm), thin-walled; upper incisors ungrooved. Nipples: 2 + 1 = 6.

Geographic Variation None recorded.

Similar Species

Cryptomys damarensis. Fawn-coloured morph very similar; on average larger; pelage fawn, or very dark brown to black; chromosome

number: 2n = 74; South Africa, Namibia, Zimbabwe, Botswana and Zambia.

Cryptomys darlingi

Distribution Endemic to Africa. Zambezian Woodland BZ. Recorded only in N and E Zimbabwe, extending into C Mozambique. Mainly restricted to the Mashonaland plateau at altitudes above 1000 m. Limits of geographic range not known.

Habitat Miombo woodland predominated by *Brachystegia* and *Julbernardia*. Also found in valley grasslands, and on sandstone and granitic derived soils in areas of relatively high and predictable rainfall (ca. 700 mm/annum) (Genelly 1965, as *C. hottentotus*).

Abundance Common in miombo woodlands and grasslands.

Adaptations Subterranean. Mashona Mole-rats have a low resting metabolic rate of 0.98 ± 0.14 ml O₂/g/h (97% of expected) and a low body temperature of 33.3 ± 0.5 °C. They have strong poikilothermic tendencies in body temperature below ambient temperatures of 25 °C, whereas above 25 °C they are endothermic (Bennett *et al* 1993a).

Foraging and Food Herbivorous. These Mole-rats sometimes burrow around the root systems of *Brachystegia* and *Julbernardia* trees, where they feed on geophytes and on the swollen roots of these trees (N. C. Bennett unpubl.).

Social and Reproductive Behaviour Social. Mashona Mole-rats live in small colonies of 5–9 individuals consisting of a founding reproductive pair and the offspring from several litters, who remain non-reproductive while resident in the natal burrow. Sex ratios of all individuals from captured colonies appear to be biased towards ♂♂. Mean body mass of all individuals in a colony varies from 52 to 75 g (n = 5 colonies), this depending upon number of adults in the colony. The reproductive animals are the most dominant, thereafter ♂♂ are more dominant than ♀♀ (Gabathuler *et al.* 1996). Non-reproductive members of the colony cannot be placed into clearly defined work-related groups based on body mass (cf. *C. damarensis*). When in oestrus, ♀ solicits ♂ prior to mating. Multiple copulations occur over two days (Bennett *et al.* 1994b). Reproductive inhibition in the non-breeding animals appears to be maintained by incest avoidance alone (Bennett *et al.* 1994b).

Reproduction and Population Structure Reproduction is aseasonal, with up to four litters per annum. Gestation (estimated): 56–61 days. Litter-size: 2 (1–3), n = 7 litters. Sex ratio at birth is parity. At birth, young weigh 6.9–8.2 g (n = 4). Pelage first appears Day 4. First solid foods eaten Day 14. Eyes open Day 14. Weaned ca. Day 45. Non-breeding ♂♂ are smaller than breeding ♂♂, the penis is enclosed by a sheath, and they lack prominent bulging inguinal testes. Non-reproductive ♀♀ have an imperforate vagina.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Cryptomys foxi Fox's MOLE-RAT

Fr. Rat-taupe de Fox; Ger. Foxs Graumull

Cryptomys foxi (Thomas, 1911). Ann. Mag. Nat. Hist., ser. 8, 7: 462. Panyam, Jos Plateau, Nigeria.

Taxonomy Originally described in the genus *Georychus*. De Graaff (1975) placed *foxi* as a subspecies of *C. ochraceocinereus*, an arrangement followed by Happold (1987). Currently considered as a valid species. Detailed analysis of skull characters provided by Williams *et al.* (1983). This species has been placed in the genus *Fukomys* by Kock *et al.* (2006) (see genus *Cryptomys*). Synonyms: none. Chromosome number: 2n = 66, FN = 122 (n = 6), 2n = 70, FN = 130 (Cameroon; Williams *et al.* 1983). See Rosevear (1969) for further information.

Description Sepia-coloured mole-rat, sometimes with whitish markings on head or body. Pelage soft and short, with velvet-like

texture. Dorsal and ventral pelage sepia-brown. Head blunt, usually with sub-circular white patch on forehead; incisor teeth visible outside lips. Long vibrissae. Eyes very small. External ear absent. Limbs short and feet naked. Fore- and hindfeet well-developed. Five digits on fore- and hindfeet. Tail very short (ca. 8% of HB), covered with stiff bristles. Skull: widest part of nasal bones anteriorly; upper incisors ungrooved and comparatively narrow (ca. 2.4 mm); infraorbital foramina teardrop-shaped (1.5–2 mm), thin-walled; upper cheekteeth comparatively short (mean 7.6 [range 7.2–8.3] mm). Individuals from Cameroon are larger than those from Nigeria (see Measurements). Nipples: 2 + 1 = 6.

Geographic Variation None recorded.

Similar Species

C. zechi. Pelage pale cinnamon; on average larger; widest part of nasal bones posteriorly; upper cheekteeth longer (ca. 8.3 mm); incisor teeth comparatively wider (ca. 3.2 mm); Ghana and Togo only.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ. Recorded only from near Panyam (1220 m) on the Jos Plateau, N Nigeria (Thomas 1911b, Rosevear 1969), and Ngaoundere, Cameroon (Williams *et al.* 1983). Occurs only at altitudes above 1000 m.

Habitat On the Jos Plateau, Nigeria (ca. 1000–1800 m), typical habitats are extensive grasslands, rocky areas and riverine forest along streams (Happold 1987).

Abundance Uncertain; very localized and probably uncommon.

Remarks Virtually nothing is known about this species. Subterranean, living in colonies. Twelve animals were trapped from one colony but it is not known whether these animals constituted the whole colony. The Rev. G. T. Fox, who collected the holotype, recorded that these mole-rats ate earthworms in captivity (Thomas 1911b), an unusual situation for members of a genus that is primarily vegetarian.

Conservation IUCN Category: Data Deficient.

Cryptomys hottentotus COMMON MOLE-RAT (HOTTENTOT MOLE-RAT)

Fr. Rat-taupe hottentot; Ger. Hottentotten-Graumull

Cryptomys hottentotus (Lesson, 1826). Voyage Monde Coquille, Zool. 1: 166. Paarl, Cape Province, South Africa.

Taxonomy Originally described in the genus *Bathyergus*. *Cryptomys hottentotus* is a geographically variable polytypic species (hence the many synonyms), and is in need of revision. Meester *et al.* (1986) refer to five subspecies (each with many synonyms): *hottentotus* (17 synonyms), *damarensis* (3), *darlingi* (3), *bocagei* (1) and *natalensis* (16). Corbet & Hill (1991) recognize *natalensis* as a valid species without comment. The taxa *damarensis*, *darlingi* and *bocagei* are currently regarded as three valid species and are placed in the same clade as *C. hottentotus* (see genus

profile), and *natalensis* is placed as a synonym of *C. hottentotus*. *Cryptomys hottentotus* is placed within its own clade within the genus (see genus profile). All the available evidence indicates that the *C. hottentotus* clade is chromosomally conserved ($2n = 54$), and is distributed throughout South Africa, extending into Mozambique and parts of Zimbabwe. Mitochondrial DNA sequence analysis consistently resolves six groups within the *C. hottentotus* clade as follows: *natalensis* (KwaZulu–Natal and Mpumalanga Provinces), *pretoriae* (Gauteng, North West and Limpopo

Provinces), *nimrodi* (SW Zimbabwe), *hottentotus* (Western Cape, Northern Cape and Eastern Cape Provinces), *mahali* (Gauteng Province) and *aberrans* (Eastern Cape Province) (Faulkes *et al.* unpubl.). The first four forms are considered as subspecies (see below), but the status of *mahali* and *aberrans* is uncertain (Faulkes *et al.* unpubl.) Synonyms: *aberrans*, *albus*, *amatus*, *arenius*, *beirae*, *bigalkei*, *caecutiens*, *cradockensis*, *darlingi*, *exenticus*, *holosericius*, *jamesoni*, *jorisseni*, *kopmotiensis*, *langi*, *lugwigii*, *mahali*, *melanoticus*, *montanus*, *natalensis*, *nemo*, *nimrodi*, *orangiae*, *pretoriae*, *rufulus*, *stellatus*, *talpoides*, *transvaalensis*, *valschensis*, *vandami*, *vrybergensis*, *whytei*, *zimbitiensis*, *zuluensis*. Subspecies: four. Chromosome number (*C. h. hottentotus*): $2n = 54$, $FN = 106$; (*C. h. natalensis*): $2n = 54$, $FN = 104$ (Nevo *et al.* 1986).

Description Medium-sized mole-rat with flattened body. Pelage short, thick and silky. Dorsal pelage cinnamon-buff, fawn or dark grey but with considerable geographical variation. Ventral pelage paler. Flanks may or may not be paler than dorsal pelage. Head similar in colour to body, with small white patch on forehead in some individuals. Isolated tactile hairs protrude through the pelage, more numerous on face than on body. Limbs short. Feet naked and pink. Tail very short (ca. 15% of HB), pink, with hairs fringing from the tail itself. Body size is variable, depending on habitat, status within the colony and reproductive state. Skull with strong convex curvature dorsally; sagittal crest poorly developed; infraorbital foramina elliptical (ca. 3 mm), thin-walled; upper incisors ungrooved; four cheekteeth without re-entrant folds and decreasing in size from P to M³. No (or very little) sexual dimorphism; sexes difficult to distinguish. Nipples: $2 + 1 = 6$.

Geographic Variation

- C. h. hottentotus*: Western, Eastern and Northern Cape Provinces and Free State of South Africa; $2n = 54$; pelage cinnamon-buff to fawn with or without head-patch.
- C. h. natalensis*: KwaZulu–Natal and Mpumalanga Provinces of South Africa; $2n = 54$; pelage dark grey to black with characteristic black colouration around snout (usually without distinct head-patch).
- C. h. pretoriae*: Gauteng, North West, Limpopo and Mpumalanga Provinces of South Africa; $2n = 54$; pelage silvery-fawn to grey, with or without head-patch.
- C. h. nimrodi*: Limpopo Province, South Africa, and S Zimbabwe; pelage silvery-fawn to cinnamon-buff, with or without head-patch.

Similar Species

- Bathyergus suillus*. HB much larger; pelage without sheen; skull much flatter with large sagittal and occipital ridges; forefeet with elongated claws; upper incisors grooved.
- B. janetta*. HB larger; dorsal pelage silvery-fawn with sheen; skull with smaller sagittal and occipital ridges; auditory bullae markedly swollen; palate extends posteriorly to level of M³; forefeet with elongated claws; upper incisors grooved.
- Georchus capensis*. On average larger; dorsal pelage russet; head blackish with white muzzle and large white patch around ear opening; forefeet without elongated claws; upper incisors ungrooved.

Distribution Endemic to Africa. Widespread in several BZs (South-West Cape BZ, South-West Arid Zone BZ [Karoo], Highveld

BZ, and parts of Coastal Forest Mosaic BZ). Recorded from South Africa, Lesotho, Swaziland and S Zimbabwe. In South Africa, known from Stellenbosch and Somerset West on the Cape Peninsula, north-west to Steinkopf and inland to Prieska and Calvinia (Northern Cape Province); also in consolidated sands of the east coast and throughout Eastern Cape Province and southern parts of Free State; and in grasslands and savanna woodlands of KwaZulu–Natal, Mpumalanga, North-West and Gauteng Provinces in a range of soils from granitic sandstones to coarse clays. In Zimbabwe, found in granitic sandstones and in brecciated soils.

Habitat Fynbos, grassland, savanna and Succulent and Nama Karoo with rainfall of 200–1000 mm per annum. Occurs in a range of substrates from friable sandy loams to exfoliated schists and sandy soils. Does not occur in heavy clay or very brecciated soils.

Abundance Uncertain. In preferred habitats, density may exceed 150/km². Abundance of subterranean mammals is not easy to estimate.

Adaptations Subterranean. Capable of running forwards and backwards with equal ease in the burrow (Bennett 1992). Common Mole-rats have a low resting metabolic rate 0.92 ± 0.1 ml O₂/g/h (90% of expected), low body temperature of 34.4°C and high thermal conductance of 0.14 ml O₂/g/h/°C (Bennett *et al.* 1992). Body size varies with environment: in arid habitats, the mean body size (mean weight ± 1 SE) is much lower (57.8 ± 0.7 g; $n = 722$) than in mesic habitats (75.2 ± 1.0 g; $n = 865$) (Spinks 1998, Spinks *et al.* 2000). This reduction in body size in arid environments may be an adaptation to burrowing and to dispersed food, which requires less soil to be excavated per metre of burrow (Bennett *et al.* 1992).

Foraging and Food Herbivorous. Common Mole-rats specialize on bulbs, corms and tubers, especially those of *Albuca*, *Lachenalia*,

Cryptomys hottentotus

Ornithogalum (Hyacinthaceae), *Romulea*, *Micranthus*, *Homeria* (Iridaceae) and *Oxalis* (Oxalidaceae). They select the larger-sized geophytes and place them in a store situated close to the nest. The stored geophytes are packed in soil and disbudded when they shoot. In areas with seasonal flooding, the store and nest are often sited in raised areas. In arid areas, where some geophytes are too large to carry to the store, they are left growing and hollowed out *in situ*; these partly eaten geophytes can often regenerate. Small quantities of above-ground vegetation may also be consumed. In mesic parts of their range, where food occurs in closely spaced clumps and rainfall is frequent, mole-rats are able to search for new resources for many months of the year. In arid regions, food is more dispersed and there are few opportunities to greatly extend the foraging burrows. A number of geophytes containing cardiac glycosides that are extremely toxic to livestock (e.g. *Ornithogalum* spp., *Homeria* spp., *Morea* spp.) are eaten by Common Mole-rats (Davies & Jarvis, 1986).

Social and Reproductive Behaviour Social. Lives in small colonies of around five animals (2–14, $n = 109$). A colony consists of a founding reproductive pair and number of non-reproductive offspring. Sex ratios of captured colonies ($n = 4$) ranged from 0.5 to 1.6. Sex ratio of a population is 1.28 : 1 in favour of ♂♂ ($n = 1053$). Reproductive animals are the dominant animals in the colony; of the non-reproductive animals, ♂♂ are more dominant than ♀♀. The non-reproductive members of the colony cannot be placed into clearly defined work-related groups based on body mass; there is, however, a tendency for smaller (not necessarily younger) animals to perform more burrow maintenance than their larger (not necessarily older) counterparts. Sexual differences are minimal and Common Mole-rats are difficult to sex. In ♂♂, the testes are abdominal and the penis is retracted into a penile sheath. A vaginal closure membrane is present in all ♀♀ that are not actively reproducing. In the reproductive ♀, the vagina is open, and axillary and inguinal nipples are prominent. The gonads of non-reproductive ♂♂ are active and incest avoidance prevents the non-reproductive ♂ offspring from breeding. The reproductive ♂ solicits the ♀ prior to mating. Multiple copulations occur between the pair following ritualized courtship by the ♂, who grasps the hind region of the ♀ with his incisors, sometimes also urinating on her head (Bennett 1989, Spinks 1998, Malherbe *et al.* 2003).

Common Mole-rats are strictly obligate outbreeders. A colony will remain resident in the same area for a number of years, and will aggressively defend its home-range against invasion by other colonies. In the more mesic parts of their distribution, there is some mixing of animals from different colonies, whereas in the arid parts, mixing rarely occurs (Bishop *et al.* 2004). Dispersal in the Common Mole-rat occurs more frequently in ♂♂ than in ♀♀.

Reproduction and Population Structure Reproduction is seasonal, occurring in summer (Oct–Jan), with up to two litters per annum. Litter-size: 3 (1–6), $n = 6$ (Bennett 1989, Bennett & Faulkes 2000). However, there is no regression of gonads in winter, perhaps because this is when adult non-reproductive animals can disperse and find mates. Elevated levels of reproductive hormones (testosterone, progesterone and oestrogen) at this time would promote bonding, and prepare a new reproductive pair for breeding during the following summer. Ovulation is induced (Spinks *et al.*

1999). Gestation: 59–66 days (Bennett 1989, Malherbe *et al.* 2003). At birth, young weigh 8–9 g and are altricial. Pelage developed from Day 8. First solid foods eaten ca. Day 10. Eyes open on Day 13. Weaned at Day 28. Inter-sibling sparring begins on Day 10–14. Young do not disperse but remain in the natal colony (Bennett 1989).

Predators, Parasites and Diseases Common Mole-rats are at particular risk to predation during mound formation. They are eaten by a wide range of predators, including Mole-snakes *Pseudapsis cana*, Shield-nosed Snakes *Aspidelaps scutatus*, Cobras *Naja naja*, Barn Owls *Tyto alba*, Marsh Owls *Asio capensis*, Grey Herons *Ardea cinerea* and a number of small carnivores. Ectoparasites include eight species of fleas (one of which, *Cryptopsylla ingrami*, is specific to this mole-rat), one species of tick, one species of louse and ten species of mites (De Graaff 1981).

Conservation IUCN Category: Least Concern.

In parts of its range, Common Mole-rats are agricultural pests.

Cryptomys kafuensis KAFUE MOLE-RAT

Fr. Rat-taupe du Kafue; Ger. Kafue Graumull

Cryptomys kafuensis Burda, Zima, Scharff, Macholan and Kawalika, 1999. Z. Säugetierkunde 64: 36–50. 'Hot Springs' in Itezhi-Tezhi, Kafue National Park, Zambia.

Taxonomy Prior to 1999, this species was included in *C. hottentotus* (e.g. Ansell 1978). Allozyme profile (Filippucci *et al.* 1994, 1997), chromosome number (Burda *et al.* 1999) and DNA sequences (Ingram *et al.* 2004) clearly separate this species from other species of *Cryptomys*. This species has been placed in the genus *Fukomys* by Kock *et al.* (2006) (see genus *Cryptomys*). Synonyms: none. Chromosome number: 2n = 58, FN = 82 (Burda *et al.* 1999).

Description Medium-sized mole-rat. Pelage dark slate-grey (young) to golden-ochre (adults). Head blunt with conspicuous white patch on forehead (in most but not in all individuals), variable in shape. Tail very short (15% of HB). Skull: infraorbital foramina elliptical, thin-walled; upper incisors ungrooved. Nipples: 2 + 1 = 6.

Geographic Variation None recorded.

Similar Species

C. anselli. Similar in appearance; white patch on the head tends to be smaller; chromosome number: 2n = 68.

Distribution Endemic to Africa Zambebian Woodland BZ. Recorded only in Itezhi-Tezhi, Southern Province, Zambia. (Degree square of 1526C of Ansell 1978.)

Habitat Grasslands and cultivated fields near villages where mean annual rainfall is 787 mm.

Abundance Abundant in this restricted area.

Remarks Little is recorded about the biology of this species. Subterranean and social. In many aspects of ecology, reproductive biology and behaviour apparently similar to *C. anselli*. Apart from humans (mole-rats are considered agricultural pests and are hunted for food), no predators are known to specialize on Kafue Mole-rats. Ectoparasites have not been found on this species. Endoparasites include two species of cestodes (*Inermicapsifer madagascariensis* and an undetermined species) and a nematode (*Protospirura muricola*); in one study, proportion of individuals with endoparasites was low (three out of 18) (Scharff *et al.* 1997).

Conservation IUCN Category: Vulnerable.

Cryptomys kafuensis

Cryptomys mechowii GIANT MOLE-RAT

Fr. Rat-taupe géant; Ger. Riesiger Graumull

Cryptomys mechowii (Peters, 1881). Senckenberg. Ges. Naturw. Freunde Berlin, p. 133. Malanje, North Angola.

Taxonomy Originally described in the genus *Georychus*. Recently placed in the genus *Fukomys* by Kock *et al.* (2006) (see genus *Cryptomys*). Synonyms: *ansorgi*, *blainei*, *mellandi*. Subspecies: none. Chromosome number: $2n = 40$, $FN = 80$ (Macholan *et al.* 1993).

Description Large, stout mole-rat, the heaviest of all species in the genus (but not as large and heavy as *Bathyergus* spp.). Pelage short and dense, almost woolly in texture. Pelage colour age- and weight-dependent: dark slate-grey (neonates), greyish-brown (weaned young), brown (juveniles and subadults) and golden-ochre (adult animals); hairs pale brown at base, variable as dorsal pelage at tip. Ventral pelage pale brown. Head large, without white spot on forehead (except very small spot in some individuals). Eyes small. No external ears (small ears hidden in pelage in specimens from Mt Moko). Mouth rusty-stained (some individuals). Fore- and hindfeet large and broad, naked with fringe of whitish bristles on outer border of each foot. Tail very short (up to 15 mm); longish white bristles, which extend beyond end of tail. Males on average larger than ♀♀. Skull: robust and dorsoventrally flattened; infraorbital foramina elliptical (ca. 5 mm), thin-walled and slender; upper incisors ungrooved, large and broad. Nipples: $2 + 1 = 6$.

Geographic Variation Individuals from Mt Moko, Angola are larger than those from elsewhere (see below).

Similar Species Several sympatric species; none are usually as large or weigh as much as *C. mechowii*.

Distribution Endemic to Africa. Zambezian BZ and Southern Rainforest–Savanna Mosaic. Recorded from N Zambia, S and E DR Congo, E Angola (and perhaps N Malawi).

Habitat Savanna bushland, cultivated and abandoned fields, gardens, dambos (temporary swamps), pine plantations and dense *Acacia* woodland. Found in a variety of soil types from quite stony to pure sand and clay. The area of distribution is characterized by an annual rainfall of more than 1100 mm (Scharff *et al.* 2001a).

Abundance Detailed assessment of abundance not available, but appears to be rather abundant in the Copperbelt Province of Zambia.

Adaptations Subterranean. Extensive burrow system comprises a deep nest (60–160 cm deep) with three or four entrances, food stores and toilet areas (Scharff *et al.* 2001a). Giant Mole-rats have a low resting metabolic rate 0.6 ± 0.08 ml O_2 /g/h (96% of expected), low body temperature of $34 \pm 0.4^\circ\text{C}$, and a low thermal conductance 0.09 ± 0.01 ml O_2 /g/h/ $^\circ\text{C}$ (Bennett *et al.* 1994a).

Foraging and Food Predominantly herbivorous. Food in non-cultivated areas includes grass rhizomes, roots, bulbs and tubers of diverse weeds, shrubs and trees; in cultivated areas, they probably

*Cryptomys mechowii*

feed on crop plants such as sweet potatoes, cassava and groundnuts (Scharff *et al.* 2001a). Giant Mole-rats are unusual amongst bathyergids, because they apparently supplement their diet with invertebrate and vertebrate commensals found in their burrows (Burda & Kawalika 1993, Scharff *et al.* 2001a).

Social and Reproductive Behaviour Social. Lives in colonies of 2–20+ (probably up to 40 or more) individuals (Burda & Kawalika 1993, Scharff *et al.* 2001a). Sex ratio within colonies is in favour of ♀♀ (Scharff *et al.* 2001a). The colony consists of a founding reproductive pair and non-reproductive offspring from several litters (Burda & Kawalika 1993, Wallace & Bennett 1998, Scharff *et al.* 2001a). The reproductive animals are the most dominant, and the non-reproductive ♂♂ are more dominant than ♀♀. The non-reproductive members of the colony cannot be placed into clearly defined work-related groups based on body mass (Wallace & Bennett 1998). Giant Mole-rats are very vocal compared to other species of *Cryptomys* (Burda & Kawalika 1993, Credner *et al.* 1997).

Reproduction and Population Structure Giant Mole-rats breed aseasonally both in the laboratory and in the field, producing up to three litters per annum (Burda & Kawalika 1993, Bennett & Aguilar 1995, Scharff *et al.* 1999). Gestation: 112 (89–118) days. Litter-size: 2.6 (1–5), $n = 41$. Sex ratio (mean of 41 litters) at birth biased in favour of ♀♀ (1 : 1.9). At birth, young weigh 19.6 (12.6–27.7) g. Thin pelage appears within the first week. Eyes open on Day 6. First solid foods eaten ca. Day 14. Weaned ca. Day 90. Inter-sibling sparring begins at Day 10 (Bennett & Aguilar 1995, Scharff *et al.*

1999). Growth is comparatively slow: weight increases in an almost linear fashion until ca. 120 g at age ca. Day 170; thereafter increase in weight continues until ca. 250–300 g at ca. Day 450 (n = 1; Scharff *et al.* 1999).

A colony consists of a founding reproductive pair and several litters of their offspring. In the laboratory, genetic studies have shown that female offspring may sometimes mate with the reproductive ♂ (M. J. O'Riain & J. Bishop unpubl.). Offspring can be denoted as (in many cases probably lifelong) helpers at the nest (Burda & Kawalika 1993, Bennett & Aguilar 1995, Scharff *et al.* 1999, 2001a, Burda *et al.* 2000).

Predators, Parasites and Diseases Giant Mole-rats are eaten by Mole-snakes and other large snakes, and also by humans. Ectoparasites have not been found on animals or in the nests of Giant Mole-rats. Endoparasites include three species of cestodes (*Inermicapsifer madagascariensis*, *Raillietina* sp., *Inermicapsifer madagascariensis*) and two species of nematodes (*Protospirura muricola*, *Cappilaria* sp.). Proportion of individuals with endoparasites is relatively low (12 out of 35) compared to most other rodents (Scharff *et al.* 1997, Scharff *et al.* 2001a).

Conservation IUCN Category: Least Concern.

Giant Mole-rats are detrimental to agriculture and horticulture and are considered as pests. They are an important source of protein for local people and their meat is highly valued in some areas of Zambia.

Cryptomys ochraceocinereus OCHRE MOLE-RAT

Fr. Rat-taupe ocre; Ger. Ockerfarbiger Graumull

Cryptomys ochraceocinereus (Heuglin, 1864). Nova Acta Acad. Caes. Leop., Dresden 31: 3. Upper Bahr-el-Ghazal, Sudan.

Taxonomy Originally described in the genus *Georychus*. Recently placed in the genus *Fukomys* by Kock *et al.* (2006) (see genus *Cryptomys*). Synonyms: *kummi*, *lechei*. Subspecies: none recognized here (but see Geographic Variation). Chromosome number: not known.

Description Medium-sized mole-rat. Pelage short, dense and soft. Dorsal pelage medium-brown, sometimes with silvery tinge. Ventral pelage similar in colour to dorsal pelage. Conspicuous roundish white head-spot (5–15 mm diameter) on forehead in some individuals, although absent in others (e.g. in parts of Uganda). Eyes blue. Conspicuous white eye-ring. Fore- and hindfeet small, broad and naked. Forefoot with five digits, hindfoot with five digits; all with sharp claws. Small fringe of pale white hairs around base of hindfoot. Tail (ca. 10% of HB) barely visible, mostly obscured by hair-like bristles. Skull: infraorbital foramina round-oval (ca. 2 mm diam.), thick-walled; upper incisors ungrooved. Nipples: 1 + 1 = 4.

Geographic Variation De Graaff (1975) records two subspecies: *C. o. ochraceocinereus* from Upper Bahr el Ghazal, Sudan, and *C. o. oweni* from S Sudan.

Distribution Endemic to Africa. Primarily Northern Rainforest–Savanna Mosaic of central Africa. Recorded from S Sudan, N Uganda, N DR Congo and Central African Republic. Locality records are widely distributed. Presence in W Cameroon and NW Kenya (as shown on map) is uncertain.

Habitat Wooded savanna (e.g. *Isberlinia* woodlands) and cultivated land.

Abundance Uncertain; widespread but localized. In Didinga Hills, S Sudan, recorded as 'Plentiful in mountain-meadows' (Setzer 1956).

*Cryptomys ochraceocinereus*

Remarks Subterranean. The burrow is a network of tunnel passages, which may attain an overall length of 315 m with up to 32 mounds of excavated soil. The mounds are irregularly placed and in

groups of three or four close together. An enlarged area in a passage forms the nest, which is lined with grasses on the outside and with roots of trees and leaves on the inside (Verheyen & Verschuren 1966). Mounds are 7–10 cm high and 20–25 cm at the base (Hatt 1940a). Herbivorous. In Garamba N. P. (NE DR Congo) feeds on roots, principally on those of *Dioscorea abyssinica* (Verheyen & Verschuren 1966, as *C. lechei*).

Conservation IUCN Category: Least Concern.

Cryptomys zechi TOGO MOLE-RAT

Fr. Rat-taupe du Togo; Ger. Togo Graumull

Cryptomys zechi (Matschie, 1900). Sber. Ges. naturf Freunde, Berlin, p. 146. Near Kete Krachi, Middle Volta, Togo. (Old Kete Krachi, now inundated by L. Volta, is in present-day Ghana, not Togo [Grubb *et al.* 1998]).

Taxonomy Originally described in the genus *Georychus*. Recently placed in the genus *Fukomys* by Kock *et al.* (2006) (see genus *Cryptomys*). Synonyms: none. Chromosome number: not known. See Rosevear (1969) for further information.

Description Pale-coloured mole-rat, sometimes with whitish markings on head or body. Pelage soft and short, with velvet-like texture. Dorsal pelage pale cinnamon to buff (and slightly variable); hairs unicoloured, may be white very close to base. Ventral pelage not recorded. Head blunt, usually with white patch on forehead; incisor teeth visible outside lips. Long vibrissae. Eyes very small. External ear absent. Limbs short. Fore- and hindfeet well-developed and naked. Five digits on fore- and hindfeet. Tail very short (ca. 8% of HB), covered with stiff bristles. Skull: widest part of nasal bones posteriorly; infraorbital foramina round-oval (ca 2 mm diam.), thick-walled; upper incisors ungrooved and comparatively wide (ca. 3.2 mm). Nipples: 2 + 1 = 6.

Geographic Variation None recorded.

Similar Species

C. foxi. On average smaller; pelage dark sepia-brown; widest part of nasal bones anteriorly; P⁴–M³ shorter (ca. 7.6 mm); incisor teeth comparatively narrow (ca. 2.4 mm). Nigeria only.

*Cryptomys zechi*

Distribution Endemic to Africa. Guinea Savanna BZ. Recorded from NW Ghana and between the Oti and Volta rivers in Togo. One specimen (BMNH) allocated to this species from SW Sudan (Rosevear 1969) is probably *C. ochraceocinereus* (Grubb *et al.* 1998).

Habitat Grasslands with a few scattered trees (typically *Khaya senegalensis*, *Butyrospermum parkii*, *Adansonia digitata*, *Parkia clappertoniana* and *Ceiba pentandra*) (Yeboah & Dakwa 2002).

Abundance Unknown; presumably rare with a rather restricted distribution.

Remarks Colony size 1–7 (average four animals). Sex ratio of colony members is parity. It is believed that animals occur in small colonies comprising a reproductive pair and their litter. Reproduction restricted to the reproductive pair (Yeboah & Dakwa 2002).

Conservation IUCN Category: Least Concern.

GENUS *Georychus*

Cape Mole-rat

Georychus Illiger, 1811. Prodr. Syst. Mamm. Avium., p. 87. Type species: *Mus capensis* Pallas, 1778.

Georychus capensis.

A monotypic genus with a restricted distribution in South Africa. The genus occurs from the Cape Peninsula of Cape Province eastwards through Eastern Cape Province to KwaZulu–Natal and Mpumalanga Provinces. Preferred habitat is loose sandy soils and loams in mesic regions of South Africa, usually where mean annual rainfall is >500 mm.

Georychus mole-rats are of intermediate size, being larger than most species of *Cryptomys* but smaller than *Bathyergus*. The pelage is distinctive: head black with flat white muzzle, white lips and eye-ring; and large white patch around auditory meatus. Dorsal pelage of body varies from dark grey, russet to orange-cinnamon; ventral pelage whitish. Digits of fore- and hindfeet are short, with short claws. Tail is short and white. The skull is less robust than in *Bathyergus* and is characterized by upper incisors without grooves, which have their roots in the pterygoid bones behind the cheekteeth. Each upper cheektooth has one narrow inner and one outer fold that persist in adults (the only genus without simplified ovate cheekteeth in adults). The jugal bone dovetails into a backward projection of the zygomatic arch (Figure 105). Other characters of the genus are given in the species profile. The single species is *Georychus capensis*.

Figure 105. Skull and mandible of *Georychus capensis* (BMNH 95.9.3.18).

Nigel C. Bennett

Georychus capensis CAPE MOLE-RAT (BLES MOL)

Fr. Rat-taupe du Cap; Ger. Kap-Blessmulle

Georychus capensis (Pallas, 1778). Nova. Spec. Quad. Glir. Ord., 76: 172. Cape of Good Hope, South Africa.

Taxonomy Originally described in the genus *Mus*, but later placed in *Marmota* (see de Graff 1981). In 1811, Illiger proposed the genus *Georychus* with *Mus capensis* as the type. In 1832, Smuts referred to the species as *Bathyergus capensis*. Modern authors, e.g. De Graaff (1981) and Smithers (1983), refer to the species as *Georychus capensis*. The populations from Western Cape Province and from KwaZulu–Natal could represent two different species as allozyme and mitochondrial DNA RFLP analyses suggest they are divergent (Honeycutt *et al.* 1987; Nevo *et al.* 1987). Synonyms: *buffonii*, *canescens*, *leucops*, *yatesi*. Subspecies: none. Chromosome number: $2n = 54$, $aFN = 100$ (Taylor *et al.* 1985, Nevo *et al.* 1986).

Description Medium-sized mole-rat with distinctive black and white colouration on head. Pelage thick and woolly. Dorsal pelage russet, often with a brownish tinge. Ventral pelage silvery-white. Unlike other genera, tactile hairs do not project from the pelage on the body. Head large and blunt, black, charcoal or deep russet, with a pattern of white markings unlike that of any other mole-rat. Muzzle and lips white. Eyes black (a little larger than other bathyergids) with large white eye-ring. Large white patch around auditory meatus. Fore- and hindfeet usually white. Tail very short (ca. 13% of HB), pink with a number of coarse white hairs radiating from it. Skull: dorsoventrally flattened; old animals possess distinctive sagittal and nuchal crests; jugal dovetails into backward projection of the zygomatic arch; infraorbital foramina small, round (ca. 1–1.5 mm), thick-walled. Upper cheekteeth each with one narrow inner and outer fold that persist in adults. Upper incisors ungrooved. No sexual dimorphism. Nipples $2 + 1 = 6$.

Geographic Variation None except for some genetic characters.

Similar Species

Bathyergus suillus. Larger; pelage cinnamon-brown, and sometimes with darker mid-dorsal band; forefeet with elongated claws; upper incisors with grooves.

Cryptomys hottentotus. On average much smaller; pelage fawn to grey.

Distribution Endemic to Africa. South-West Cape BZ and some parts of the Highveld BZ. Recorded only from South Africa; distribution is disjunct in mesic regions where mean annual rainfall is >500 mm. Recorded from Cape Peninsula in SW Western Cape Province northwards to Citrusdal and Nieuwoudtville, and eastwards to Port Elizabeth and W Eastern Cape Province (formerly Transkei). Isolated populations occur in KwaZulu–Natal Province near the border with Lesotho, and at Belfast, Wakkerstroom and Ermelo in Mpumalanga Province (formerly Eastern Transvaal). In S Western Cape Province, found at 12–510 m and in KwaZulu–Natal at 1372–1700 m.

Habitat Coastal and montane fynbos, forest and savanna grassland, where mean annual rainfall is 500–800 mm. Occurs in sandy loams, alluvium and clay soils. In coastal regions, occurs where annual rainfall

*Georychus capensis*

is 279–728 mm (mean ca. 500 mm) and in KwaZulu–Natal where annual rainfall is 954–1278 mm (mean ca. 800 mm). Sympatric with *Bathyergus suillus* and *Cryptomys hottentotus* in coastal areas where the sands are more consolidated.

Abundance Uncommon and localized, but densities may exceed 30 animals/km² in Cape Town.

Adaptations Strictly solitary and highly territorial. Multiple occupancy of burrows only during the breeding season, when the mate is present or when ♀ has young. Territorial drumming, using both hindfeet simultaneously, is frequently performed to advertise presence in the burrow system. The burrow system can exceed 130 m in length, and the burrow diameter is typically 100 mm. The burrow system comprises a central nest, a food store and a toilet area located away from the nest area. The food store consists of geophytes packed with soil; stored geophytes are disbudded when they sprout. Mounds are thrown up after rain when the soil is moist. Cape Mole-rats have been observed above ground on occasions, particularly after dusk. It is thought that in mountainous regions, where there are pockets of soil interspersed with rocky barriers, they disperse above ground.

Cape Mole-rats have a low basal metabolic rate of 0.59 ml O₂/g/h, and low body temperature (36°C).

Foraging and Food Herbivorous. Food is located as the mole-rats excavate their superficial (5–25 mm deep) foraging tunnels of diameter 7–8 cm. Most extensions to the burrows occur after rainfall when the costs of burrowing are lowest. The diet consists predominantly

of geophytes – bulbs, corms and tubers – but also ca. 6% above-ground vegetation. The geophytes include species of Hyacinthaceae (e.g. *Albuca*, *Lachenalia* and *Ornithogalum*), Iridaceae (e.g. *Romulea*, *Micranthus* and *Homeria*) and Oxalidaceae (e.g. *Oxalis*). A number of these contain cardiac glycosides and are toxic to livestock but not to mole-rats. Cape Mole-rats selectively store the larger-sized geophytes of many species, and food stores may exceed 5000 items. The food in the store is probably eaten when ♀ has young or during unfavourable periods when soils are difficult to excavate (Lovegrove & Jarvis 1986).

Social and Reproductive Behaviour Solitary, aggressive and territorial. Seismic signalling (which differs from territorial drumming) occurs at the onset of reproduction. Males and ♀ ♀ drum at different frequencies. The onset of courtship seismic signalling in ♂♂ is accompanied by raised urinary testosterone concentrations, and enlargement of the testes and accessory reproductive glands. Hindfoot seismic signalling by ♂♂ is extremely fast, each drum pulse in ♂♂ lasting two minutes with a beat length of 0.035 seconds. Females do not drum as fast, with a beat length of 0.05 per second. Courtship is usually initiated by ♂ and copulation is brief, involving multiple intromissions of 2–3 thrusts per second, interspersed by short periods during which the animals are involved in bouts of grooming, particularly around the genitalia (Bennett & Jarvis 1988, Narins *et al.* 1992).

Reproduction and Population Structure Reproduction is seasonal; young are born in summer (Aug–Dec), and ♀ produces a maximum of two litters/summer. Gestation: ca. 44 days. Litter-size: 6 (3–10), *n* = 19. At birth, young naked and blind. Pelage with the distinctive markings Day 7. Eyes open Day 9. First solid foods eaten ca. Day 17. Weaned Day 28. Pup development is comparatively rapid compared with that of social species. Inter-sibling aggression begins around Day 35, and young disperse (either below or above ground) at about Day 50.

Predators, Parasites and Diseases Cape Mole-rats are particularly vulnerable to predation during mound formation and

when moving above ground. Preyed upon by Mole-snakes *Pseudapsis cana*, cobras, owls, herons and small carnivores. Few parasites are associated with these mole-rats: ectoparasites includes four species of mites, a tick and a flea; endoparasites include a tapeworm (*Echinococcus* sp.) and a nematode (*Trichurus* sp.). Mole-rats are susceptible to bubonic plague (De Graaff 1981).

Conservation IUCN Category: Least Concern.

Cape Mole-rats are occasionally an agricultural pest, and can cause problems for horticulturists and green-keepers.

GENUS *Heliophobius*

Silvery Mole-rat

Heliophobius Peters, 1846. Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin 11: 259. Type species: *Heliophobius argenteocinereus* Peters, 1846.

Heliophobius argenteocinereus.

Currently considered to be a monotypic genus distributed from Kenya southwards through Tanzania to E DR Congo, N Zambia, Malawi and Mozambique north of the Zambezi R. Occurs in a variety of savannas and woodlands, and in many soil types from 'black cotton' soil (very sticky when wet, hard when dry) to well-drained sandy soils.

The genus is distinguished from other genera in the family by long, silky pelage, up to six simple upper and lower cheekteeth (not usually all present at the same time), and a narrow palate that does not extend posteriorly beyond the level of the cheekteeth. Cheekteeth show re-entrant folds in young animals. Unlike *Bathyergus*, and like the other genera of mole-rats, the angular process of the lower jaw does not extend far posteriorly to the skull (Figure 106).

Figure 106. Skull and mandible of *Heliophobius argenteocinereus* (HC 2438). Subadult: only three cheek-teeth visible (cf. 4–5 in adults).

Heliophobius argenteocinereus SILVERY MOLE-RAT

Fr. Rat fouisseur gris-argent; Ger. Silbergrauer Erdbohrer

Heliophobius argenteocinereus Peters, 1846. Bericht Verhandl. K. Preuss. Akad. Wiss. Berlin 11: 259. Tete, Mozambique. (See also below.)

Taxonomy Ellermann (1940) listed two species of *Heliophobius*: *H. argenteocinereus* and *H. spalax*, as well as eight subspecies of *H. argenteocinereus* (Honeycutt *et al.* 1991). All forms currently considered to be synonyms of *H. argenteocinereus*. However, genetic differences between animals from Kenya and from Malawi suggest that populations in different parts of the geographic range may be specifically or subspecifically different (see genus profile). Molecular studies suggest that there is a good case for recognizing five genetically divergent clades within the species: *robustus/mottoulei* species complex (clade 1), *H. kapiti* (clade 2a), *H. spalax* (tentatively clade 2b), *H. emini* (clade 3), *argenteocinereus/angonicus* complex (clade 4) and *H. marungensis* (clade 5) (C. Faulkes and N. Bennett, pers. comm.). Synonyms: *albifrons*, *angonicus*, *emini*, *kapiti*, *marungensis*, *mottoulei*, *pallidus*, *robustus*, *spalax*. Subspecies: none currently recognized (but see above and Geographic Variation). Chromosome number: $2n = 60$ (George 1979a), $2n = 62$ (Scharff *et al.* 2001b).

Description Medium-sized silvery-grey mole-rat with soft silvery pelage. Pelage silky and long (20–25 mm). Dorsal pelage silvery-grey to tan. Nose, eye region, lateral parts of head, limbs and ventral pelage paler. Head similar to dorsal pelage, paler around muzzle, eyes and nose; small white patch or fleck on forehead in some individuals (ca. 50% of those in Malawi, R. Sumner pers. comm.).

Biological characters of the genus include solitary behaviour, seasonal breeding, and a long gestation (87–101 days) that limits ♀♀ to having one litter a year (up to five young/litter). The other solitary genera (*Bathyergus*, *Georchus*) have shorter gestations that allow two litters in the breeding season after winter rainfall (late winter, early spring). *Heliophobius* has a wider geographic distribution than the other solitary genera (Jarvis & Bennett 1991, Sumner *et al.* 2003a).

Ellerman (1940) recognized two species, *H. argenteocinereus* and *H. spalax* (from Kilimanjaro, Tanzania) although Honeycutt *et al.* (1991) consider the genus to be monotypic with variations that are age-related. Recent studies have shown large genetic divergencies between animals from Kenya and from Malawi (up to 15.4% HKY85 corrected cytochrome *b* sequence differences; C. G. Faulkes pers. comm.). Furthermore, there are chromosomal differences between the Zambian populations ($2n = 62$, Scharff *et al.* 2001b) and those in Kenya ($2n = 60$, George 1979a). The systematics of this genus requires further study. The single species is *Heliophobius argenteocinereus*.

J. U. M. Jarvis

Incisor teeth long, slightly curved and lying outside the lips. Limbs short. Feet, pale-coloured, not enlarged, outer edges fringed with stiff hairs. Five digits, not strongly clawed. Tail very short (8–9% of HB), pale-coloured, with fringe of stiff hairs. Sexual dimorphism occurs in some regions (see below). Infraorbital foramen round (diam. 1.5 mm), thick-walled. Upper incisors ungrooved. (See also genus profile.) Nipples: $2 + 1 = 6$.

Geographic Variation Silvery Mole-rats from Malawi are larger than those recorded elsewhere; they also have shorter pelage (10–15 mm) and show sexual dimorphism with ♂♂ being about 15% larger than ♀♀ (Sumner *et al.* 2003a). Tail length is shorter than in specimens from Kenya, and ♀♀ have significantly longer tails (12.9 ± 1.8 mm) than the ♂♂ (12.4 ± 1.7) (R. Sumner pers. comm.). There is a white patch in the axilla of animals from Athi Plains, Kenya, but not from Malawi (J. Jarvis & R. Sumner unpubl.). The pelage is darker and the head-patch is larger in animals from Morogoro, Tanzania (C. Faulkes pers. comm.). Molecular genetic studies also show considerable geographic variation (see above).

Similar Species

Tachyoryctes splendens. Similar size; ear pinnae present, but small; eyes larger; incisors orange. (Although subterranean in habit, as are

*Heliophobius argenteocinereus*

bathyergid mole-rats, *Tachyoryctes splendens* belongs to a different family of rodents – Spalacidae: Tachyoryctinae.)

Distribution Widespread in Zambezian Woodland BZ and southern part of Somalia–Masai Bushland BZ. Recorded from C and S Kenya, Tanzania, Malawi, E Zambia, C and N Mozambique, and E DR Congo. Occurs from ca. 100 m to >2000 m and where annual rainfall is usually 250–900 mm, and up to 1500 mm (in Malawi). The type locality is given as Tete (which is on the southern (right) bank of the Zambezi R.); however, the type description records that the holotype (and specimens of other species) came from ‘Tette’ without saying precisely where they were caught. Smithers & Lobão Tello (1976) show that all records in Mozambique come from north of the Zambezi R., although Smithers (1983), which considers only Africa south of the Zambezi, shows a small range south of the Zambezi. As pointed out by Skinner & Smithers (1990), it seems unlikely that the species occurs south of the Zambezi.

Habitat *Combretum* and *Brachystegia* woodlands, rocky hillsides and sub-montane grasslands. In Malawi, frequently invades crops of banana, cassava and sweet potato (R. Sumbera pers. comm.). Occurs in a wide range of soils from well-drained easily worked sandy soils to heavy ‘cotton soils’ that are very hard when dry but sticky and waterlogged when wet (Kingdon 1974, Ansell & Dowsett 1988, J. U. M. Jarvis unpubl.).

Abundance Little information. Densities are low on the Athi Plains, Kenya (J. U. M. Jarvis unpubl.). In Malawi, density is 5.2/ha at Blantyre (Sumbera *et al.* 2003a, b). Sex ratio is parity (Sumbera *et al.* 2003a).

Adaptations Subterranean. Silvery Mole-rats dig using their chisel-like incisor teeth. On the Athi Plains, Kenya, foraging burrows are 12–23 mm below the surface, 50 mm in diameter and average

47 m (range 39–61, $n = 4$) in length (Jarvis & Sale 1971). In Malawi, mean burrow lengths are 73 m (range 22–138) at Blantyre, and 105 m (range 39–188) at Mulanje (Sumbera *et al.* 2003b, R. Sumbera unpubl.). Nest chambers are slightly deeper (300 mm) and contain a hollow ball of nesting material (grass, corm husks, skins of tubers); deeper still is a bolt-hole (up to 540 mm) where a mole-rat can retreat when threatened. Toilet areas are in blind-ending tunnels (Sumbera *et al.* 2003b). When the black cotton soil is wet, the animals use balls of mud to repair damaged burrows. Burrow systems often associated with slightly raised areas with better drainage (J. U. M. Jarvis unpubl.). Individuals show no particular activity pattern, and are active during the day and night (Jarvis 1973b).

Foraging and Food Herbivorous. Little known of the diet in the wild. In Kenya and Malawi, partly eaten tubers of *Dolichos* sp. and *Vigna* sp., still growing *in situ*, were apparently harvested as needed by the mole-rats (Jarvis & Sale 1971, R. Sumbera pers. comm.). Of the two tubers, *Vigna* is the preferred food and appears to be the key species determining the occurrence of Silvery Mole-rats near Blantyre (R. Sumbera pers. comm.). In Malawi, other species such as *Gladiolus dallenii*, *Imperata cylindrica* and *Hypoxis* sp., as well as a variety of cultivated root crops, have also been found in food stores (either in special chambers or blind-ending tunnels) (R. Sumbera pers. comm.). In captivity, animals are strongly selective, preferring bulbs and tubers, which they peel before eating. They practise coprophagy, seizing faecal pellets as they are voided from the anus with their incisors, and eating up to 12 pellets at one time (Jarvis 1969b).

Social and Reproductive Behaviour Silvery Mole-rats aggressively defend burrows against conspecifics. Animals emit a snorting hiss when cornered, assume a rigid stance with the feet braced and head thrown up, and with mouth and eyes wide open. When fighting, opponents lock incisors and sometimes roll over while still maintaining a grip on the opponent. Territorial drumming has not been reported (Jarvis 1969a, Sumbera *et al.* 2003a), but short, fast, repeated drumming with the forelimbs occurs during highly aggressive encounters (Sumbera 2001). In Kenya, animals are unusual amongst bathyergids in emitting an almost continuous cry (similar to a newborn baby) when alarmed (such as being transported by car; Jarvis 1969a). Silvery Mole-rats from Malawi are not very aggressive and will often coexist in captivity. Courtship behaviour (Sumbera 2001) is initiated by ♂, who follows ♀, sometimes sniffing her anogenital region. The animals face each other, gently nibble each other or lock incisors. Sometimes one of them (of either sex) lies on its back. Both animals vocalize, ♀ more so than ♂. The ♂ frequently urinates on vertical surfaces. Repeated intromissions (10–30) and rapid thrusting (7.3/sec) occur during copulation. Aggression has not been observed at the end of mating (Sumbera 2001).

Reproduction and Population Structure Reproduction is seasonal. In Malawi, mating occurs during the beginning of the cold dry season (Apr–Jun) and young are born when it is hot and dry (Aug–Oct) (Sumbera *et al.* 2003a), whereas limited data from Kenya indicate that young are born at the onset of the long rains (Apr–Jun) (Jarvis 1969a). Gestation: 87–101 days ($n = 3$ litters; Jarvis & Bennett 1991, Sumbera *et al.* 2003a). Litter-size: 3.2 (2–5), $n = 27$ litters (Sumbera *et al.* 2003a). At birth, mean weight of young 12.8 g

(n = 5). First solids eaten Day 8–11. Eyes open Day 13–14. Weaned ca. 2 months. Mean adult weight ca. 12 months. The ability to engage in serious sparring/fighting appears to be correlated with attainment of a specific body weight (and not with age), ranging from ten weeks (♂ WT: 94 g) to 22 weeks (♂ 80 g) (Sumbera *et al.* 2003a). The long gestation precludes the ability of ♀ to have more than one litter each breeding season. The lack of seismic signalling, ‘relatively high pacifism in captive animals’, capture of mature animals above ground, and no evidence of interlinking burrows suggest that this species may find its mates by moving above ground (Sumbera *et al.* 2003a).

Predators, Parasites and Diseases Little information available. However, predators are probably snakes, raptors and small carnivores. Endoparasites include four species of *Eimera* (Koudela *et al.* 2000, Modry *et al.* 2005), *Protospirura muricola* and *Inermicapsifer arvicanthidis* (Tenora *et al.* 2003). Ectoparasites include an unidentified species of mite (Trombiculidae, Acarina) (R. Sumbera unpubl.).

Conservation IUCN Category: Least Concern.

GENUS *Heterocephalus*

Naked Mole-rat

Heterocephalus Rüppell, 1842. Mus. Senckenbergianum Abh. 3 (2): 99. Type species: *Heterocephalus glaber* Rüppell, 1842.

Heterocephalus glaber.

Heterocephalus is a monotypic genus distributed only in NE Africa (parts of Kenya, Ethiopia and Somalia). The habitat is semi-desert where the annual rainfall is <400 mm, with long periods without rain, and where many species of plants have underground storage organs.

Heterocephalus is unique among the Bathyergidae (and indeed amongst adult rodents) in having no pelage. The skin is pink-brown and naked, with isolated sensory hairs, the tail is comparatively long, and Digit 3 of forefoot is longer than Digit 4. There are three cheekteeth in each ramus of the skull and mandible. Body weight is highly variable. Other characteristics of the genus are given in the species account.

The single species in the genus, as for other species in the family, is subterranean. Individuals live in colonies that have a very special social system that has been likened to the eusocial system of termites (for reviews, see Sherman *et al.* 1991, Bennett & Faulkes 2000, Jarvis & Sherman 2003). Because of the many unique characteristics of Naked Mole-rats, the genus has been placed in a subfamily of its own, Heterocephalinae, separate from all the other genera of the Bathyergidae (see Woods & Kirkpatrick 2005 and references therein). The single species is *Heterocephalus glaber*.

Heterocephalus glaber NAKED MOLE-RAT

Fr. Hétérocéphale glabre; Ger. Nacktmull

Heterocephalus glaber Rüppell, 1842. Mus. Senckenbergianum Abh. 3(2): 99. Shoa, Ethiopia.

Taxonomy Several species and subspecies have been described primarily based on body size, number of cheekteeth (two or three) and number of ribs (11 or 12 pairs), but *Heterocephalus* is currently considered to be monotypic (Honeycutt *et al.* 1991, Allard & Honeycutt 1992). However, mean genetic divergence between haplotypes from E Ethiopia and S Kenya is 10% for cytochrome *b* gene, a value exceeding interspecific differences in some other genera of mole-rats (Faulkes *et al.* 1997b, 2004). Captive animals from Lerata, N Kenya and Mtito Andei, S Kenya, have a genetic distance of 3% and are able to interbreed. Few samples from Ethiopia and Somalia are currently available for taxonomic study and nothing is known of their biology. Synonyms : *ansorgei*, *dunni*, *phillipsi*, *progreiens*, *scortecchi*, *stygius*. Subspecies: none. Chromosome number: $2n = 60$ (George 1979b).

Description Small mole-rat, the smallest species in the family, naked, without pelage and with a comparatively long tail. Skin loose, heavily creased, brownish-pink, darker dorsally than ventrally in

younger animals. Isolated pale-coloured tactile hairs all over body, especially on face and tail. Head large, cone-shaped, blunt anteriorly. Eyes tiny, eyelids thickened with minute eyelashes. Ears lack pinnae; external auditory meatus slightly raised. Limbs short and slender, tapering rapidly toward feet. Forefeet small and stubby, hindfeet longer and fringed on outer edge with stiff hairs; digits slender. All digits, with small claws, not modified for digging. Tail moderately short (ca. 50% of HB); naked. Adult body size very variable and changeable depending on status of individual within colony and on the abundance of food (Jarvis *et al.* 1991, O'Riain 1996, O'Riain & Jarvis 1998). No sexual dimorphism, except that reproductive ♀♀ have elongated bodies (O'Riain *et al.* 2000). A darkish-pink horizontal line, between the anus and clitoris, denoting the position of the sealed vaginal opening, distinguishes non-breeding ♀♀ from ♂♂. Skull: more rounded than other genera of bathyergids; infraorbital foramen round, very small (ca. 0.5 mm), thick-walled; upper incisors strongly pro-odont, ungrooved and extrabuccal; upper incisors protrude from just below a flattened nasal area; three upper and three lower cheekteeth (the only genus of Bathyergidae with this number) possibly reduced to two in some populations; re-entrant folds on cheekteeth visible only in young animals (Figure 107). Nipples arranged in two parallel rows from the axilla to the inguinal region; mean number of nipples 11.9 (range 9–15, $n = 249$) (Sherman *et al.* 1999).

Geographic Variation Animals from a population in S Kenya, where food was more abundant, were larger (mean 33.9 g, $n = 715$) than those from a population at Lerata in N Kenya (mean 21.3 g, $n = 204$) (Jarvis 1985, Brett 1991a, b).

Similar Species No other species is naked.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ. Recorded from hot dry regions of Djibouti, Somalia, E Ethiopia (excluding the highlands), and N and SE Kenya.

Habitat Semi-deserts characterized by high temperatures, low irregular rainfall (200–450 mm/annum) and plants with underground storage organs. Preferred soil type is hard consolidated lateritic loam, but may occur in many types of soil, ranging from fine sand to pure gypsum (Hill *et al.* 1957, Jarvis 1985). In Ethiopia, known only from arid lowlands at ca. 400–1500 m (Yalden *et al.* 1976).

Abundance Distribution is patchy; colonies are often widely dispersed but burrows of adjacent colonies can approach within a few metres of each other. Mean colony size is ca. 75 animals (range 2–300, $n = >50$). Population size difficult to estimate because mole-rats are subterranean.

Adaptations Subterranean, but may very occasionally venture above ground. Naked Mole-rats run forwards and backwards with equal ease, using their tail and sensory hairs to navigate. Burrow

Figure 107. Skull and mandible of *Heterocephalus glaber* (BMNH 7.4.1.12).

*Heterocephalus glaber*

system length depends on colony size and local food abundance. One completely excavated system containing 60 animals was 595 m long (Jarvis 1985), another with 85–90 animals was estimated (from telemetry studies over 12 months) to be 3 km long (Brett 1991b). Burrow systems consist of superficial networks (2–20 cm deep) of narrow (2.5–3 cm) foraging burrows, which are blocked off once the animals have finished foraging in the area. Superficial burrows lead down to wide (4–5 cm), long and relatively un-branched main burrows (>30 cm deep), which are dug to locate large tubers and patches of food; they also lead to nests (with several entrances), blind-ending toilet burrows and deep ‘bolt-holes’ – these may descend steeply to ca. 2 m (Jarvis 1985, Brett 1991b).

Temperatures in the main burrows vary little diurnally and seasonally (ca. 28–32 °C), and the humidity is high (ca. 80%). Naked Mole-rats are poikilothermic over most ambient temperatures, using behavioural means (huddling, basking close to the surface) to maintain body temperature close to ambient temperature (Buffenstein & Yahav 1991b). The well-vascularized hairless skin facilitates rapid heat exchange; and the high humidity in the burrow reduces water loss but prevents evaporative cooling. The basal metabolic rate is exceptionally low (40% of expected; McNab 1966); other energy-demanding features such as eyes and the optic regions in the brain are reduced to conserve energy. Energy-saving features help reduce life-time expenditure of energy, reduce cumulative oxidative damage and may possibly promote longevity of >26 years for captive breeders and non-breeders (O’Connor *et al.* 2002, Sherman & Jarvis 2002). In the wild, longevity is <3 years for non-reproductive animals and >10 years for reproductive animals (S. Braude unpubl.).

Foraging and Food Herbivorous, feeding exclusively on roots and swollen underground storage organs of plants. Food is widely dispersed in patches of small items or single large tubers (up to 50 kg). After rain, Naked Mole-rats dig long prospecting foraging burrows (up to 1 km/month) whose pattern is modified depending on the type

of food encountered. Burrows branch finely when patches of food are encountered, but not when they encounter large tubers, as these occur singly. Large tubers are partly eaten *in situ*, and the cavities are then packed with soil; many tubers are not totally destroyed and will regenerate (Brett 1991a, b). Non-reproductive animals of both sexes cooperate to dig foraging burrows: one animal bites the earth face, others collect excavated soil and form a chain to kick it back along the burrow to a larger animal who kicks it onto the surface through an open hole (Jarvis & Sale 1971, Braude 1991). Active mounds resemble an erupting volcano and are the site where most predation occurs. Most mounds are produced between 02:00 and 08:00h, times when predatory snakes are least active (Brett 1991a, b). In the laboratory, foragers (the non-reproductive animals) returning to the nest leave scent trails back to the food (Judd & Sherman 1996). Small items of food may be carried back to the nest where they are eaten by the young or by other colony members. Naked Mole-rats do not store food and all colony members (including the reproductive animals) will visit the primary source of food to feed.

Social and Reproductive Behaviour Naked Mole-rats are highly social, indeed they resemble eusocial insects in having reproductive division of labour, overlap of generations and cooperative care of young (Jarvis 1981, Sherman *et al.* 1991). Only one ♀ per colony is reproductively active (occasionally two); she is the dominant ♀ and suppresses reproduction in subordinates, not through pheromones but through stress-inducing behavioural interactions (shoving, passing over, etc.). She solicits mating with 1–3 consorts, who may remain her consorts throughout her life, occasionally continuing as reproductive ♂♂ to the succeeding reproductive ♀. When in oestrus, she emits a distinctive call and crouches in front of the ♂ or ♂♂ with tail to one side. Multiple paternity may occur in a litter (Faulkes *et al.* 1997a). There are no castes of workers but smaller non-reproductive animals (both adults and subadults) tend to perform more maintenance and foraging tasks than larger adults and also devote more time caring for the young. Larger adults tend to act as defenders in times of danger. The reproductive ♀ may remain as the only reproductive ♀ for many years (sometimes >20 years in the laboratory and >10 years in the wild). The oldest, largest ♀♀ (irrespective of relatedness) typically fight viciously for reproductive succession when a vacancy occurs (O’Riain 1996, Van der Westhuizen 1997, Jarvis & Sherman 2003). This is usually when the dominant reproductive ♀ dies, but also sometimes if she is sick or in some other way unable to dominate her colony; on such occasions she is usually killed by rivals. The lumbar vertebrae of the new dominant ♀ elongate during her first pregnancies, rendering her morphologically distinct from other ♀♀; this unusual situation is the first mammalian example of a behaviourally and morphologically distinct caste (O’Riain *et al.* 2000). Her enlarged abdomen enables her gut to hypertrophy to cope with the greatly increased energy demands of having large litters. It also enables her to remain mobile in the narrow confines of the burrow and thereby to maintain dominance over her colony. Males and ♀♀ remain fertile for >23 years (Buffenstein & Jarvis 2002, O’Connor *et al.* 2002, Sherman & Jarvis 2002). Colonies are strongly xenophobic, recognizing colony members by a cocktail of odours acquired from huddling in the communal nest and grooming in the communal toilet (O’Riain & Jarvis 1997). Because reproductive succession often occurs within the colony, many colonies are highly

inbred (Faulkes *et al.* 1997a). Occasionally fat, highly sexed, dispersers appear who, in laboratory experiments, will actively solicit foreign animals but not members of their own colony (O'Riain *et al.* 1996). These individuals may disperse to found new colonies, and perhaps even enter other colonies, but it is not known if dispersal is above or below ground. Small incipient and out-bred colonies are occasionally found in the wild; such colonies rarely last more than a year, indicating the high risks taken in attempting to 'go it alone' (O'Riain & Braude 2001, Jarvis & Sherman 2003).

The vocal repertoire of Naked Mole-rats is unusually large for a rodent (>18 vocalizations). Most vocalizations are in the 1–9 kHz frequency range and include high-pitched contact and aggressive chirps, a prolonged alarm scream, and aggressive grunting towards outside sources of danger. Larger individuals are mobilized, through the alarm calls, to defend the colony. Some vocalizations are restricted to specific animals in the colony, e.g. juveniles, reproductive animals (Pepper *et al.* 1991). Although most activities in the colony are accompanied by frequent vocalizations, the primary modes of communication, odour and touch, are also used (Sherman *et al.* 1991, O'Riain & Jarvis 1997).

Reproduction and Population Structure The one (occasionally two) reproductive ♀♀ in a colony breed throughout the year and have 3–4 litters/year. Gestation: 70–74 days. Litter-size 11.4 (1–28), *n* = 190. Postpartum oestrus Day 10. At birth, young weigh 1–2 g. First solids eaten by Day 14. Fully weaned at ca. 5 weeks (Jarvis 1991, O'Riain 1996). Young do not disperse but join the non-reproductive workforce. Only the reproductive ♀ lactates but, in many captive colonies, the entire colony (♂♂ and ♀♀) develop nipples prior to the birth of the young. This hormonal response to the pregnancy of the dominant ♀ by the colony may prime the animals to accept, and help care for, her young. The energetic costs of breeding are high; during pregnancy energy demands of the breeding ♀ increase by ca. 1300 kJ per gestation cycle, and lactation requires an additional 1515 kJ per day for an average-sized litter (Urison & Buffenstein 1995). Lactation lasts about five weeks. On weaning, the juveniles solicit caecotrophs from adults (special nutritious faeces routinely eaten by mole-rats as they are voided), and also eat food brought to the nest. The reproductive ♀ is the only adult that can solicit caecotrophs from other adults; they form an important dietary supplement to enhance her reproductive success.

Of all the ♀♀ in the colony, the dominant (reproductive) ♀ is identified by her elongated body, prominent nipples and perforate vagina. Reproductive ♂♂, often small emaciated-looking animals, are strongly bonded to the ♀ through repeated mutual anonasal interactions. In colonies with >1 reproductive ♂, there is no apparent competition for mating rights (Jarvis 1991). In the wild, the

reproductive ♀ and reproductive ♂♂ are usually the oldest members of the colony, and are distinctive in being less counter-shaded than non-reproductive animals (S. Braude unpubl.). Non-reproductive ♀♀ are prepubescent, have a vaginal closure membrane, small inactive ovaries and low levels of reproductive hormones (Faulkes & Abbott 1997); they can begin to have oestrus cycles within a week of removal from the colony. Non-reproductive ♂♂ have lower sperm counts, lower levels of reproductive hormones, and the sperm have low motility (Faulkes *et al.* 1994, Faulkes & Abbott 1997). Testes of reproductive and non-reproductive ♂♂ are abdominal. Over 95% of non-reproductive animals never have opportunity to breed (Sherman *et al.* 1992, Jarvis & Sherman 2003).

Predators, Parasites and Diseases Naked Mole-rats are preyed on by snakes (especially the Rufous-beaked Snake *Rhamphiophis oxyrhynchus* and Sand Boa *Eryx columbrinus*) and various raptors. They are especially vulnerable when they build mounds and eject soil onto the surface. Probably because of their nakedness, Naked Mole-rats have few ectoparasites; the most numerous are subcutaneous mites and chiggers (Parona 1895). Endoparasitic nematodes and cestodes are very rare (<1% of >300 animals autopsied from Mtito Andei; J. U. M. Jarvis unpubl.).

Conservation IUCN Category: Least Concern.

Local populations often highly inbred, and therefore potentially at risk from extinction by disease. There is little conflict with farmers because much of their habitat is not suitable for agriculture.

Family HYSTRICIDAE

PORCUPINES

Hystricidae G. Fischer, 1817. Mem. Soc. Imp. Nat., Moscow 5: 372.

| | | |
|------------------------------|------------------------|--------|
| <i>Atherurus</i> (1 species) | Brush-tailed Porcupine | p. 672 |
| <i>Hystrix</i> (2 species) | Crested Porcupines | p. 674 |

The Hystricidae contains three genera and 11 species distributed in Africa, the Middle East, the Indian sub-continent and South Asia, and on various islands in Indonesia and the Philippines (Woods 1984, Woods & Kirkpatrick 2005). The family, as a whole, is represented in many habitats including rainforest, savanna and semi-desert, although each species is rather restricted in its requirements. Two genera and three species occur in Africa.

Porcupines are best known for their large size and weight, and the possession of very coarse hair and spines on the back in some species. The spines (or quills) vary in size, shape, length and pattern according to the species and position on the body; however, all are pointed at the tip and provide a very effective defence against potential predators. The limbs are short, the fore- and hindfeet are plantigrade and each foot has five digits with claws. Locomotion is either a rather clumsy walk or a trot. The tail is short, and covered by quills, some of which may be modified into 'rattle quills'. Most species are brown or black in colour, although white bands on the spines of some species result in a generally paler colouration. Size categories of species in the family (based on mean head and body length) are given in the order Rodentia profile.

The skull is massive and high domed with an inflated nasal region in some species (*Hystrix* spp.), and with large pro-odont smooth-faced incisors, a large infraorbital foramen and relatively small zygomatic arches. Dental formula is $I^{1/1}, C^{0/0}, P^{1/1}, M^{3/3} = 20$. Upper incisor teeth without grooves. The premolar is retained for most of the individual's life, but is replaced late in life. The four cheekteeth have a unique wavy and complex pattern of enamel and dentine. On the upper molars, there are three labial (outer) folds and one lingual (inner) fold of the enamel. These folds usually become isolated early in life (due to wear) and then form 'islands' so that there are alternating lines and rings of enamel and dentine (Figure 108).

Porcupines are vegetarians, feeding on a wide variety of grasses, fruits, bark, bulbs and roots. They are nocturnal and travel at night along well-defined paths, often covering long distances in search of food. During the day they rest in burrows, which they may dig themselves, caves, or cavities under forest trees (such resting places are sometimes referred to as 'dens'). They are primarily terrestrial and unable to climb (except for one species in Asia).

Porcupines are solitary or gregarious, according to the species. In the social species, groups of several individuals of mixed sexes rest together in a single burrow. In *Hystrix*, parental care is well developed: ♂♂ look after young in the nest and accompany them when they begin

to forage above ground. Development of porcupines is slow (by comparison with other rodents), mainly because of their large size: gestation is 90–120 days, suckling continues for about two months, weaning occurs at about four months and adult size and reproductive maturity are not attained until about one year (or longer in the largest species). Porcupines are long-lived; in captivity, African species have survived for at least 20 years.

The family comprises genera and species that are very different from other rodents and the taxonomy of the family is not controversial. Hystricidae are placed in the suborder Hystricognathi (synonym: Hystricomorpha), together with the Bathyergidae, Petromuridae and Thryonomidae. Fossil porcupines in Africa date back to the Pleistocene, but older fossils are known from India and Eurasia (Woods 1984). Porcupines have radiated into two major groupings, which are sometimes considered as subfamilies (e.g. by Rosevear 1969): Atherurinae (*Atherurus*, *Triorchys*) consists of the smaller forest-living Brush-tailed Porcupines with poorly developed quills, and Hystricinae (*Hystrix*) consists of the larger savanna-living Crested Porcupines with well-developed quills. Following Woods (1993) and Woods & Kirkpatrick (2005), subfamilies are not listed here, even though there are considerable differences in the morphology and biology of each subfamily.

The two genera (*Atherurus*, *Hystrix*) in Africa are distinguished by size, tail length, character and size of the quills on the tail, and by the length of the nasal bones.

D. C. D. Happold

Figure 108. Cheekteeth of *Atherurus africanus* (left), *Hystrix cristata* (centre), *Thryonomys swinderianus* (right). White = enamel, stipple = dentine, black = infolding from outer surface, or space within enamel 'island'.

Genus *Atherurus*

Brush-tailed Porcupines

Atherurus F. Cuvier, 1829. Dict. Sci. Nat. 59: 483. Type species: *Hystrix macroura* Linnaeus, 1758.

The genus contains one African species and one Asian species. The genus is characterized by comparatively small size (cf. *Hystrix*), relatively long tail with a brush of 'rattle-quills' at the terminal end, and comparatively short dark quills on back which do not form a crest. The skull has small nasal bones which are shorter than the

frontal bones and end anteriorly to the anterior end of the zygomatic arches (cf. *Hystrix*). The genus is represented only in rainforest habitats. The single African species is *Atherurus africanus*.

D. C. D. Happold

Atherurus africanus.

Atherurus africanus AFRICAN BRUSH-TAILED PORCUPINE

Fr. Athérure d'Afrique; Ger. Afrikanischer Quastenstachler

Atherurus africanus Gray, 1842. Ann. Mag. Nat. Hist, ser.1, 10: 261. Sierra Leone (exact locality not specified).

Taxonomy Synonyms: *africanus* and *armatus* (West Africa), *centralis* (DR Congo) and *turneri* (East Africa). Subspecies: none. Chromosome number: not known.

Description Extremely large dark rodent, with comparatively short spines (quills) on back and flanks, and long tail ending in 'rattle quills'. Dorsal pelage dark brown; hairs rather sparse, modified into coarse thick spines, off-white at base, darkening towards the middle, blackish-brown (without alternating black and white bands as in *Hystrix* spp.) and sharply pointed at tip. Length of spines variable: 20 mm on neck, 35 mm on mid-back, up to 90 mm on rump and 25–45 mm on flanks. Fine hairs grow between the spines. Ventral pelage off-white to pale brown; 'hairs' softer and less spiny than dorsal hairs; length ca. 10–15 mm. Head sparsely covered with short dark coarse hairs; very long black vibrissae. Ears darkly pigmented, mostly naked. Fore- and hindfeet short and thick-set, covered with coarse dark brown hairs; five digits on each foot, all with small claws (except for short Digit 1 of forefoot). Tail short (ca. 40% of HB), thick and swollen at base with short black spines; tapers towards tip; terminal end with off-white or yellow 'rattle-quills', each with 4–5 hollow cavities along its length. When tail is shaken, the hollow cavities of the rattle-quills produce a rustling sound. Skull rather elongated (cf. *Hystrix* spp.) with 'normal' non-inflated nasal bones that end anteriorly to zygomatic arch; incisor teeth smooth and without grooves on outer surface (Figure 109, see also Figure 108). Nipples: 2 + 0 = 4.

Geographic Variation None recorded.

Similar Species

Hystrix cristata. Much larger, and with longer spines (up to 30 cm); nasal region of skull more inflated; rattle-spines of tail with only one large elongated hollow.

Figure 109. Skull and mandible of *Atherurus africanus* (RMCA 15288).

Atherurus africanus

Thryonomys swinderianus. Pelage coarse (without spines); tail without spines; each upper incisor tooth with three longitudinal grooves.

Distribution Endemic to Africa. Rainforest BZ and Rainforest–Savanna Mosaic from Gambia and throughout West Africa to E DR Congo; small populations in Uganda, Kenya and S Sudan. Bioko I. (Eisenbraut 1973).

Habitat Evergreen rainforests and gallery forests where there are hollow trees, buttress roots and soft soil, especially close to streams in little valleys. May occur in farmlands adjacent to forest within Rainforest BZ. Occurs over a range of altitudes from near sea level to 1400 m in E DR Congo (on volcanoes and Rwenzori Mts) and 1500 m on Mt Cameroon.

Abundance May be very abundant in some localities. Estimates vary according to locality (and method of calculation), e.g. 2.4–13.2/km² in Bayanga, Central African Republic (Noss 1998); 55/km² in Equatorial Guinea (Fa *et al.* 1995); 174 kg/km² = ca. 58/km² in Gabon (Feer 1993 in Jori *et al.* 1998).

Adaptations Nocturnal, terrestrial. Brush-tailed Porcupines do not dig burrows, but hide during the day in a den in hollow trees and hollow logs, or under roots of large trees. At Makokou, Gabon, they leave their hiding places at ca. 17:00h and return at about 05:30h (Emmons 1983). The activity pattern is usually trimodal, with two rest periods during the night, although bimodal on moonlit nights. Rest periods of 10–50 min are taken during each hour – these tend to be longer in the middle of the night than at the beginning or end, and when there is bright moonlight. On dark nights, ♀♀ do not normally take a rest period in the middle of the night (23:00–01:00h), although ♂♂ rest for some of the time. On nights close to full moonlight, the average time of inactivity/night was 3.5 hours, whereas on nights close to no moonlight, the average time of inactivity/night was 1.89 hours.

Brush-tailed Porcupines walk and trot on the forest floor, but they can also scramble and climb to a limited extent. While moving, the tail is held slightly upwards and backwards from the body, and sometimes at night the rustling of the ‘rattle quills’ can be heard even though the animal appears invisible. When alarmed or threatened, the spines on the back are raised and the rattle-quills are shaken; if attacked, the animal moves sideways and backwards with the pointed quills facing towards the opponent.

Brush-tailed Porcupines usually defecate regularly at the same place, either under a rock or in the den (Rahm & Christiaensen 1963).

Foraging and Food Vegetarian; feeds primarily on the leaves, flowers and fruits of forest trees (most of which have fallen from the higher storeys of the forest) and on some roots (Rahm 1962b). Where farms are adjacent to forest, maize, manioc (cassava), bananas and palm nuts are favourite foods. Occasionally, porcupines feed on carrion and earthworms (Rosevear 1969).

Social and Reproductive Behaviour At night, Brush-tailed Porcupines usually travel alone, although they may meet at feeding places. During the day, when resting in dens, they may be gregarious. In 22 dens investigated in Gabon, there were one (n = 12), two (n = 7) three (n = 1) or four (n = 1) animals in each den; associations were either ♂♂ and ♀♀, all ♂♂, or all ♀♀ (Emmons 1983). When living together (in captivity), porcupines show mutual grooming and auditory displays of dominance and submission. In some instances, they may form family groups (♂ and ♀ and young) (Rahm 1962b). The social organization of porcupines seems to be rather fluid, without the formation of monogamous pairs or cohesive groups.

Home-ranges (measured by radio-telemetry in Gabon) of adults varied from ca. 11 ha to 22 ha, ♂♂ on average having larger home-ranges than ♀♀. During the night, individuals travel rapidly along a well-defined network of pathways, averaging about 100 m in ca. 4 mins. Pathways connect dens with resting sites and foraging areas. Average nightly distances travelled are impressively large: ♂♂ covered 1697 m (on moonlit nights) and 2333 m (on dark nights), and ♀♀ covered 1646 m (on moonlit nights) and 1953 m (on dark nights) (Emmons 1983). Home-ranges of ♂♂ and ♀♀ tend to overlap. Most ♂♂ travel through most of the home-range every night (Emmons 1983), but do not display territorial behaviour.

Reproduction and Population Structure In E DR Congo, young animals have been found in most months of the year (Rahm 1962a), and it is likely that this pattern of reproduction occurs at other localities within the Rainforest BZ (see e.g. Jeffrey 1975). Gestation: 100–120 days (Rahm 1962a). Litter-size: 1–2 (Rahm 1962a, Weir 1974); 1–4 (Kingdon 1974). Females probably polyovular, so litter-size of only one young/litter in captivity may be related to captive conditions. Weight at birth: 150 g. The young are precocious at birth: the eyes are open, there are very soft spine-like hairs on the back and flanks, and walking on all four legs is possible. Sucking continues for ca. 2 months; solid food is first eaten at 2–3 weeks. Growth rate is comparatively slow: adult size is attained in ca. 300 days; but adult weight and sexual maturity are not reached until about two years (Rahm 1962a, Rosevear 1969). Females probably have 2–3 litters/year. Breeds well in captivity. Longevity: up to 22 years (Fa *et al.* 1995).

Predators, Parasites and Diseases The main predators are humans and Leopards *Panthera pardus*. Brush-tailed Porcupines are vigorously hunted by humans because of their succulent flesh and because (to a lesser extent) they may cause damage to crops. Carcasses are seen for sale as 'bushmeat' in many parts of the Rainforest BZ (see also *Thryonomys swinderianus*). In countries where surveys have been conducted (e.g. Nigeria [Martin 1983, Anadu *et al.* 1988], DR Congo [Colyn *et al.* 1987], Equatorial Guinea [Colell *et al.* 1994, Fa *et al.* 1995] and NE Gabon [Lahm 1993, quoted by Fa *et al.* 1995]), porcupines formed 6–19% of carcasses for sale in local markets on an annual basis. They are usually the third or fourth most numerous 'species' after antelopes (*Cephalophus* spp.), Cane Rats (*Thryonomys swinderianus*) and giant rats (*Cricetomys* spp.). In S Cameroon, they comprised 61% of carcasses (Muchaal & Ndjangui 1995, quoted by Jori *et al.* 1998). Studies to assess the impact of hunting on populations suggest that, in most places at the present time, Brush-tailed Porcupines are not overhunted, although their supposed rate of recruitment (based on rather slow reproduction) seems contrary to this assessment. One study (Feer 1993), where biomass was estimated at 174 kg/km² (= 58 individuals/km²), suggested that maximum sustained annual yield could be 44 kg/km²/year (= 14 individuals/km²/year).

Brush-tailed Porcupines are host to a malarial parasite, *Plasmodium atheruri* (Van den Berghe *et al.* 1958).

Conservation IUCN Category: Least Concern.

Brush-tailed Porcupines appear to be able to retain their population numbers except where hunting pressure is very high. However, loss of forest habitat as well as hunting are cause for concern in some parts of their range.

D. C. D. Happold

Genus *Hystrix* Crested Porcupines

Hystrix Linnaeus, 1758. Syst. Nat., 10th edn, 1: 56. Type species: *Hystrix cristata* Linnaeus, 1758.

The genus contains eight species (with many synonyms) widely distributed in Africa, the Middle East, India, South-East Asia and islands of the Indonesian archipelago (Woods & Kirkpatrick 2005). The genus may be divided into three subgenera: *Thecurus*, *Acanthion* and *Hystrix*, the latter subgenus containing both African species and being characterized

by having long quills along the length of the back, which can be erected to form a 'crest'. Representatives of the genus occur in savannas, woodlands, rocky areas, forests and plantations, but not in rainforests.

The genus is characterized by extremely large size (HB up to ca. 800 mm, WT up to ca. 20 kg, and the largest of African

Hystrix cristata.

Skeleton of *Hystrix cristata*.

rodents), coarse black bristles on head, limbs and ventral surface, long spines (quills) with alternating black and white bands on the back and flanks, short tail covered with black-and white banded 'rattle quills', and large thickset head. The hairs on the head and the quills on the back can be erected to form a backwardly facing crest when the animal is stressed or in danger. Quills are periodically lost (moulted) and replaced. Tail very short, with spines but without 'brush' of 'rattle-quills' (cf. *Atherurus*). The skull is large and thickset, rather narrow with a high domed forehead; nasal bones very large (extending over much of the top of the skull and exceeding in length the frontal and parietal bones combined) and ending posteriorly in line with the anterior or posterior end of the orbit (cf. *Atherurus*); zygomatic arch short; upper incisor teeth large, pro-odont and without grooves; and with four cheekteeth on each ramus (Rosevear 1969) (Figure 110). The common name, Crested Porcupines, refers to the erectile crest on the back (cf. *Atherurus*).

Crested porcupines are nocturnal and terrestrial, and live in holes or caves during the day. They live singly or in small family groups. They are vegetarian, eating a wide range of roots, tubers, bark and fallen fruits. On occasion they may gnaw bones, presumably to obtain additional calcium.

Figure 110. Skull and mandible of *Hystrix africaeaustralis* (RMCA 6191).

Within Africa, Ellerman (1940) recognized four species, although Corbet & Jones (1965) reduced the number to two, placing *stegmanni* as a synonym of *H. africaeaustralis* and *galeata* as a synonym of *H. cristata*. The two species are distinguished by length of the nasal bone, the ratio of the frontal bone to the nasal bone (frontal : nasal ratio), the characteristics of the rattle-quills, and colour of the rump (Table 46).

D. C. D. Happold

Table 46. Characters of *H. cristata* and *H. africaeaustralis* (mostly after Corbet & Jones 1965).

| Character | <i>H. cristata</i> | <i>H. africaeaustralis</i> |
|---|-----------------------------------|---|
| Length of rattle-quills | 5 cm or less | 6 cm or more |
| Diameter of rattle-quills | 2–5 mm | 5–7 mm |
| Colour of nuchal crest | Mostly dark | Mostly white |
| Colour of rump | Black | White |
| Relative length (%) of frontal bone to nasal bone | 23–38%, i.e. nasal bone very long | 49–68%, i.e. nasal bone not especially long |
| Relative length (%) of nasal bone to occipital–nasal length | 58–68% | 51–58% |

***Hystrix africaeaustralis* CAPE CRESTED PORCUPINE (CAPE PORCUPINE)**

Fr. Porc-épique de l'Afrique du Sud; Ger. Südafrikanisches Stachelschwein

Hystrix africaeaustralis Peters, 1852. Reise nach Mossambique, Säugethiere, p. 170. Near Tette, Querimba coast, Mozambique (exact locality uncertain, but ca. 10° 30' to 12° 00' S, 40° 30' E, at sea level).

Taxonomy Synonyms: *capensis*, *prittwitzi*, *stegmanni*, *zuluensis*. Subspecies: none. Chromosome number: $2n = 66$, $NF = 114$ (George & Weir 1974).

Description Extremely large rodent, the largest in Africa (together with *H. cristata*), with extremely long stiff hairs and spines (quills). Very similar in external appearance to *H. cristata*. Dorsal pelage with long stiff black or white hairs anteriorly, and with long smooth quills on mid-back and rump. Quills with alternating wide black and narrow white bands (usually four or five of each), ending in long white pointed tip; length varies, maximum 30 cm on rump. Nuchal crest (on neck and shoulders) formed of long wiry hairs, up to 45 cm, mostly white with black base. Crest and quills erectile when animal is frightened or threatened. Head, neck and limbs with coarse dark bristles (up to 50 mm). Mid-line of rump white. Head rather broad with short muzzle, swollen nasal region and long dark vibrissae. Eyes small and dark. Ears short, darkly pigmented. Limbs with short black hairs, relatively short and broad; five digits on each foot (Digit 1 of forefoot greatly reduced), each with claws. Tail very short, covered with short weak quills, usually invisible beneath quills of rump; some tail quills modified to form 'rattle-quills' or 'wine-glass quills' (ca. 6 cm long, 5–7 mm diameter), which rattle when tail is shaken. Skull large and rounded. Upper incisor teeth smooth; cheekteeth with complex folds of enamel and dentine; nasal bones long, 51–58% of occipito-nasal length, wide, extending posteriorly almost to level of anterior end of orbit; frontal-nasal ratio 49–68%. Nipples: 2 or 3 + 0 = 4 or 6.

Geographic Variation None recorded.

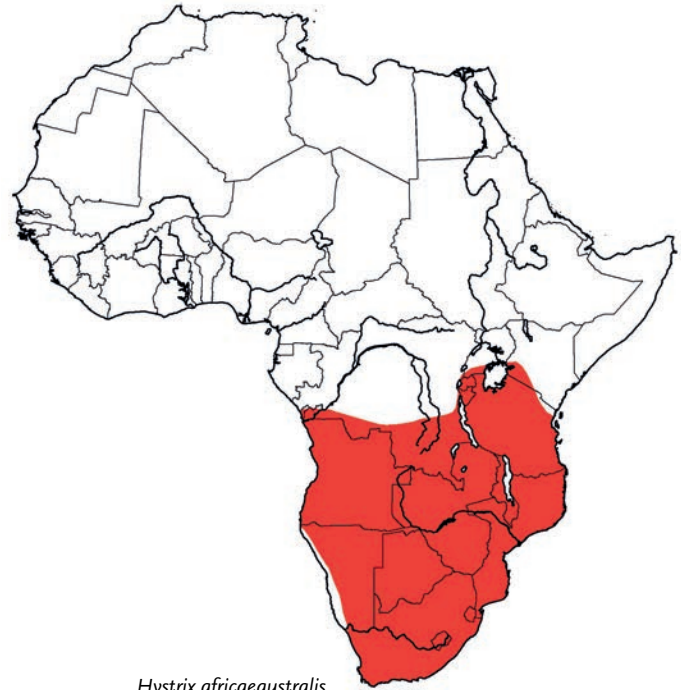

Similar Species

H. cristata. Nasal bones >57% of occipital-nasal length; frontal-nasal ratio 23–38%; mid-line of rump black or mottled; western and central Africa; sympatric with *H. africaeaustralis* in parts of S Uganda, S Kenya and Tanzania.

Distribution Endemic to Africa. Widespread throughout southern Africa in four biotic zones (Zambezian Woodland, South-West Arid, Highveld and Coastal Forest Mosaic BZs). Recorded from South Africa northwards to Angola, S DR Congo, Tanzania, S Kenya and S Uganda. Parapatric with *H. cristata* in East Africa. Probably not present on Zanzibar I. (*contra* Kingdon 1974; see *H. cristata*).

Habitat Savanna, semi-deserts and forested areas, but not in swamps, moist forests and barren deserts. Common in rocky hill country; shows preference for *Burkea* savanna (see below). Also occurs in farmlands and forest plantations.

Abundance Relatively common in suitable habitats, although rarely seen because of nocturnal habits. Many records are based on the presence of discarded quills.

Hystrix africaeaustralis

Adaptations Nocturnal and terrestrial. Rests during daytime in caves, natural crevices and burrows. Cape Crested Porcupines are good diggers and may excavate their own burrows or may take over burrows made by other animals (e.g. Aardvarks). Burrows may be complex with several chambers. The gait is either a shuffling plantigrade walk or (if frightened or in danger) a clumsy gallop.

In South Africa, Cape Crested Porcupines may have a significant effect on their environment due to their habit of chewing the bark and roots of many species of trees, and digging for food. They are especially fond of the bark of *Burkea africana* and *Dombeya rotundifolia* and preferentially chew on these species (De Villiers & Van Aarde 1994); by removing the bark, trees are more susceptible to fire and may be killed during subsequent savanna fires. Chewing bark also results in coppicing and a reduction in the number of trees reaching maturity (Yeaton 1988). The combination of fire and Cape Crested Porcupines has a strong effect on the species composition and structure of *Burkea* savanna, and helps to maintain the mosaic of grasslands and woodland patches. Cape Crested Porcupines rarely feed on the bark of *Acacia* trees and do not prevent the development of mature *Acacia* woodlands. As a result, *Acacia* woodland has the potential to spread into regions where *Burkea* woodlands have been partly destroyed. Digging for food disturbs the soil and increases the chances of seed germination; seedling density and diversity may be higher where porcupines (as well as Aardvarks *Oryzomys afer* and Bat-eared Foxes *Otocyon megalotis*) have been digging than on flat hard soil surfaces (Dean & Milton 1991).

Cape Crested Porcupines have a lower metabolic rate than expected for their size, and can maintain a constant body temperature (T_b) when

ambient temperature (T_a) ranges between 13 °C and 30 °C. When T_a is low, T_b is maintained at about 37 °C mostly by increasing metabolic rate and decreasing heat loss. When T_a is 30 °C, there is an increase in ventilation rate and loss of water through the lungs, which prevents body temperature from rising to a dangerously high level. If T_a is 37 °C—a condition not normally experienced by free-living porcupines because they are nocturnal—hyperthermia occurs. Low metabolic levels, efficient heat loss when ambient temperature is high and ability to regulate body temperature over a wide range of conditions, enable these porcupines to live in a wide variety of habitats (Haim *et al.* 1990a, b).

Foraging and Food Omnivorous. Feeds primarily on roots, bark, bulbs, tubers, berries and other fruits, and shoots of herbs (De Graaff 1981, De Villiers *et al.* 1994). Cape Crested Porcupines forage above ground, digging for roots and bulbs. They may cause damage to crops and forestry plantations. In captivity, they eat more during winter (10 °C and short days) than during summer; an increase in food consumption (and hence energy production), together with a decrease in heat loss, appear to be mechanisms that allow porcupines to be active during cold weather (Haim *et al.* 1990b). Food consumption is correspondingly reduced during summer conditions.

Social and Reproductive Behaviour Live in monogamous pairs, usually with their young. Family groups live together in burrows, although group may split up while foraging at night. Size and the duration of family group seem to depend on opportunities for young to disperse when they become mature. Family groups may, on occasion, be large—up to 14 individuals have been found in a single burrow—and composed of two (or more?) pairs with young (Van Aarde 1987a). Within a family group, only the monogamous pair reproduces. Offspring disperse when mature provided there are areas where territories may be established and where food is not limiting. If dispersal opportunities are limited, offspring may stay with parents, forming large family groups, but reproductive suppression prevents offspring from being reproductively active (Corbet & Van Aarde 1996).

Home-ranges are large. In *Burkea* savanna in South Africa (Corbet & Van Aarde 1996), mean home-range area in summer was 215 ha, although only about 80 ha of the range (the 'core area') was used extensively. Home-ranges of different individuals overlapped, especially during winter, although the core area was used exclusively by a single individual. Hence individuals are probably territorial with a small territory, advertised by scent marking, within a larger home-range. Winter home-ranges and territories are smaller than those in summer (e.g. 142 ha and 55 ha, respectively). Each territory has 1–3 burrow systems (Van Aarde 1987b). Porcupines that live and feed in crop areas have larger ranges than those living in natural savanna, and without any seasonal differences in area.

Porcupines communicate with each other with various piping calls and pig-like grunts. Members of a monogamous pair indulge in daily bonding behaviour (grooming, etc.), and ♀ conceives only after living with her partner for at least 90–100 days. Parental care of young is well developed. In the burrow, mother suckles young while in a crouching position. Male lives in the burrow with ♀ and young and, later, escorts them on foraging excursions and protects them from predators (Van Aarde 1997). Family group remains intact until young disperse at adulthood.

Reproduction and Population Structure Breeding season varies according to locality. In South Africa (30° S), in the wild, births occur mostly in spring and summer, from Aug to Mar with a peak in Jan (Van Aarde 1987a). Most ♀ ♀ more than 24 months of age are reproductively active (88–95%) during the breeding season. Younger ♀ ♀ (12–24 months) are less reproductively active (63–88%), and ♀ ♀ aged less than 12 months rarely breed. In the drier regions of the Karoo in South Africa, births coincide with peaks in rainfall (Skinner *et al.* 1984). Times of reproductive activity in northern parts of geographic range are uncertain, although there is some evidence that births may occur in all months of the year.

Mean oestrus cycle: ca. 35 days (Weir 1974). In South Africa, captive ♀ ♀ are polyoestrous, with most ♀ ♀ cycling every 28–36 days (Van Aarde 1985). Gestation: 93–94 days. In captivity (in South Africa), litter-size 1.5 (1–3); of 165 litters, 58% had a single young, 32% had twins and 9% had triplets (Van Aarde 1985). Weight at birth 300–440 g. Each young (whether singletons or twins) weighs ca. 2% of maternal weight; overall litter weight (young, placenta, etc.) weighs ca. 10% of maternal weight (Weir 1974). Mammary glands are situated on the side of the thorax. Twins usually suck from opposite nipples. The average length of lactation is 101 days, but may continue for 163 days. Mean litter interval of captive ♀ ♀ is 385 (269–500) days; thus mothers give birth to only one litter/year (Van Aarde 1985).

Young are precocious (although relatively small) at birth, with eyes open and with soft spines and soft quills on the back. They remain in the burrow for 7–9 weeks, a much longer period of time compared with other rodents, emerging for the first time when the quills have hardened. This behaviour (as well as huddling with siblings and parents) probably conserves energy, which can be channelled into growth rather than being used for activity above ground, and provides protection before the quills are fully developed. Growth in body weight is linear until a weight of 11–12 kg is attained at about 52 weeks; thereafter, there is a slow increase in weight to the full adult size of 12–18 kg (Van Aarde 1987a). Sexual maturity occurs when 12–24 months of age. The approximate age of an individual can be determined by tooth wear until adult weight is attained; thereafter age cannot be determined.

Little is known about age structure of populations. In N South Africa, age structure varied markedly during a 2-year study (Van Aarde 1987b). When categorized into four age categories (<6 months, 6–12 months, 12–24 months and >24 months), the proportions of each age category during one of the years were 20–40%, 10–25%, <10–25% and 30–50%, respectively ($n = 118$). Because young are born in many months of the year, there is no period when young of the year form a really large proportion of the population (cf. small rodents). In the second year, the presence of young was more seasonal, perhaps because fewer adults were breeding. The probability of survival of young to 18 months of age was 0.46 in the first year and 0.33 in the second year (Van Aarde 1987b). Changes in the age at first reproduction are probably responsible for changes in population growth rates and population structure. There is no information on porcupine populations in the northern part of their geographic range.

Predators, Parasites and Diseases Predators include large cats and hyaenas, although the quills and behavioural characteristics

(see above) provide considerable protection from predators. Some humans hunt Cape Crested Porcupines for food, and the quills are used for ornaments. Many species of mites, fleas and ticks have been recorded (details in De Graaff 1981).

Conservation IUCN Category: Least Concern.

Not listed in any category of threat in South Africa (Smithers 1986b). As for *H. cristata*, the species is generally uncommon and populations are scattered, although some areas maintain good population numbers (see above).

Hystrix cristata NORTH AFRICAN CRESTED PORCUPINE (CRESTED PORCUPINE)

Fr. Porc-épique de l'Afrique du Nord; Ger. Nordafrikanisches Stachelschwein (Kamm-Stachelschwein)

Hystrix cristata Linnaeus, 1758. Syst. Nat., 10th edn, 1: 56. 'Asia' (restricted to Rome, Italy by Thomas 1911).

Taxonomy The Crested Porcupines of Africa north of the Equator were known as *H. cristata* (western and northern Africa) and *H. galeata* (eastern Africa). Corbet & Jones (1965) showed that *cristata* and *galeata* exhibit wide overlap in all characters, and therefore should be regarded as conspecific. Likewise, various described races also show overlap in characters. The holotype, from Italy, was probably descended from North African individuals that had been imported, perhaps during Roman times. Synonyms: *aerula*, *cuvieri*, *daubentoni*, *europaea*, *galeata*, *occidanea*, *senegalica*. Subspecies: none recognized here (but see Geographic Variation). Chromosome number: 2n = 66, NF = 114 (George & Weir 1974).

Description Extremely large rodent, the largest in Africa (together with *H. africaeaustralis*), with extremely long stiff hairs and spines. Very similar in external appearance to *H. africaeaustralis*. Dorsal pelage with long stiff black or white hairs anteriorly, and with long smooth spines (quills) on mid-back and rump. Quills with alternating wide black and narrow white bands (usually four or five of each), ending in long white pointed tip; length varied, maximum 30 cm on rump. Nuchal crest (on neck and shoulders) formed of long wiry hairs, up to 45 cm, mostly black. Crest and quills erectile when animal is frightened or threatened. Head, neck and limbs with coarse dark bristles (up to 50 mm). Mid-line of rump black or mottled. Head rather broad with short muzzle, swollen nasal region and long dark vibrissae. Eyes small and dark. Ears short, darkly pigmented. Limbs with short black hairs, relatively short and broad; five digits on each foot (Digit 1 of forefoot greatly reduced), each with claws. Tail short, usually invisible beneath quills of rump; tail covered with short weak quills, some modified to form 'rattle-quills' or 'wine glass quills' (ca. 5 cm long, 2–5 mm diameter), which rattle when tail is shaken. Skull large and rounded. Incisor teeth smooth; cheekteeth with complex folds of enamel and dentine; nasal bones very long, >57% of occipito-nasal length, wide, extending posteriorly almost to level of posterior margin of orbit; frontal : nasal ratio 23–38%. Nipples: 2 or 3 + 0 = 4 or 6.

Hystrix cristata

Geographic Variation Populations show differences in occipito-nasal length, zygomatic width, length of nasals and in overall size. North African (and Italian) individuals are the smallest in size, those from West Africa are intermediate, and those from eastern African (*galeata*) are the largest. However, there is considerable overlap, and differences are probably clinal (Corbet & Jones 1965). In West Africa, Rosevear (1969) refers to two races (subspecies) that differ in size: the largest is *senegalica* from the savanna woodlands (total length about 900 mm, HF 120 mm, GLS over 140 mm, and P⁴–M³ over 32 mm), and the smallest is *aerula* from the semi-desert (TL about 700 mm, HF 80–90 mm, GLS under 140 mm, and P⁴–M³ 30 mm or less).

Similar Species

H. africae australis. Nasal bones 51–58% of occipito-nasal length; frontal-nasal ratio 49–68%; mid-line of rump white; southern Africa; parapatric with *H. cristata* in parts of S Uganda, S Kenya and Tanzania.

Distribution Widespread in Mediterranean Coastal BZ, Sudan Savanna and Guinea Savanna BZs, Northern Rainforest–Savanna Mosaic, and Afromontane–Afroalpine BZ of Ethiopia. Disjunct distribution in parts of Sahel Savanna and Sahara Arid BZs. Recorded from coastal regions and parts of Atlas mountains of Morocco, Algeria and Tunisia; coastal areas of Libya. Probably extinct in Egypt (Osborn & Helmy 1980). Isolated populations in semi-desert habitats in Air (Niger) and Adrar des Iforas (Niger). Widespread throughout West Africa from Senegal to Cameroon, and in NE DR Congo, Rwanda, Ethiopia, Uganda, Kenya and N Tanzania, Zanzibar I. Probably present in S Chad and Central African Republic. In Ethiopia, occurs from sea level to about 3550 m. Also occurs (as an introduced species) in Italy, Sicily, Albania and N Greece (Woods & Kirkpatrick 2005).

Habitat Semi-desert, woodland and grassland savannas, especially where rocks and caves are present. In Algeria and Morocco, lives in forested hills and steppes, but not in the Sahara Desert. Appears to be very tolerant of a wide range of habitats and climates, including warm coastal scrub, dry semi-desert and cold grasslands on mountains. In Ethiopia, may be attracted to irrigated large-scale farmlands, where they can become pests on crops (Yalden *et al.* 1976).

Abundance Uncertain because rarely seen; thought to be quite common in suitable habitats in most parts of range. Many records are based on the presence of discarded quills.

Adaptations Nocturnal, although in captivity may be active in daylight. Terrestrial. During the day, these crested porcupines rest in caves, holes under trees or made by other animals, and in rocky crevices. They do not dig their own burrows. Locomotion is a walk or slow trot, and because of their large size, they are unable to climb. When frightened or threatened, the crest and quills can be erected (making the animal look much bigger than it really is) and the quills are rattled. If in danger, the animal moves sideways or backwards with the pointed tips of the erect quills facing the source of danger, and stamps its feet (Ewer 1968). If really provoked by a potential predator, an individual charges backwards forcing some of its quills into the predator; the quills are easily detached and may stick (like arrows) in the predator. Quite severe wounds can be caused by these quills. This behaviour, and the sharpness of the quills, provides the porcupine with a very effective defence mechanism (even against potential predators such as Lions *Panthera leo*).

There are many reports of porcupines (this species and probably also Cape Crested Porcupines) gathering and chewing on bones, and dens being littered with bones. These habits are thought to be associated with wearing and sharpening the incisor teeth, perhaps with the added benefit of providing an additional source of calcium and minerals (Kingdon 1974).

Foraging and Food Herbivorous. Principal foods are fruits, roots, bulbs and bark. Cassava, sweet potatoes and groundnuts are eaten in savanna farmlands.

Social and Reproductive Behaviour Crested Porcupines are social and gregarious. Secretions from anal glands are used to mark home-ranges and to indicate an individual's presence, and vocal sounds are used (as in many species of hystricomorph rodents) for male–female interactions, to warn conspecifics of danger and during aggressive encounters. During courtship, ♂ approaches ♀ using a 'bipedal approach' gait, and he also grooms the ♀. Females solicit copulation by a 'tail-up rump' display (Mohr 1965, Kleiman 1974). Several individuals may rest together in a burrow (Delany 1975).

Reproduction and Population Structure Gestation: 112 days. Litter-size: 2 (1–4). Weight of young at birth ca. 1000 g. Ratio of litter weight/maternal weight is 10% – a low percentage compared with most hystricomorph rodents (6–60%) (Weir 1974). Young born with eyes open and soft spines (Rosevear 1969). Mother suckles while sitting because nipples are placed on the side of thorax. Males assist with retrieving and grooming young, and will rest with young in the burrow (Mohr 1965). Young weaned at 16 weeks of age.

Predators, Parasites and Diseases North African Crested Porcupines have few predators because of their defensive behaviour (see above). Humans may hunt them for food, but they are not a major source of 'bushmeat' (cf. *Atherurus africanus*, *Thryonomys swinderianus* and duikers; for details, see references in profiles for these species). Two species of tsetse flies (*Glossina submorsitans* and *G. tachinoides*), which transmit sleeping sickness to humans, are recorded as feeding on the blood of porcupines.

Conservation IUCN Category: Least Concern.

North African Crested Porcupines are uncommon and populations are scattered (see above) and hence may be in need of protection.

Measurements

Hystrix cristata

HB: 650–850 mm

Family PETROMURIDAE
NOKI (DASSIE RAT)

Petromuridae Wood, 1955. J. Mamm. 3: 184.

| | | |
|-----------------------------|------|--------|
| <i>Petromus</i> (1 species) | Noki | p. 681 |
|-----------------------------|------|--------|

The family contains only a single species, *Petromus typicus*. It is restricted to Namaqualand (South Africa), Namibia and extreme SW Angola, occurring only on mountains and rocky outcrops of the semi-arid western escarpment and adjoining areas of the Namib Desert.

The single species is unusual in its external appearance, looking like a mixture of a rat and a squirrel. It is about 200 mm long, with brownish or brownish-grey coarse pelage, and longish tail covered with long dark bristle-like hairs. The head is relatively large, rather flattened with pointed muzzle and long vibrissae. Eyes large; ears moderate and rounded, not protruding above the line of the head. Limbs are short, and feet are broad and naked with well-developed pads; forefoot with four digits (Digit 1 rudimentary); hind-foot with five digits, all with short sharp claws. The ribs are particularly flexible so the body can be pressed flat (when under boulders and rock slabs) without injury. Pectoral nipples are situated laterally behind the shoulders (as in Cane Rats). Size categories of species in the family (based on mean head and body length) are given in the order Rodentia profile.

The skull exhibits typical hystricomorph characters as well as those associated with a rupicolous life-style: infraorbital foramen enlarged,

jugal bone of zygomatic arch enlarged dorsoventrally, cranium flattened dorsoventrally (height above M¹ about 43% of zygomatic width), rostrum narrow (especially in relation to the wide orbital area, zygomatic arches and braincase), and without an interorbital constriction. Dental formula: I ¹/₁, C ⁰/₀, P ¹/₁, M ³/₃ = 20. Upper incisors narrow, not grooved, opisthodont, yellowish. Anterior palatal foramina wide at both ends (similar in width to the upper molars), reaching posteriorly to between premolars; septum between each foramen very narrow. Cheekteeth show a unique structure: four cheekteeth (one premolar, three molars), hypsodont and four-rooted. Each upper cheektooth has deep infolding on the lingual side giving the impression that it consists of two sections. Similar infoldings occur on the labial side but, because of increased wear on this side, they are less obvious in older animals. Each lower cheektooth has deep infoldings on the labial side, and most wear on the lingual side. Auditory bullae considerably inflated, with a well-developed paraoccipital process on the posterior side, which does not project below the level of the bullae. Mandibles very wide posteriorly, with a distinct ridge on the lower outer side, stretching from below the first molar to the narrow angular process (Figure 111).

Nokis are adapted for desert and semi-desert life on rocky habitats. They live in family groups amongst boulders of outcrops and mountainsides, or amongst rock slabs in broken terrain. They are diurnal, but less active during the warmer hours of the day, and they forage on grass and leaves of shrubs and trees up to 20 m away from the protection of rocks.

The phylogenetic relationship of the Petromuridae to other hystricognaths is uncertain. Simpson (1945) grouped Petromuridae with the Octodontoidea, a superfamily proposed by him. Wood (1955) re-established the suborder name Hystricognomorpha for Old World taxa of the hystricognaths and proposed the superfamily name Thryonomyoidea (for the Cane Rats and Dassie Rat) as well as the use of Petromuridae to replace Petromyidae (see Woods & Kirkpatrick 2005). Lavocat (1974) supports the differentiation between Hystricognathi of the Old and New World by using the terms Phiomorpha and Caviomorpha respectively, but prefers to group them together into a higher clade Hystricognathi (suborder). Mess (1999), using the analysis of molecular data (Catzeflis *et al.* 1995), the structure of the rostrum (Ade 1998) and of the ethmoid- and orbital regions (Mess 1997), grouped *Petromus*, *Hystrix* and *Thryonomys* under the Hystricoidea – a name proposed by Gill in 1874. Patterson & Wood (1982) split the Petromuridae in three subfamilies: the Petromurinae for the extant *Petromus*, and the Phiomiyinae and Diamantomyinae for extinct species. At present, there is one genus and one species, *Petromus typicus*.

Figure 111. Skull and mandible of *Petromus typicus* (BMNH 28.9.11.377). This specimen is from a young animal and shows infoldings on the labial side of the cheekteeth. See family profile for details.

C. G. Coetzee

Genus *Petromus* Noki (Dassie Rat)

Petromus A. Smith, 1831. S. Afr. Quart. J. 1(5): 10. Type species: *Petromus typicus* A. Smith, 1831.

A monotypic genus occurring only in the South-West Arid BZ. Characters of the genus are given in the family profile above. The single species is *Petromus typicus*.

C. G. Coetzee

Petromus typicus.

Petromus typicus NOKI (DASSIE RAT)

Fr. Rat des rochers du Namibie; Ger. Felsenratte

Petromus typicus A. Smith, 1831. S. Afr. Quart. J., ser. 1, 5: 11. Mountains towards the mouth of the Orange River, Little Namaqualand, Northern Cape Province, South Africa.

Taxonomy Originally described in the genus *Petromus*, but in 1834 Smith referred to the genus as *Petromys*. This mis-spelling prevailed for some time and influenced the spelling of the higher categories – Petromyidae (e.g. Roberts 1951) and Petromyinae (Ellerman 1940). The erroneous spelling was used also in the descriptions of 11 of the 13 described forms (based mainly on coat colour). Synonyms: *ausensis*, *barbiensis*, *cinnamomeus*, *coetzeei*, *cunealis*, *greeni*, *guinasensis*, *karasensis*, *kobosensis*, *majoriae*, *namaquensis*, *pallidior*, *tropicalis*, *windhoeckensis*. Subspecies: none recognized here (but see Geographical Variation). Chromosome number: not known.

Description Large, squirrel-like diurnal rodent with longish pelage and hairy tail. (The term 'large' is ambivalent here; the species is large by murid or sciurid standards, but it is the smallest of non-fossorial hystricomorpha rodents; see Order profile.) Dorsal pelage dark blackish-brown, dark grey or pale buffy-yellow (depending on locality; see below); hairs pale grey at base. Ventral pelage slightly paler than dorsal pelage. Head dorsoventrally flattened, similar in colour to dorsal pelage, paler on nose, lips and around the eyes. Vibrissae long. Eyes large. Ears slate-gray to black, sparsely covered with extremely short hair, small, oval, not protruding above the line of the head. Limbs short; feet broad, well covered with hair on upper surface, naked on undersurface. Forefoot with four digits (Digit 1 rudimentary), three plantar pads at the base of digits and two on palm. Hindfoot with five digits, three plantar pads at base of the toes and only one pad on sole. All digits with short sharp claws. Tail long (ca. 85% of HB), densely covered with long hairs (but not as long as in a squirrel), similar in colour to rump at base, black on terminal three-quarters; tail normally rests on (or is held close to) the ground, not squirrel-like over the body. The scrotum is not conspicuous. Skull: see family profile. Nipples: 2 + 1 = 6; anterior nipples placed laterally behind shoulders; inguinal nipples often absent.

Geographic Variation Although no subspecies are recognized here, three groups may be distinguished, based on the colour of the dorsal pelage, which varies from dark brown in the south to pale brown in the north, and pale to dark grey towards the higher rainfall area of the Otavi Mts complex, leading to south–north and west–east coat clines in colour. The geographical groups may be linked to named forms, as follows:

- Southern buffy-brown group (Namaqualand, along the Orange R., and S Namibia) corresponding to the nominate form (*typicus*) and to *ausensis*, *barbiensis*, *cinnamomeus*, *karasensis* and *namaquensis*.
- Pale brown group (C and NW Namibia to SW Angola) corresponding to *coetzeei*, *greeni*, *kobosensis*, *majoriae*, *pallidior*, *tropicalis* and *windhoeckensis*.
- Grey group (Otavi Mountain area towards the eastern Kaokoveld and northwards to the Kunene R. valley below the Rua Cana Falls and east of the Baines Mts) corresponding to *cunealis* and *guinasensis*.

However, preliminary cranial measurements do not support these divisions (C. G. Coetzee & C. Chimimba unpubl.).

Similar Species

Procavia spp. Similar in appearance, especially when the Noki has lost its tail, as is the case in about 10% of animals; sympatric and often syntopic.

Xerus princeps. Larger; comparatively longer HB; tail with long bushy hairs; may be sympatric and syntopic.

Graphiurus spp. Smaller HB; pelage woolly, nocturnal; upper incisors form an inverted V-shape.

Distribution Endemic to Africa. South-West Arid BZ (Namib Desert). Recorded in rocky habitats in extreme SW Angola, W Namibia and extreme NW South Africa where mean annual rainfall

*Petromus typicus*

is ca. 50–400 mm. Found in canyons of the Namib where the mean annual rainfall can be as low as 35 mm/year. In Angola, limited to the outcrops and broken terrain on the eastern side of the Namib, approximately as far north as 16°S, 12°E and along the Kunene R. inland to the Rua Cana Falls.

Habitat Occurs amongst granite, schist slabs and sedimentary rocks; and amongst the boulders of outcrops, canyons and mountain slopes where rock crevices provide shelter and nesting sites. May also occur amongst boulders and rock accumulations that are some distance away from mountains and outcrops. Normally absent on steep, rather bare rock faces although such rock faces may be used during the day for basking. Habitats with deciduous and evergreen trees and perennial shrubs provide a more stable food resource on outcrops and mountains of the Namib (Rathbun & Rathbun 2005). Also recorded in marginal habitats where annual rainfall is <100 mm and grasses are restricted to narrow strips in gullies and below boulders; here, run-off of water after sporadic rains and from condensed fog, provides additional moisture.

Abundance Generally rare. Populations widely scattered, and localized, but may be quite abundant in favoured localities. At Tumasberg, Namibia (a very arid locality with mean annual rainfall of 39 mm), density was 2.8/ha (biomass 431 g/ha) (Withers 1979). In the winter rainfall region of SW Namibia, where succulents and shrubs provide a year-round source of food, maximum density was 28/ha (biomass 3221 g/ha) (Coetzee 2002). At Tumasberg, *P. typicus* comprised 16% of trapped small mammals, and was less numerous than two other sympatric rodents, *Petromyscus collinus* (60%) and *Aethomys namaquensis* (16%) (n = 250; 6 spp.; Withers 1979).

Adaptations Nokis are well adapted to life in rocky habitats in arid environments. Diurnal and rupicolous. Temperature regulation plays an important role in their activities. They are most active during early morning and late afternoon. Significantly more time is spent basking

during the first three hours after sunrise than during a similar period during the late afternoon (Rathbun & Rathbun 2006b). During daytime, they bask on the tops of boulders or on ledges, or rest underneath rocky overhangs that protect them from avian predators and prevailing dry winds. Basking is less common during the hot season than during the cold season of the year (Rathbun & Rathbun 2006b). Nokis tend to bask on the eastern side of a small outcrop or rock accumulation in the morning, and on the western side during the afternoon (C. G. Coetzee unpubl.). They may even lie spread-eagled on warm rocks (Shortridge 1934, Coetzee 2002). Solar basking, moving from sunny to shady areas, and sheltering at night amongst rocks to avoid extreme external temperatures, form an important part of the Noki's behavioural control of temperature (Rathbun & Rathbun 2006b). Withers *et al.* (1980) recorded a body temperature (T_b) of 34.9 ± 0.5 °C (n = 6) in laboratory animals. Temperature recorders on the necks of three wild-living Nokis recorded a mean temperature of 34.9 °C (range 27.8–42.2 °C) when basking in the sun, 33.3 °C (range 25.8–38.2 °C) when active during the day, and 34.8 °C (range 29.2–38.4 °C) when resting in a night shelter; thus the mean temperature near the skin (and hence not T_b) remains fairly constant (with similar ranges) during the various daily activities and changing environmental temperatures at different locations (Rathbun & Rathbun 2006b). Nokis do not enter torpor at any time.

Nocturnal activity outside nests is restricted (and hence remains of Nokis in owl pellets are rare). Nests are built between rocks and underneath boulders and rock slabs, often with an untidy accumulation of sticks at the entrances. Rock entrances leading to shelters are small, averaging only ca. 44–69 mm high (Augrabies Falls N. P., South Africa; George & Crowther 1981). Nokis are well adapted to squeezing into rock crevices partly because the skull is dorsoventrally flattened and the ribs are compressible (see family profile).

Nokis have a low minimum water turnover rate (0.029 ml/g/day), comparatively large medullary area of the kidney and low daily energy expenditure. Their diet is water-rich stems and succulents; when fed experimentally on dry seeds and without water, they lose 20–35% of their body weight and are unable to survive (Withers *et al.* 1980). George (1981b) found that '*Petromus* can maintain its weight in captivity on 5.7 g dry weight of mixed vegetation containing 0.5 g protein.' In the wild, there is some evidence that water turnover rate is higher when advective fog is present (Withers *et al.* 1980), suggesting that they may drink condensed fog water in areas and at times when this water source is available. The daily energy expenditure of captive individuals fed on dry bird seed (with *ad libitum* water) was 0.55 kJ/g/day, which is 55% of the expected value on the basis of size (Withers *et al.* 1980). The physiological characters of Nokis suggest that they are well adapted to xeric conditions (Withers *et al.* 1980).

Foraging and Food Herbivorous. Nokis feed on a wide variety of leaves, flowers, stems and fruits, with variations depending on season and locality. They forage by cutting leaves or grass stalks, and then quickly return to the shelter. They climb shrubs and small trees such as *Scotia afra*, *Hermannia stricta* (George 1981b), *Boscia* and *Lycium* species to nibble the leaves. Fruit of cucurbitaceous plants (e.g. *Cucumis dinteri*) and flowers of daisies such as *Arctotis*, *Gazania* and *Dimorphotheca* sp., leaves of *Mesembryanthemum* succulents and *Aloe* sp. are also eaten. When herbs such as *Tribulus zeyheri* are collected and brought to the resting area, the stems are usually eaten before the

leaves (Coetzee 2002). In the wild (and in captivity), they collect and eat both green and dry grass stalks when both are available. In the central Namib and near Windhoek, these grasses include species of *Eragrostis*, *Enneapogon* and *Stipagrostis*, as well as *Cenchrus ciliaris* and *Anthehora pubescens*. During the dry season, they eat new green leaves on the stems of *Grewia flavescens* and *G. tenax*, dry leaves on the ground, flowers on the stems (and on the ground) of *Sterculia africana* and *Adenolobus garipensis*, and the flowers and/or seed pods from stems of *Boscia albitrunca* (Rathbun & Rathbun 2005). In the winter rainfall area of Namaqualand and SW Namibia, succulents such as the numerous species of Mesembryanthemaceae and Fabaceae form an important part of their diet. At Augrabies Falls, South Africa, George (1981b) found that 55–90% of the diet consisted of monocotyledons, even though the water content (57% in green grass and 18% in dry grass blades and stalks) was lower than in dicotyledons (75%). At Tumasberg, stomach contents ($n = 13$) contained seeds (3%), leaves (24.8%), stems (49.7%) and insect remains (21.0%) (Withers 1979). In the Erongo Mts of Namibia, Nokis consumed 28 species of plants (green leaves and stems, flowers, fruits, dry stems and leaves, according to the plant species). The diet changed seasonally depending on the phenology of each species (Rathbun & Rathbun 2005). Some species of plants were avoided, probably because of the presence of secondary defence compounds. The diet of Nokis is very flexible and varies from locality to locality depending on the plant species available.

Nokis have a simple typical rodent-like stomach and a large caecum. Cellulose-rich food is most likely to be fermented by micro-organisms in the intestine. Coetzee (1983) recorded 'jack-knife' movements of the head and body whereby food is regurgitated and rechewed, but Rathbun & Rathbun (2005) and Mess & Ade (2005) did not record such movements nor regurgitation. Leaf remains in stomachs vary from fresh and green fragments of ca. 2 mm (e.g. *Boscia albitrunca* and *Lycium* spp.) to those the size of sand-grains. Nokis are coprophagous; two sorts of faecal pellets are produced: dark, dry, brown ones and wet softer greenish ones. The greenish ones are often eaten, but the dry ones are not (Mess & Ade 2005). The two main longitudinal ridges in the proximal colon result in two distinct grooves, which separate the contents of the caecum. Coprophagy is likely to be an important method of increasing digestive efficiency, especially when the diet is coarse and fibrous.

Social and Reproductive Behaviour Socially monogamous (Rathbun & Rathbun 2006a). Lives in family groups that vary in size from one ♂, one ♀ and one young (Rathbun & Rathbun 2006a) to five animals (in an overnight shelter). Occasionally groups are larger, e.g. 22 animals from (presumably) two family groups, which were using granite boulders as overnight abodes (Coetzee 2002, unpubl.). A family group may congregate and rest on a rock or in shelters. Allogrooming takes place throughout the day, but self-grooming in the morning is more common. Grooming and suckling of young takes place at these resting sites. Young frequently bask and nap curled up on the extended front limbs ('lap resting'), or on top of the extended base of the tail ('tail resting'), of one of the parents (Rathbun & Rathbun 2006a).

The mean home-range of a male–female pair (95% minimum convex polygon) for five pairs of individuals in the Erongo Mts is 0.34 ha for ♀♀ and 0.23 ha for ♂♂ (Rathbun & Rathbun 2006a). The home-range of ♂ had a 56% overlap (on average) with that of ♀, and the home-range of ♀ had an 81% overlap (on average) with

that of ♂. There was virtually no overlap in the home-ranges of adjacent pairs. Male home-ranges (territories) are exclusive and are maintained by male–male aggression; ♀♀ are more tolerant and will allow intruding ♂♂ and other ♀♀ into their home-range. Home-ranges of both ♂♂ and ♀♀ contract greatly after the birth of the young, especially during the first week, when one parent, either ♂ or ♀, remains with the young nearly all the time. Rathbun & Rathbun (2006a) suggest that 'mate-guarding' is the principal adaptive factor in the evolution of social monogamy in Nokis (as it is for Kirk's Dik-dik *Madoqua kirkii* [Brotherton & Rhodes 1996] and Eastern Rock Sengi *Elephantulus myurus* [Ribble & Perrin 2005]).

Adults occasionally make soft 'tjijrrrrrr' squeaks whilst resting and at night; each squeak lasts for ca. 1.5 seconds and is repeated in a series (e.g. 13 squeaks in 90 seconds). The interval between series varies considerably (Coetzee 2002).

Reproduction and Population Structure In the winter rainfall area of SW Namibia and Namaqualand, reproduction is mainly during spring. In the summer rainfall areas of Namibia and Angola, fecund ♀♀ were mostly recorded during Sep to Apr (spring to autumn) with a peak in the autumn months. Gestation: ca. 12 weeks (Mess 2005). Litter-size: 1.97 ± 0.7 (1–3, $n = 37$). At birth, young weigh ca. 14.7 g (range 10.5–20 g; Coetzee 2002), precocial with eyes and ear pinnae open, fully furred and able to jump over their mother when ca. 10 minutes old (C. G. Coetzee unpubl.); first eat solid food on Day 14; weaned ca. Day 20 when 3–4 times birth-weight; adult weight (ca. 150 g) at 9–12 months (Coetzee 2002).

Predators, Parasites and Diseases Important mammal predators probably include: *Felis lybica*, *Galerella sanguinea*, *Galerella pulverulenta*, *Cynictis penicillata*, *Canis mesomelas* and *Vulpes chama*. Predation by *Galerella nigrata* is well documented (Rathbun & Rathbun 2006a). Snake predators may include *Python anchietae*, *Pseudapsis cana*, *Naja nigricollis*, *Naja haja*, *Bitis arietans* and *B. caudalis* (at the base of mountains). Captive *Petromus* react strongly to overhead movements. Raptors that are possible predators are *Falco biarmicus*, *Hieraaetus spilogaster*, *Aquila verreauxi*, *Cicaetus cinereus* and *Cicaetus pectoralis* (H. Berry pers. comm.). There are few records of parasites: ectoparasites include one cosmopolitan flea (*Echignophaga gallinacea*) (De Meillon *et al.* 1961) and endoparasites include a nematode worm (*Acanthoxyuris shortridgei*) (Monnig 1931, in De Graaff 1981). Not known to play any role in the spread of diseases.

Conservation IUCN Category: Least Concern.

Conserved in several nature reserves and national parks in South Africa, Namibia and Angola.

Family THRYONOMYIDAE

CANE RATS

Thryonomyidae Pocock, 1922. Proc. Zool. Soc. Lond. 1922: 423.

| | | |
|------------------------|-----------|--------|
| Thryonomys (2 species) | Cane Rats | p. 686 |
|------------------------|-----------|--------|

The family Thryonomyidae is endemic to Africa and contains a single genus distributed widely in the savanna regions throughout the continent. Cane rats are characterized by their large size (second only to *Hystrix* spp. and *Pedetes*), long coarse hairs, massive blunt head, short limbs and a rather short tail. Each foot has three well-developed digits (Digits 2, 3 and 4), ending in thick claws; Digits 1 and 5 are short or rudimentary and without a claw. The skull is easily recognizable by its large size, strong build and wide upper incisor teeth, orange in colour, each with three deep longitudinal grooves on the outer face (a character not seen in any other African rodent), well-developed supraoccipital crests, small auditory bullae, long finger-like paraoccipital process and thick zygomatic arches. There is a large infraorbital foramen

Figure 112. Skull and mandible of *Thryonomys swinderianus* (RMCA RG 22.827).

as in the other hystricomorph rodents (Figure 112). Dental formula: $I^{1/1}, C^{0/0}, P^{1/1}, M^{3/3} = 20$. The deciduous premolar is retained throughout life so there are always four cheekteeth. The molar teeth have an intricate pattern of enamel and dentine. The basic design is three transverse ridges; each upper molar has two infoldings on the outer (labial) side and one infolding on the inner (lingual) side (Figure 108), and each lower molar has one infolding on the outer side and two on the inner side. This design of alternating ridges of enamel and dentine results in very efficient mastication of the fibrous plant material in the diet. Size categories of species in the family (based on mean head and body length) are given in the order Rodentia profile.

Both species live in long grass savanna, swamps and reed-beds, and normally rest during the day in the dense grasses. They do not make proper nests and do not dig burrows. They are mostly nocturnal, although they may be active during the day in some situations. They tend to live in small groups and have a wide repertoire of calls and behaviours for communication between individuals. Cane rats are strict herbivores that feed primarily on coarse grasses, but they also feed on crops in agricultural areas. Because of their large size and succulent flesh, they are hunted by humans in many parts of their geographic range.

The Thryonomyidae is thought to be closely related to the Petromuridae (which contains just a single extant species, *Petromus typicus*). Some authorities place *P. typicus* within the Thryonomyidae, but here, following Woods (1993) and Woods & Kirkpatrick (2005), the two families are maintained. The geological record of the Thryonomyidae is sparse; fossils are known from the Oligocene of N Africa, and the Pleistocene of Niger, Sudan and Namibia (De Graaff 1981, Woods 1984), suggesting a wider distribution in the past than at the present time.

Thomas (1922) proposed the ‘*Choeromys* group’ for the cane rats of central and eastern Africa (*gregorianus*, *logonensis*), thereby separating them from the ‘*Thryonomys* group’ of western Africa (*swinderianus*). The ‘groups’ were differentiated primarily on overall size, the amount of inflation of the skull, the position of the grooves on the incisor teeth and the length of the tail. These differences are no longer considered of any value at the generic or subgeneric level (Rosevear 1969), although they are of value for identification at the species level.

The family contains a single genus with two species, *T. gregorianus* and *T. swinderianus*.

D. C. D. Happold

Genus *Thryonomys*
Cane Rats

Thryonomys Fitzinger, 1867. Sitzb. Akad. Wiss. Wein 56 (1): 141. Type species: *Aulacodus swinderianus* Temminck, 1827.

Thryonomys swinderianus.

Thryonomys sp.

The genus contains two species (Table 47) and is widely distributed throughout sub-Saharan Africa. Both species live in grassland habitats, especially where the grass is thick and lush. Characters of the genus are given in the family profile above. The two species are distinguished by body size, shape of frontal bone, position of grooves on the upper incisor teeth and length of tail.

D. C. D. Happold

Frontal view of incisor teeth of *Thryonomys gregorianus* (top) and *T. swinderianus* (below). (From Kindgon 1974)

Table 47. Characters of *Thryonomys swinderianus* and *Thryonomys gregorianus*.

| Character | <i>T. swinderianus</i> | <i>T. gregorianus</i> |
|--------------------------------------|---|---|
| Tail length ^a | 170–262 mm, at least twice as long as HF; longer than in <i>T. gregorianus</i> | 90 (65–173) mm, about equal to, or slightly longer than, HF; shorter than in <i>T. swinderianus</i> |
| Grooves on upper incisor tooth | Three grooves; outermost in mid-line of tooth; two inner grooves faint and close together | Three grooves; outermost nearer to outer edge than to mid-line; two inner grooves clearly separated |
| Skull size and shape | Arched in frontal region when viewed from side | More or less flat when viewed from side |
| Height of skull | ca. 44 mm | ca. 34 mm |
| Shape of zygomatic arch ^b | Zygomatic arch slopes outwards from top of head | Zygomatic arch slopes almost perpendicularly from top of head |
| Zygomatic width | 53–60 mm | 49–60 mm |
| Weight ^b | 3.2–5.2 kg (♂ ♂)
3.4–3.8 kg (♀ ♀) | 1.4–2.38 kg (♂ ♂)
1.7–1.9 kg (♀ ♀) |

^aTail length, and tail length relative to hindfoot (HF) length, appear to be good distinguishing characters in East Africa (Kindgon 1974), although not in southern Africa (Smithers 1983).

^bSouthern Africa (Smithers 1983).

Thryonomys gregorianus LESSER CANE RAT (LESSER GRASS CUTTER)

Fr. Petit Aulacode ; Ger. Kleine Rohrratte

Thryonomys gregorianus (Thomas, 1894). Ann. Mag. Nat. Hist., ser. 6, 13: 202. Kiroyo, Luiji Reru River, Kenya (00° 3'5 S, 36° 05' E).

Taxonomy Originally described in the genus *Aulacodus*. Thomas (1922) proposed that *T. gregorianus* should be placed in a separate genus, *Choeromys*, because of supposed differences between it and *T. swinderianus*. This proposal is no longer accepted. Rosevear (1969) recognized *T. longonensis* (from N Cameroon) and *T. camerunensis* (from S Cameroon) as species within the 'Choeromys group'. Synonyms: *camerunensis*, *congius*, *harrisoni*, *logonensis*, *pusillus*, *rutschuricus*, *sclateri*. Subspecies: none recognized here. Meester *et al.* (1986) listed two subspecies, *T. g. gregorianus* and *T. g. sclateri*, without giving reasons, and they were unable to comment on the validity of other taxa as subspecies. Chromosome number: not known.

Description Extremely large rodent (although smaller than *Hystrix* spp. and *T. swinderianus*), with large blunt head and coarse dense brownish pelage. Similar in form and colour to *T. swinderianus* (see description), although smaller. Tail short (ca. 38% of HB) and 2.5 times the length of HF. Skull strongly built. Upper incisor teeth broad (total width: 10–12 mm), orange on outer surface, each with three longitudinal well-separated grooves, the outer groove nearer to the outside than to the mid-line. Frontal region relatively flat when viewed from the side. Zygomatic arch slopes almost perpendicularly downwards from top of head. Cheekteeth with complex folds; each tooth with two folds on outer surface and one fold on inner surface. Cheekteeth cant outwards. M³ erupts well after other cheekteeth are in use. Well-developed supraoccipital crest and paraoccipital processes. Some ♂♂ tend to be heavier than ♀♀. Nipples: 0 + 2 = 4 placed laterally (Ansell 1966).

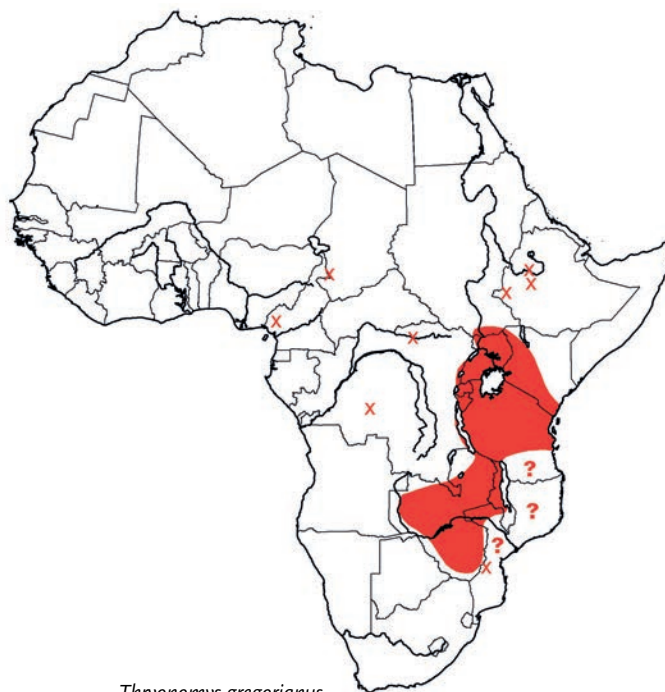

Geographic Variation Specimens from the northern part of the geographic range have a shorter tail and on average longer hindfoot compared with specimens from the southern part (see Measurements), e.g. four individuals from Kenya and E DR Congo have the following body measurements: T: 100 (90–112) mm, HF: 85 (74–92) mm.

Similar Species

T. swinderianus. Larger and heavier; tail at least twice length of HF; more extensive geographic range; including western and southern Africa.

Distribution Endemic to Africa. Parts of Zambezan Woodland Savanna BZ, Eastern Rainforest–Savanna Mosaic and southern part of Somalia–Masai Bushland BZ. Widely distributed in tall grass savanna in S Sudan, Uganda, Kenya, Tanzania, Zambia, Malawi and Zimbabwe. Isolated populations in Cameroon, DR Congo and Ethiopia. Likely to occur in Mozambique, but no definite records available.

Habitat Grasslands, tussock grasslands, swamps and rocky habitats in savanna habitats. Prefers drier habitats than *T. swinderianus*. Maybe be semi-aquatic at the edges of swamps.

*Thryonomys gregorianus*

Abundance Uncertain. Appears to be less common than *T. swinderianus*.

Adaptations Probably similar to *G. swinderianus*. Well-defined paths are made in long grass, often forming 'tunnels' (10–12 cm wide and 15–18 cm high) overhung by vegetation (Rahm & Christiaensen 1963).

Foraging and Food Herbivorous. In E DR Congo, Lesser Cane Rats feed on the stems of many sorts of plants, including the grasses *Pennisetum*, *Hyparrhenia*, *Setaria*, *Melinis* and *Exothea*, bracken *Pteridium* and wild ginger *Aframomum* (Rahm & Christiaensen 1963). In cultivated areas, feeds on cassava, stems of maize and sugarcane. Cane rats (both species) practise coprophagy, which occurs at a set time, usually between 08:00h and 11:00h, when faecal pellets are taken directly from the anus and reingested (Ewer 1969). It is assumed that coprophagy allows additional nutrients, including vitamins produced by the bacterial fauna of the caecum, to be absorbed during a second passage through the gut in much the same way as in species of Lagomorpha.

Social and Reproductive Behaviour Probably similar to Greater Cane Rats. Home-range in E DR Congo estimated to be 3000–4000 m² (Rahm & Christiaensen 1963).

Reproduction and Population Structure Information is sparse and inconclusive. In Uganda, one pregnancy recorded in Aug (two embryos; Delany 1975); in Kenya, pregnancies in Nov and Dec

(two ♀♀, three embryos each; Hollister 1919, as *T. pusillus*); in Zimbabwe, pregnancies in May (one ♀, two embryos) and Nov (one ♀, three embryos) (Smithers & Wilson 1979).

Predators, Parasites and Diseases Predators include Leopards *Panthera pardus*, Servals *Leptailurus serval*, pythons, viverrids and some eagles (De Graaff 1981). In Zimbabwe, preyed upon by Cape Eagle-owls *Bubo capensis* (Gargett & Grobler in De Graaff 1981). Humans hunt Lesser Cane Rats but they are not as important as a source of protein as Greater Cane Rats.

Conservation IUCN Category: Least Concern.

Thryonomys swinderianus GREATER CANE RAT (CUTTING-GRASS, GRASS CUTTER)

Fr. Grand Aulacode ; Ger. Grosse Rohrratte

Thryonomys swinderianus (Temminck, 1827). Monogr. Mamm. 1: 248. Sierra Leone (exact locality not stated).

Taxonomy Originally described in the genus *Aulacodus*. Synonyms: *angolae*, *calamophagus*, *logani*, *raptorum*, *semipalmatus*, *variegatus*. Subspecies: none currently recognized. Thomas (1922) recognized four forms based on colour, size and geography, all of which are now regarded as synonyms. Within West Africa, Thomas (1922) referred to the savanna race as *swinderianus* and the forest race as *raptorum*. Chromosome number: 2n = 44, NF = 86 (Benin; Civitelli *et al.* 1996).

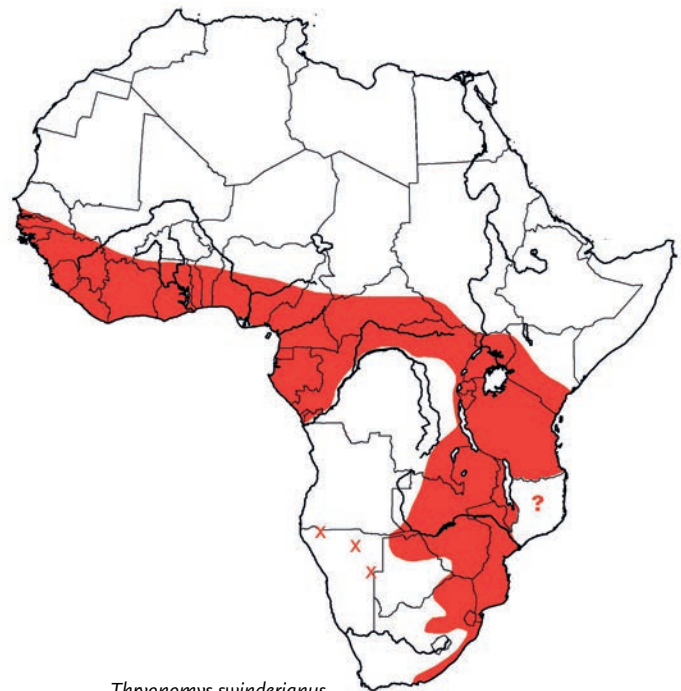

Description Extremely large rodent (surpassed only in size by *Hystrix* spp. and *Pedetes* spp.), with large blunt head and coarse dense brownish pelage. Dorsal pelage deep brown to rufous-brown, flecked with yellow and black. Dorsal hairs thick and coarse, mostly brown, with yellowish terminal band and (usually) black tip. Flanks similar to dorsal pelage merging into greyish-white ventral pelage. Body thickset. Head blunt with broad flattened muzzle; eyes small; mouth situated ventrally, set back from the enlarged nasal region; ears short and rounded, with short hairs and often partly obscured by cheek hairs. Limbs short and strong with well-developed claws. Forefeet with five digits: Digit 1 short, Digit 5 rudimentary. Hindfeet with four digits: Digit 1 absent, Digit 5 very small. Tail short (ca. 36% of HB and about twice the length of HF); thick at base tapering to tip; densely covered with short bristles similar in colour to dorsal pelage. Skull strongly built. Upper incisor teeth broad, orange on outer surface, each with three longitudinal grooves, the outermost groove in midline of tooth. Frontal region arched when viewed from the side. Zygomatic arch slopes outwards from top of head. Cheekteeth with complex folds; each tooth with two folds on outer surface and one fold on inner surface. Cheekteeth cant outwards. M³ erupts well after other cheekteeth are in use. Well-developed supraoccipital crest and paraoccipital processes. Males tend to be heavier than ♀♀. Nipples: 0 + 3 = 6, placed laterally.

Geographic Variation Colour variations associated with different geographic regions have been named as different forms (see Taxonomy).

Similar Species

Thryonomys gregorianus. Smaller and less heavy; tail about same length as HF; restricted to parts of central and eastern Africa.

Distribution Widely but patchily distributed in several savanna biotic zones south of the Sahara. May also occur, in smaller numbers, in grassy regrowth areas on the fringes of the Rainforest BZ. Rarely

Thryonomys swinderianus

recorded north of about 15°N in the north-west of the continent, north of 5–10°N in the north-east, or south of ca. 25°S except in some eastern coastal regions of South Africa. Not present in rainforests of central Africa, nor in arid habitats of Angola, Namibia, Botswana and South Africa.

Habitat Swamps, reed-beds, semi-aquatic habitats and long grass savannas where grass cover is dense. Also occurs in habitats subject to seasonal flooding, and in fields of sugarcane, maize and guinea corn.

Abundance Probably common in suitable habitats, although rarely seen. The large number killed for bushmeat (see below) suggests that Greater Cane Rats are very common in some regions. The commonest evidence of cane rats is the piles of droppings and the characteristic cut stems of grasses.

Adaptations Nocturnal, although may be active during the day in sheltered environments and on dull days. Although Greater Cane Rats have short limbs, they run quickly when disturbed, often 'freezing' after running for some distance. They make runways through dense grasses and reeds, and are good swimmers. During the day, an individual rests in a 'form', a simple depression in the grass often lined with cut grass stems (in much the same way as a hare), and occasionally in a rock crevice or burrow excavated by a large mammal. Eyesight is not particularly good, but hearing is very acute. Greater Cane Rats produce several vocal sounds, each of which is emitted as a specific communication signal to other individuals: the 'boom', sometimes accompanied by thumping with the hindfeet, is a warning signal when there is disturbance or potential danger; the 'growl' is a threat signal used during agonistic behaviour and sometimes by ♂♂ during courtship; the 'wheet' is a contact call by young, the 'squeak' indicates fear and may also indicate appeasement, and the 'quirr' is probably for close-contact communication with other Greater Cane Rats (Cox 1978). Each of these vocalizations may vary in emphasis, duration, repetition and amplitude depending on the motivation of the animal and the context in which each is given. The diversity of methods of communication suggests that Greater Cane Rats have a well-defined social organization (Cox 1978).

Greater Cane Rats are coprophagous (as are many Lagomorphs and *T. gregorianus*), and the caecum is enlarged and used for fermentation of food. These characteristics enable them to feed on grasses and stems with a high fibre content. In the dry season, when grasses are dead and particularly high in fibre, cane rats adapt by increasing the size of the caecum and colon, and the rate of coprophagy. Even though the daily intake of food is increased, protein intake and the rate of growth is reduced (van Zyl *et al.* 1999). The ability of these cane rats to extract nutrients from low quality fibrous food enables them to survive when only coarse dry grass is available.

The four cheekteeth in each ramus of the jaw erupt sequentially, and the age of an individual (up to about nine months when half adult weight) can be determined by the number of cheekteeth visible above the gum. From birth to ca. one month, only one tooth (P4) is visible; from 1 to 5 months only P4 and M1, from 5 to 9 months only P4, M1 and M2, and from nine months onwards all cheekteeth (P4, M1, M2 and M3) are present (van der Merwe 2000). The width of the cheekteeth and length of the toothrow in relation to

length of the skull is comparatively greater than in most other rodents – a condition related to the fibrous nature of the diet.

Foraging and Food Herbivorous; feeds primarily on the stems of thick coarse grasses and reeds. Greater Cane Rats have a unique way of cutting thick stems: the side of the head is placed along the length of the stem, but rotated so that the outer edge of the incisor teeth touches the stem. In this way, the incisor teeth bite at an angle of about 45 degrees to the long axis of the stem. The fallen piece of stem is then picked up in the mouth, grasped on either side of the mouth and sliced through the middle with the incisors. The two cut ends, each held in a forefoot, are fed into the mouth and sliced into small pieces by the incisors. Short bouts of incisor slicing are alternated with bouts of cheekteeth chewing, with a predominantly sideways action (Ewer 1969). The seed heads of grasses are eaten in a different manner: the stem is held in a forefoot and then pulled through the mouth stripping off the seeds. In cultivated areas, cane rats will feed on sugarcane, maize and guinea corn. A pile of short grass stems, cut at 45 degree angles, is a good indication of where a Greater Cane Rat has been feeding. They produce characteristically shaped faecal pellets, often where they have been feeding.

Social and Reproductive Behaviour Greater Cane Rats are normally encountered in small groups, although some groups may be large (e.g. 15 individuals seen together in Guinea; Gautun *et al.* 1986). Little is known about the composition of groups. In captivity (Ewer 1969), observations suggest that the social unit is single ♂ with one or two ♀♀ and their young. Greater Cane Rats exhibit many social interactions with conspecifics. Males determine their dominance by nose-pushing. Two ♂♂ approach each other, and when their noses touch, they push against each other. One of them may, alternatively, attempt to push against the cheek of his opponent, temporarily knocking him off-balance. If one individual relaxes for a moment, the other quickly flips round and tries to knock his opponent on the rump with his rump. These nose-pushes and rump-pushes continue until the loser jumps away and flees. The opponents do not attempt to bite with their incisors during these contests, nor do they threaten by gnashing their teeth (as do many species of rodents) (Ewer 1969).

Mutual grooming occurs between members of a group. An individual solicits grooming by turning the head so the throat is exposed. When two members approach each other and display in this manner, mutual grooming may commence. Grooming of the throat appears to be especially pleasurable (and, incidentally, is an area which the animal cannot groom by itself).

The tail is used to express submission. Wagging the tail from side to side appears to inhibit aggression by the individual to whom the signal is made. Youngsters have been observed to wag the tail when approached by an adult from behind, and ♂♂ wag their tails when courting ♀♀ (Ewer 1969).

Female suckles her young while lying on her belly, taking some of the weight of her body on fore- and hindlimbs. The lateral position of the nipples allow the young to suck from either side.

Reproduction and Population Structure Reproductive activity varies according to locality and climate. In Ghana, pregnancies occur in all months. In S Ghana, monthly pregnancy rate was 64–

93% ($n = 523$), with >80% during 10 months of the year, and in N Ghana, pregnancy rate was 26–95%, with >80% during the four months of the wet season (May–Aug) (Asibey 1974b). No information available on months when young are born, but seasonality of birth rate is probably related to seasonality of rainfall and grass growth. Information from elsewhere is inconclusive: young recorded in Jun and Aug in Botswana (Smithers 1971), and in Aug and Nov in Zimbabwe but information is lacking for other months (Smithers & Wilson 1979). Gestation 155 days (137–172), $n = 33$ litters (Asibey 1974b). Postpartum oestrus likely. Embryo number: 3 (1–5); $n = 18$ females (South Africa; van der Merwe 1999); 3.8 (2–5), $n = 6$ litters (van der Merwe & van Zyl 2001); 4–6, mode 4, $n = 480$ litters (Ghana; Asibey 1974b). Some evidence of embryo reabsorption (Asibey 1974b). Mean weight of young at birth: 128 (75–190) g ($n = 9$ litters). Total litter weight at birth is ca. 15–20% of maternal weight ($n = 112$ litters), and there is no relationship between litter weight and weight of the mother (Asibey 1981). Great variation in weight of young within and between litters. Mean litter-size varies according to age of mother: 3.1 for primiparous ♀♀ and 3.9 for parous mothers (Asibey 1974b). At birth, young are fully furred with eyes open, and can follow the mother within an hour of birth. In captivity, growth rates and adult weights greater for ♀♀ than for ♂♂; ♀♀ reach adult size at ca. Day 300, and ♂♂ at ca. Day 390 (van der Merwe & van Zyl 2001). Sexual maturity is attained at about seven months and a ♀ gives birth to her first litter when about one year old. Females probably produce two litters each year (Booth 1960, Asibey 1974b). In captivity, in South Africa, ♀♀ may have two litters per year (van der Merwe & van Zyl 2001). Histological changes during the oestrous cycle are described by Adjanohoun (1992). Longevity up to four years in captivity.

Predators, Parasites and Diseases Leopards, servals, hunting dogs, eagles, eagle-owls and pythons are potential natural predators (De Graaff 1981). Greater Cane Rats are vigorously hunted by humans

Thryonomys gregorianus.

because of their succulent flesh. Carcasses are seen for sale as 'bushmeat' in many parts of Africa, especially in the Rainforest BZ (see also *Atherurus africanus*). Greater Cane Rats are hunted with dogs and by burning savanna grasses, and are caught by snares. In Bendel State, S Nigeria, carcasses of cane rats formed 20–34% of all bushmeat for sale, and were either the most abundant or second most abundant species in local markets (Martin 1983, Anadu *et al.* 1988). In Accra, Ghana, about 110,000 kg of Greater Cane Rats were traded during a 12-month period in 1970–71 (Asibey 1974a) – equivalent to 40,000–55,000 individuals. In less suitable habitats, e.g. Equatorial Guinea, they form only a small proportion of 'bushmeat' (Juste *et al.* 1995). The meat of Greater Cane Rats has a higher percentage of protein and less fat per unit weight than does rabbit and chicken, and is also rich in calcium and phosphorus (Jori *et al.* 1995). Because of the desirability of these animals for food, studies in several African countries are investigating the possibility of domesticating and farming them commercially (Ajayi & Tewe 1980, Hardouin 1995, Jori *et al.* 1995).

Many species of ticks have been recorded (De Graaff 1981, Aeshlimann 1967), as well as gastrointestinal cestode and nematode worms (De Graaff 1981).

Conservation IUCN Category: Least Concern.

In spite of the very high hunting pressure on Greater Cane Rats, in some parts of the geographic range, numbers do not appear to be threatened at present. However, there is some evidence that population numbers are falling near large urban centres.

Measurements

Thryonomys swinderianus

Family MYOCASTORIDAE

COYPU

Myocastoridae Ameghino, 1904. *Anales Soc. Cient. Argentina* 56–58: 103.

This family of South American aquatic rodents contains only a single genus and single species, *Myocastor coypus*. The family belongs to the suborder Hystricomorpha (together with the African endemic families Bathyergidae, Hystricidae, Petromyidae and Thryonomyidae). This species is not indigenous to Africa, and only one introduced

population (now feral) is known to exist in Africa; therefore details of the family and genus are not given here (see Woods *et al.* 1992 [and references therein] and Woods & Kirkpatrick [2005] for further details).

D. C. D. Happold

Genus *Myocastor*

Coypu

Myocaster Kerr, 1792. In: Linnaeus, *Anim. Kingdom*, p. 23. Type species: *Mus coypus* Molina, 1782.

The genus is monotypic. Further information is given in the family and species profiles.

Myocastor coypus COYPU (NUTRIA)

Fr. Ragondin; Ger. Nutria

Myocastor coypus (Molina, 1782). *Sagg. Stor. Nat. Chile*, p. 287. Bio Maipo, Chile.

Taxonomy No information available for African populations. See Woods & Kirkpatrick (2005) for details of synonyms and subspecies in natural geographic range of species. Unless otherwise stated, this profile refers to the introduced population in Kenya – the only feral population known on the African continent. Synonyms: eight (world-wide). Subspecies: none in Africa. Chromosome number: $2n = 42$, $FN = 76$.

Description Extremely large shaggy rodent with dark lustrous pelage, long tail and webbed hindfeet. Pelage thick with long coarse guard hairs (dull or shiny) and dense underfur. Dorsal pelage brown, tending to blackish-brown in some individuals; guard hairs thin and long (up to 50 mm), pale or dark brown, usually with pale brown band(s) below tip. Ventral pelage similar to dorsal pelage in colour and texture. Underfur dark brown to black; dense and woolly. Head broad and thickset, similar in colour to dorsal pelage; muzzle and chin with some hairs pale or white or with white tip. Vibrissae very long and coarse. Ears dark, small and rounded. Fore- and hindlimbs short with dark brown or black hairs. Forefeet with five digits; Digit 1 short, Digits 2–5 long, each with long claw and without webbing between digits. Hindfeet long with webbing (skin) between digits, especially between Digits 1–2, 2–3 and 3–4; long claw on all digits. Tail short to long (ca. 72% of HB), with scales, sparsely covered with short dark brown hairs. Skull large and strong; zygomatic arches deep; infraorbital foramen very large; large pointed paraoccipital processes; mandible deep with angular process extending far posteriorly to condylar process and paraoccipital process; dental formula: $I\ 1/1$, $C\ 0/0$, $P\ 1/1$, $M\ 3/3 = 20$; incisor teeth smooth, without grooves, usually orange in colour on outer surface; cheekteeth flattened, converge anteriorly and camber outwards; each cheektooth with complex foldings of dentine and enamel on outer and inner surfaces (Figure 113). Nipples: 4–5 pairs situated dorsolaterally.

Figure 113. Skull and mandible of *Myocastor coypus* (BMNH 60.1948).

Geographic Variation None recorded in Africa.

Similar Species

Thryonomys swinderianus. HB of similar size, but shorter T (mean 183–188 mm); without webbing on hindfeet; smaller skull (GLS, GWS and P^4-M^3); terrestrial or semi-aquatic.

Thryonomys gregorianus. Smaller in size (mean HB: ca. 375 mm), with much shorter tail (mean 132–144 mm; ca 38% of HB); without webbing on hindfeet; skull smaller; terrestrial or semi-aquatic.

Distribution Introduced. In Africa, recorded only from aquatic habitats in C Kenya. Introduced (as captive animals) at Nanyuki in ca. 1947 (see also below). Later (ca. 1950), some animals were released (or escaped) and gradually spread throughout rivers, dams and swamps of the Central Highlands east of the Rift Valley (Ian Parker in litt.), as well into the Rift Valley at L. Naivasha (ca. 1960). They have been recorded, at various times, from the Ewaso Nyiro and Ewaso Narok rivers on the Laikipia Plateau, Ol Pejeta Conservancy and Mt Kenya Safari Club near Nanyuki, the Ark waterhole in the eastern Aberdare Ranges, near Sagana (possibly), L. Naivasha, L. Ol-Bolosat and near Kiserian (south of Nairobi) (data from many local sources). They have not been recorded from the alkaline lakes Elmenteita and Nakuru in the Rift Valley. Nor, as yet, have they been recorded from the highlands west of the Rift Valley (where the climate is similar to that east of the valley) and where they might be expected to occur. Map not given.

De Vos (1965) recorded that ‘coypu have been established in the wild in Zambia’ (see also Haltenorth & Diller [1980], Lever [1985] and Long [2003]). However, Ansell (1978), commenting on De Vos’ statement, wrote: ‘I am unaware of the basis for this assertion, but even if correct no more appears to have been heard of them.’ Local sources (in litt. 2005/2006) state that there is no evidence for the presence of coypu in Zambia. Haltenorth & Diller (1980) record that ‘from 1960 [coypu] has gone feral in the coastal swamps of Tanzania’ (see their map showing small range in the extreme NE corner of the country). Lever (1985) and Long (2003), both following Haltenorth and Diller (1980), also record the presence of Coypu in Tanzania. However, local sources (2005, with records back to the 1960s) have no knowledge of Coypu in Tanzania. On the basis of the present evidence, it appears that Coypu do not occur in the wild in Zambia or Tanzania. Lever (1985) records, without detail, that Coypu have been farmed in Zimbabwe and South Africa, and have not become feral in these countries. Other authors have also commented on the presence of Coypu in southern Africa. Aliev (1967) records Coypu in Botswana and Zimbabwe (as dots on a map) without comment or reference, and Carter & Leonard (2002) show the presence of Coypu in Zambia, Zimbabwe and Botswana (map, mostly following Aliev 1967) but also comment (as pers. comm. J. du Toit) that the species is not feral anywhere in southern Africa. Local sources in Zimbabwe and South Africa (M. van der Merwe, F. P. D. Cotterill, D. Spears pers. comm. 2007) record that the species is not present (farmed or feral) in these countries. The overall evidence suggests that, at the present time, Coypu are feral only in Kenya.

The natural distribution of the species is South America, but it has been widely introduced into North America, Europe and N Asia (Lever 1985, Long 2003, Woods & Kilpatrick 2005). (Map not given.)

Habitat Rivers, lakes, streams and swamps. Coypu are able to disperse from one aquatic habitat to another when conditions are favourable.

Abundance In Kenya, distribution is patchy. Very numerous in some habitats, e.g. the rivers and dams on the Laikipia plateau (N. Gregory in litt.). One dam at Ol Pejeta Conservancy contained eight individuals (ca. 4/ha; Butynski pers. comm.). Presence and abundance varies seasonally and annually; local populations may become extinct, but recolonization of a habitat may occur when conditions are suitable.

Remarks Aquatic and nocturnal. There are no detailed studies on the species in Kenya; the following remarks refer to populations extralimital to Africa. The webbed hindfeet are adaptations for swimming, and the thick water-repellent pelage helps to maintain a more or less constant core body temperature, especially when the water is cool or cold. Other adaptations for aquatic life include the ability to stay submerged for at least 10 minutes, and to preferentially maintain blood flow, during a dive, to the brain and heart while restricting blood flow to the muscles, intestines and kidney. Vegetarian, feeding on a large variety of aquatic and terrestrial herbs, stems and roots. Often gregarious. Litter-size: usually 3–6 (1–12); young precocial at birth; weaned at Week 8; attain adult weight at ca. 16–18 months (Britain; Southern 1964); maximum longevity in the wild probably 5–6 years. See Woods *et al.* (1992) for a review.

Conservation IUCN Category: Least Concern (worldwide).

Introduced into Kenya to provide pelts (skins) for making coats (see above). Population numbers in Kenya are kept in check by many predators (N. Gregory in litt.). Introduction of Coypu to L. Naivasha, together with the introduction of crayfish and Floating Water-fern *Salvinia molesta* in the 1960s and 1970s, has had dramatic adverse effects on the indigenous aquatic flora (Harper *et al.* 1990); additionally unwise water usage and inappropriate land management of the water catchment of the lake are having detrimental effects on the lake ecosystem. Geographic range is unlikely to expand in Kenya to any great extent because aquatic habitats in a cool climate are required for the survival of the species.

Order *LAGOMORPHA* – *Hares, Rock-hares, Rabbits and Pikas*

Lagomorpha Brandt, 1855.

| | | |
|----------------------------------|----------------------------|--------|
| Leporidae (5 genera, 13 species) | Hares, Rock-hares, Rabbits | p. 694 |
|----------------------------------|----------------------------|--------|

The order Lagomorpha contains two extant families (Leporidae, Ochotonidae), 13 extant genera and about 87 species (Hoffmann & Smith 2005). Of these, only the Leporidae, with five genera and 13 species, is represented in Africa. The order was once considered to be a suborder of rodents (because of the superficial similarity of the teeth). The modern view is that the Lagomorpha is an order in its own right. Based on molecular and morphological evidence, the Lagomorpha and Rodentia may be grouped together in the cohort Glires (see for example Scally *et al.* 2001, Bronner *et al.* 2003). The order is represented naturally in all continents except Antarctica, South America and Australia.

The principal characteristics of the order include: two pairs of upper incisors, the second pair being very small and located behind the first principal pair where they have no cutting function; incisor teeth which grow throughout life and are rooted in the premaxilla bone; no canine teeth; a diastema between the incisors and the cheekteeth (as in rodents and artiodactyls); five or six high-crowned cheekteeth (P¹, P², P³, M¹, M², M³), which may or may not have roots (depending on the family); large caecum; no baculum in the penis; and testes that are anterior to the penis. In size and habitat, members of the two families are rather different. Species of Leporidae are

the largest members of the order (details below), have long narrow upright ears, small fluffy tails, and live in grasslands and scrublands. In contrast, species of Ochotonidae (no longer present in Africa) are small (HB: ca. 125–300 mm, WT: 125–400 g), with small rounded ears close to the head, and most species are associated with rocks and talus (Nowak 1999). All members of the order are terrestrial and vegetarian.

The fossil record of the Lagomorpha in Africa is relatively poor and fragmentary (Cooke 1972). The earliest fossils, from the early Miocene (ca. 20 mya), are ochotonids from Kenya, Uganda, Namibia, Morocco and Libya (Erbajeva 1994, Winkler *et al.* 2005). It is assumed that these ochotonids arrived in Africa from Eurasia. The leporids are first known from Africa in the late Miocene (oldest is 6.5–6.6 mya) of Kenya (Winkler 2002, 2003; Mein & Pickford 2003) and Ethiopia (Haile-Selassie *et al.* 2004). From this time, leporids have radiated extensively (perhaps due to the expansion of grassland). Ochotonids are last known from Africa in the middle Miocene (14–15 mya; Mein & Pickford 2003, Winkler 2003) and now survive only in Eurasia and western North America.

The single family of the Lagomorpha in Africa is the Leporidae. Further details are given in the family profile below.

D. C. D. Happold

Family LEPORIDAE

HARES, ROCK-HARES AND RABBITS

Leporidae Fischer, 1817. Mém. Soc. Imp. Nat. Moscow, 5: 372.

| | | |
|--------------------------------|-----------------|--------|
| <i>Bunolagus</i> (1 species) | Riverine Rabbit | p. 696 |
| <i>Lepus</i> (6 species) | Hares | p. 698 |
| <i>Oryctolagus</i> (1 species) | Rabbit | p. 708 |
| <i>Poelagus</i> (1 species) | Bunyoro Rabbit | p. 710 |
| <i>Pronolagus</i> (4 species) | Rock-hares | p. 712 |

The family Leporidae occurs widely in the Palaearctic, Oriental and Ethiopian Regions, and certain species have been introduced into parts of South America, Australia and New Zealand, and many oceanic islands. Representatives of the family live in arctic, temperate semi-tropical, tropical, semi-arid and arid habitats. There are 11 genera and about 61 spp. in the family of which five genera and 13 species occur in Africa (see above); three of these genera are endemic to Africa (*Bunolagus*, *Poelagus*, *Pronolagus*). See Flux & Angermann (1990), Hoffmann (1993) and Hoffmann & Smith (2005) for further details.

Species in the Leporidae in Africa are easily recognized by their relatively large size for a ‘small mammal’ (mean HB: 300–600 mm, mean WT: 1–3 kg, according to species), which is larger than the majority of rodents, long (or very long) narrow ears, which project upwards from the head, large eyes, small fluffy tail and thick woolly pelage. Other distinguishing characters of the family include two patches of different-textured pelage – the nuchal patch on the back of the neck and the gular patch on the throat and anterior part of the chest, relatively long limbs (hindlimbs usually longer than forelimbs), four or five digits on each foot, and thick dense hairs on the soles of the feet. The skull is lightly built and arched with moderate restriction between the orbits, prominent supraorbital processes, well-developed thick zygomatic arches, maxilla bone with numerous

Figure 114. **Selected characters of the skull of Leporidae.** (a) upper front incisor teeth (frontal view) with deep groove filled with cement, (b) upper front incisor teeth (frontal view) with shallow groove not filled with cement, (c) cross-section of (a) above with the smaller second incisor posteriorly, (d) cross-section of (b) above with the smaller second incisor posteriorly, (e) ventral view of part of skull showing ‘minimum length of hard palate’ and ‘width of mesopterygoid space’. pf = palatal foramen, hp = hard palate, ms = mesopterygoid space, 1 = minimum length of hard palate, 2 = width of mesopterygoid space.

^a For genera with more than one species, values for the smallest and largest species are given.

^b Only *L. fagani* has a mean ear length of less than 100 mm, and the smallest values for T and HF.

fenestrae; a small hard palate (= bony palate, palatal bridge); and wide internal choanae (= mesopterygoid space). The skull is also notable for having two pairs of upper incisors, the secondary pair being very small and located behind the first principal pair where they have no cutting function; incisor teeth, which grow throughout life and are rooted in the premaxilla bone; no canine teeth; and well-developed diastema (as in rodents and artiodactyls). There are six high-crowned cheekteeth (P^1 , P^2 , P^3 , M^1 , M^2 , M^3) on each side of the skull and five on each side of the maxilla. The first tooth (P^1) of the upper cheekrow is smaller than the four succeeding teeth (P^2 , P^3 , M^1 , M^2), and the last tooth (M^3) is very small and sometimes missing (Figure 114). Dental formula: $I^{2/1}$, $C^{0/0}$, $P^{3/2}$, $M^{3/3}$ = 28. There is no baculum in the penis, and the testes are situated anteriorly to the penis.

Hares, rock-hares and rabbits are terrestrial, living in open, rocky, grassland or bushy habitats. They are primarily nocturnal, but may be active close to dawn and dusk on cool cloudy days. During the day, hares rest in 'forms' (small open nests in the grass), rock-hares rest in rocky crevices or under boulders, and rabbits hide in complex underground burrows (or 'warrens'), which they dig themselves. All species are noted for their fast quadrupedal running and manoeuvrability, and rock-hares are capable of jumping from rock to rock and running up steep rock faces. All leporids are herbivorous, grazing on short fresh grass and herbs. Digestion of plant tissue is notoriously difficult; in leporids, efficiency of digestion is enhanced by a very large caecum in the hindgut and by coprophagy (a process whereby faecal pellets are eaten and food passes twice through the digestive system).

Hares and rock-hares are solitary, and only occasionally seen in groups of up to three or four. In contrast, rabbits (particularly *Oryctolagus cuniculus*) are gregarious; several individuals share a burrow and may feed in small groups. Most species of hares and rock-hares have small litters, usually 1–3 young/litter; young are precocial at birth, fully furred with the eyes open, and capable of walking and running within a few hours. Rabbits have larger litters, up to 10–12/litter; young are altricial at birth, naked with the eyes closed, and they remain in the nest until 2–3 weeks of age.

The terms 'hare' and 'rabbit' are not clearly defined. However, 'hares' are usually larger than 'rabbits', have comparatively longer hindlimbs, are solitary, run with a fast loping gait, have small litters

and do not dig burrows. 'Rabbits' exhibit a converse set of characters. Some genera do not fit precisely into either 'hare' or 'rabbit' categories, and show a mixture of characteristics. Here, the term 'hare' is used for species that live in non-rocky habitats, do not dig burrows, have small litters and precocial young; 'rabbit' for species that live in non-rocky habitats, dig burrows, usually have large litters and altricial young; and 'rock-hares' for species that live in rocky habitats, do not dig burrows, have small litters and (probably) altricial young. One genus, *Polagus*, shows a mixture of hare and rabbit characteristics.

Taxonomic relationships within the family are uncertain, especially for the genus *Lepus*. Many specific names have been given to the hares of Africa, mainly because some have large geographic ranges and show great variation in colour, size and length of ear in different parts of their ranges. Historically each 'new' form was described as a new species. Current taxonomic methods have reduced the number of species of *Lepus* in Africa to six, some with many synonyms; however, there may be many 'cryptic species' within the species currently allocated to *Lepus*. Molecular analysis confirms that leporids are a monophyletic group (Robinson & Matthee 2005) and speciation into the major clades occurred 3–6 millions years ago. Within Africa, the alternating periods of wet and dry climates and the concomitant expansion and contraction of forests and savannas has been an important factor in leporid evolution.

The genera are distinguished by selected body and skull characters, chromosome number and geographic distribution (see Table 48). African hares and rabbits range in HB size from 368–432 mm (small), 433–496 mm (medium-sized) to 497–561 mm (large). Tail length ranges from 56–79 mm (short), 80–103 mm (medium-sized) to 104–127 mm (long). Ear length ranges from 65–90 mm (short), 91–115 mm (medium-sized) to 116–140 mm (long). Ear length relative to GLS ranges from 77–100% (relatively short), 101–123% (medium relative length) to 124–146% (relatively long). The ratio of the mean width of the mesopterygoid space to the mean minimum length of the hard palate (abbreviated to MS/HP) ranges from 52–84% (low), 85–117% (medium) to 118–149% (high). All of the above categories are based on means.

D. C. D. Happold

| MS/HP (as %) ^c | Chromosome number | Incisor teeth | Notes |
|---------------------------|-------------------|---|--|
| 80 | n.d. | Deep groove, no cement | Central Africa |
| 90 | 2n = 44 | Deep groove, no cement | North Africa (islands off South Africa) |
| 30–80 | 2n = 42 | Deep groove, no cement | Southern and eastern Africa |
| 150 | 2n = 44 | No cement | South Africa only. Dark stripe from mouth to base of ear |
| 100–150 | 2n = 48 | Deep groove, with cement (except <i>L. starki</i>) | Throughout Africa |

^c For MS = width of mesopterygoid space, HP = minimum length of hard palate (see Figure 114e).

GENUS *Bunolagus*

Riverine Rabbit

Bunolagus Thomas, 1929. Proc. Zool. Soc. Lond. 1929: 109. Type species: *Lepus monticularis* Thomas, 1903.

Bunolagus monticularis.

A monotypic genus occurring only in South Africa in bushy habitats close to streams and rivers. The genus is characterized by long ears (longer than in *Pronolagus*), a dark stripe on the lower jaw from near mouth to base of ear, soft silky hairs on soles of feet, uniformly coloured tail, and hard palate shorter than width of mesopterygoid space. *Bunolagus* exhibits significant difference in karyotype which separates it clearly from *Lepus* (Robinson & Skinner 1983): there are fewer chromosomes ($2n = 44$) than in *Lepus* ($2n = 48$). Of the species of Lagomorpha examined, this species has the most derived karyotype, differing from the hypothesized ancestor by seven fusions and five fissions (Robinson *et al.* 2002). Further details are given in the species profile.

D. C. D. Happold

Bunolagus monticularis RIVERINE RABBIT

Fr. Lapin des Boschimans; Ger. Flusskaninchen (Buschmannhase)

Bunolagus monticularis (Thomas, 1903). Ann. Mag. Nat. Hist., ser. 7, 11: 78. Deelfontain, Cape Colony, South Africa.

Taxonomy Originally described in the genus *Lepus*. Synonyms: none. No subspecies. Chromosome number: $2n = 44$ (Robinson & Skinner 1983).

Description Small dark rabbit with long ears. Pelage soft and fluffy. Dorsal pelage grizzled (agouti) blackish-brown, without rufous patch on rump; hairs grey at base, with white subterminal band and black tip. Flanks similar to dorsal pelage, becoming rufous on lower flanks. Ventral pelage white or pale rufous, usually confined to narrow band on mid-ventral line. Nuchal patch rich rufous. Head similar to dorsal pelage, with conspicuous white or pale buff eye-ring; white or buff colouration may extend anteriorly to nasal region. Thin brown or black stripe along lower jaw to base of ear. Ears comparatively and relatively long, broad, inner margin lined with white hairs, tips rounded and bordered by short black hairs on outer surface. Forelimbs similar colour to flanks; soles of forefeet with thick dense pale rufous hairs. Hindlimbs similar colour to flanks; hindfoot medium brown above, pale rufous-brown below; soles of forefeet with thick dense pale rufous hairs. Tail medium-sized, dark brown; hairs long and fluffy, slightly grizzled, without any white hairs. Skull characteristics include: GLS comparatively short; minimum length of hard palate comparatively short; MS/HP ratio high (ca. 147%); lacks antero-external shoulders on zygoma (cf. other African lagomorph genera); single groove on each principal upper incisor tooth not filled with cement (Figure 115, see also Table 48). Nipples: not known.

Geographic Variation None recorded.

Similar Species

Lepus capensis. Dorsal pelage grizzled, greyish, less fluffy; tail black above, white below; no black stripe on lower jaw; groove on each upper incisor filled with cement; grassy habitats.

Figure 115. Skull and mandible of *Bunolagus monticularis* (BMNH 2.12.1.26).

Bunolagus monticularis

Pronolagus spp. Pelage dense and harsh; tail uniformly rufous or rufous-black; ears relatively short or medium-sized; no black stripe on lower jaw; rocky habitats.

Distribution Endemic to Africa. South-West Arid (Karoo) BZ. Restricted to a small area in Northern and Western Cape Provinces, South Africa (Districts of Victoria West, Beaufort West Sutherland, Calvinia, Touws River and Frazerburg; additional details in Duthie *et al.* 1989).

Habitat Thick riverine bushland along seasonal rivers, especially where *Sasola glabrescens* and *Lycium* spp. predominate. In this habitat, grasses are uncommon and represent only about one-fifth of the cover provided by dicotyledonous plants (Duthie *et al.* 1989). The habitat is shared with Cape Hares (*Lepus capensis*).

Abundance Uncertain, but rare with a very small geographic range. Two censuses suggested densities of 0.064–0.166 individuals/ha, i.e. about one individual/6–15 ha. Extrapolation of these figures suggests that, in 1989, the remaining suitable habitat could not support more than ca. 1500 individuals (Duthie 1989, in Duthie & Robinson 1990), although the current population size is estimated to be less than 250 mature individuals (IUCN Red List 2004).

Adaptations Terrestrial and nocturnal. Constructs burrows with length of 200–300 mm, and entrance of 90–115 mm wide; nest chamber (120–170 mm wide) is formed at end of burrow. Burrow entrance plugged with soil and twigs when not in use. Locomotion rather slow compared with other leporids (Robinson 1981b).

Foraging and Food Herbivorous. Forages by browsing on flowers and leaves of dicotyledons, particularly *Pteronia erythrocaetha*, *Kochia pubescens*, *Salsola glabrescens*, *Rosenia humilis* and several species

of the Mesembryanthemaceae. Grasses are eaten only when available in the wet season (Duthie 1989, in Duthie & Robinson 1990).

Social and Reproductive Behaviour Solitary with a polygamous mating system. Mean home-range for ♂♂ is 20.9 ha and for ♀♀ is 12.9 ha; home-range of a ♂ can overlap with that of several ♀♀ (Duthie 1989, in Duthie & Robinson 1990). Young born in nest lined with fur and grass in a burrow, rather similar to that of the European Rabbit.

Reproduction and Population Structure Reproductive season extends from Aug to May during the warmer seasons of the year. Litter-size: one (occasionally two). Females may have a postpartum oestrus. At birth, young weigh ca. 40 g. Like other species of rabbits, the young are born altricial, blind and helpless at birth, and will only leave the burrow when old enough to look after themselves.

Predators, Parasites and Diseases Little information. Predators include African Wild Cats *Felis silvestris*, domestic dogs and Cape Eagle-owls *Bubo capensis*.

Conservation IUCN Category: Critically Endangered.

The rarest of all African lagomorphs, and the only African lagomorph placed in this IUCN category. Before 1948 was seen commonly, but in recent years has become increasingly rare (Robinson 1981b, Duthie *et al.* 1989). Much of the former range (never large) is now used for cultivation (Duthie & Robinson 1990). Rarity is presumed to be due mainly to habitat changes and a reduction in the area of suitable habitat; in addition, reduction in the numbers of jackals has resulted in an increase in the numbers of Wild Cats *Felis libyca* and Caracals *Felis caracal*, which prey on Riverine Rabbits (Robinson 1981b). The species is now the focus of various conservation programmes.

Lepus Linnaeus, 1758. Syst. Nat., 10th edn, 1: 57. Type species: *Lepus timidus* Linnaeus, 1758.

Lepus saxatilis.

The genus *Lepus* contains the largest number of species of any genus in the order Lagomorpha: about 32 spp. worldwide (Hoffmann & Smith 2005), six of these occurring in Africa. Members of the genus occur widely in arid, semi-arid and savanna habitats throughout the African continent. Two species (*Lepus capensis*, *L. victoriae*) have particularly large geographic ranges. Usually only one or two species occur in a single region (here often separated by habitat considerations), but three species are sympatric or syntopic on the Ethiopian Plateau and the Horn of Africa.

Species in the genus are characterized by their long limbs (especially the hindlimbs), their fast movement (the fastest of all

Figure 116. Skull and mandible of *Lepus victoriae* (RMCA 92-149-M-0010, as *Lepus crawshayi*).

Lepus capensis.

the lagomorphs) and their comparatively and relatively medium-sized to long ears (except comparatively short in *L. fageni*). Skull characteristics include: mean GLS > 87 mm (longer than other African lagomorphs except *Pronolagus crassicaudatus* and *P. randensis*); minimum length of hard palate short or medium-sized; MS/HP ratio high (except in *L. fageni*) as in *Bunolagus*; antero-external shoulders present on zygoma; single groove on each principal upper incisor tooth filled with cement (except *L. starki*, cf. all other African lagomorph genera) (Figure 116, Table 48). Species of *Lepus* live in open grassland and bushland habitats, and are not associated with rocks. They do not dig burrows. During the day they rest in ‘forms’ in the open, and they remain motionless to avoid detection. Young are precocial at birth, fully furred, the eyes are open, and they are capable of running within a few hours of birth. Hares are solitary, and associate with other hares only for courtship and mating, and when several congregate at highly favoured feeding areas.

The taxonomy of the genus is controversial (see also order profile). Species of the genus that have large geographic ranges show great variation in overall size, pelage colour and length of ear. The two particularly widespread species in Africa, *L. capensis* and *L. victoriae*, each have many synonyms, testimony to the large variation within each

species. Taxonomic uncertainties are exemplified by (a) some forms (now synonyms) that may be valid species, (b) currently recognized species that may in fact not be valid species, e.g. *L. habessinicus* may be a subspecies of *L. capensis* (Azzaroli-Puccetti 1987a, Flux & Angermann 1990), and (c) different viewpoints on what is the correct name for a species, e.g. *L. victoriae* (see Hoffmann 1993) is considered to be *L. microtis* by Hoffmann & Smith (2005) – although the name *microtis* is considered to be *nomina dubia* by Petter (1972c) because the holotype is a young animal. The genus is in need of revision. It is not possible to identify hares (or indeed lagomorphs in general) using only one or two characters; a combination of many characters, and ratios between selected measurements, are required for precise identification (Azzaroli-Puccetti 1987a, b). Chromosome numbers do not vary across the world range, but DNA analyses seem likely to resolve many taxonomic problems in the future (Alves *et al.* 2003).

The six species in the genus in Africa are distinguished by body size, ratio of width of mesopterygoid space to minimum length of hard palate, amount of black colouration on tip of ear, shape of groove on principal incisor tooth and presence/absence of cement in that groove.

D. C. D. Happold

Lepus capensis CAPE HARE

Fr. Lièvre du Cap; Ger. Kap-Hase

Lepus capensis Linnaeus, 1758. Syst. Nat., 10th edn, 1: 58. ‘ad Cap. b. Spei’ (Cape of Good Hope, South Africa).

Taxonomy Specimens of this species from Kenya are almost identical to those of *L. victoriae* where the two species are parapatric or sympatric (Flux & Flux 1983, as *L. crawshayi*). A similar situation occurs in Somalia where some specimens have been difficult to identify and appear to exhibit characters intermediate between the two species (Azzaroli-Puccetti 1987a). Because of its widespread distribution and inter-population variation, many forms of *L. capensis* have been described; these were originally given species rank but are now considered to be synonyms even though some of them may yet prove to be valid species (Flux & Angermann 1990). Synonyms: 38 African synonyms are listed by Hoffmann & Smith (2005), of which the following are considered by them to be subspecies: *aegyptius*, *aquilo*, *carpi*, *granti*, *hawkeri*, *isabellinus*, *sinaiticus*. The taxonomic limits of this species, and its relationships with *L. victoriae*, are uncertain, and require detailed investigation. Subspecies: none recognized here. Chromosome number: probably $2n = 48$ (Robinson 1981a).

Description Medium-sized. Pelage soft, not as ‘fluffy’ as in *Pronolagus* spp. and *Bunolagus*. Dorsal pelage silvery-grey, grizzled (agouti) with black; hairs white at base with wide black subterminal band, whitish terminal band, and black or white tip. Underfur white or greyish-white. Flanks similar to dorsal pelage, becoming very pale buff on lower flanks. Ventral pelage pure white; long. Head similar in colour to dorsal pelage. Lateral profile of head (from forehead to nasal region) distinctly angular (i.e. with obtuse bend downwards above the eye (cf. smoothly convex in *L. victoriae*) (Flux & Flux 1983). Eye-ring white, often with rufous markings above and below eye-ring. Cheeks greyish-brown. Upper lips pale rufous. Chin and throat white. Gular collar buffy-white or buffy. Ears relatively long (ca. 142% of GLS),

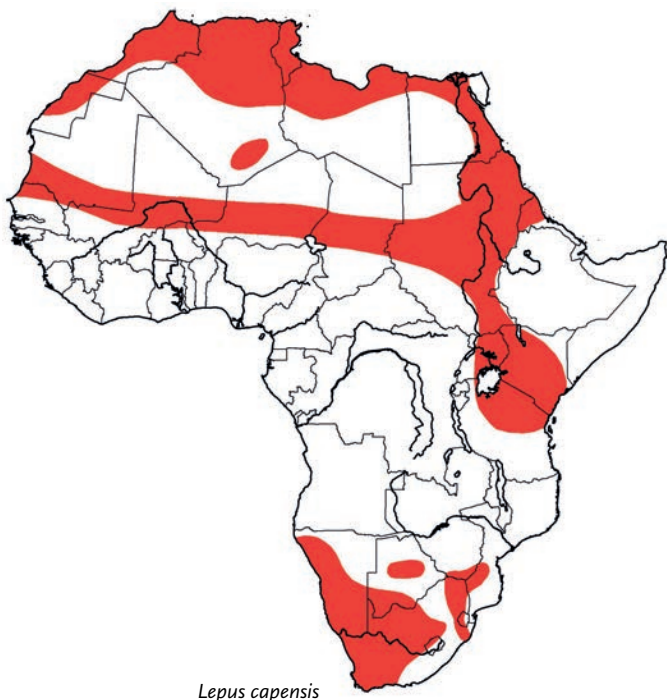

finely covered with buffy hairs; inner margin fringed with long white hairs; outer margin fringed with very short white hairs; tip of ear rounded, fringed with short black hairs especially on outer surface. Nuchal patch brownish-pink; rather inconspicuous. Forelimbs pale rufous above, white below. Hindlimbs pale rufous. Soles of all feet with buffy-brown hairs. Tail comparatively long, fluffy, black above, white laterally and below. MS/HP ratio high (ca. 140%). Each principal incisor tooth with small groove filled with cement.

Geographic Variation Pelage colour varies through range (and hence many synonyms). Individuals from arid and semi-arid habitats are paler in colour (dorsal pelage beige, oatmeal, with only a small amount of black speckling) than those from more mesic habitats (see Description above). Length of ear and hindfoot increase with increasing aridity of the habitat (see table below; BMNH):

| Form (n) | Locality | HF (mm) | E (mm) | Ratio E/HF % |
|------------------------|----------------|---------|---------|--------------|
| <i>aethiopicus</i> (5) | E Sudan | 80–102 | 110–118 | 114–132 |
| <i>hawkeri</i> (5) | W Sudan | 99–104 | 93–106 | 93–102 |
| <i>sefranus</i> (3) | Algeria | 99–110 | 100–112 | 91–113 |
| <i>whitakeri</i> (7) | Niger, Algeria | 95–114 | 117–135 | 114–127 |

Similar Species

L. victoriae. Dorsal pelage brown, grizzled with black; lateral profile of head smoothly convex; nuchal patch orange/brownish-orange; scrub, bush and grassland habitats.

L. saxatilis. Dorsal pelage grizzled dark buffy-brown; ears with narrow band of black on tip; nuchal patch large, pale rufous; soles of feet dark rufous; open and scrub habitats; southern Africa only.

Distribution Widespread in Mediterranean Coastal, Sahel Savanna and Somalia–Masai BZs, and several BZs in southern Africa. Recorded in two regions: (1) savanna and semi-desert regions of South Africa, Namibia, Botswana, S Zimbabwe, S Angola and S Zambia; (2) Kenya, Somalia and Ethiopia, and throughout much of the dry savanna regions of central, western and northern Africa, including parts of the Sahara Desert. Not present in rainforest habitats. There is a gap in distribution in eastern Africa (S Tanzania, Malawi, N Zimbabwe, parts of Mozambique). Extraliminally occurs throughout most of the Middle East and eastwards north of Himalaya Mts to China.

Habitat Grasslands and open habitats, including *Acacia* and *Brachystegia* savanna, Sahel and Sudan savanna, and semi-desert. Avoids bush habitats. Cape Hares are extremely adaptable and live in many environments. Prefer open habitats to closed habitats (cf. *L. victoriae*), and move into burnt areas when grasses begin to sprout. Hence, the range of Cape Hares has increased with bush clearance and extensive savanna fires (Flux & Flux 1983).

Abundance Probably the commonest lagomorph in Africa. Densities of 4.7–24.8 hares/km² have been recorded in South Africa (Wessels 1978 in Flux & Angermann 1990), and densities of 4.2 hares/km² (short grass habitats) to 9.2 hares/km² (long grass habitats) in Serengeti N. P., Tanzania (but see *L. victoriae* for further comments). Significantly fewer hares are observed with increasing number of larger mammals (Eltringham & Flux 1971).

Adaptations Terrestrial and nocturnal. During the day Cape Hares rest in ‘forms’ (as do other *Lepus* spp.) but may feed during the day when overcast. When disturbed, they run into the open (not

into cover as do *L. victoriae*) (Flux & Flux 1983). Cape Hares may be affected by larger mammals in the same way as *L. victoriae*, but detailed information is lacking. Cape Hares may assist dispersal of seeds for those species that have seeds with hooks or barbs. Agnew & Flux (1970) list 17 species of plants (mainly grasses) that have been found attached to the pelage of hares. The commonest seed was *Tragus berteronianus* (76% of seeds), followed by *Achyranthes aspera*, *Pupalia lapacea* and *Boerhavia repens* (all <1%). Only about half the hares examined carried seeds; for hares that carried seeds, the mean number of seeds/hare was 3.3 for ♀♀ and 1.2 for ♂♂; and rarely did any hare carry more than 20 seeds.

Foraging and Food Herbivorous. Grazes at night on grasses. Analysis of faecal pellets from dead specimens at Magadi (in the Rift Valley, Kenya) was dicotyledons 20%, grass (epidermis) 34%, sedge 2% and ‘stem fibres’ 35%. The principal grasses were *Sporobolus* sp., *Aristida* sp., *Chloris* sp., *C. dactylon*, *Enneapogon* sp. and *Eragrostis* sp. There were differences in the proportion of each grass species eaten at different sites, but seasonal differences in diet at each site were surprisingly small even though there were marked wet and dry seasons. It appears that hares are reasonably opportunistic, eating different grass species according to availability (Stewart 1971c).

Social and Reproductive Behaviour Mainly solitary; very occasionally in small groups. In Kenya, only four groups of three animals were encountered in 800 animals observed (Flux 1981b).

Reproduction and Population Structure Reproductive activity varies in different localities. In Kenya near the Equator, ♂♂ are fecund and ♀♀ are pregnant in all months (Flux 1969, 1981a). Pregnancy rate is 80–100% for most months of the year except in Apr (wettest month of the year) and Jun–Jul (end of wet season). Mean litter-size 1.5. Weight of young at birth: ca. 100 g. Number of litters/year: 6–8. Mean number of young/year: 11.6 (equivalent to 55% of adult female weight – a high percentage by lagomorph standards, but not as high as for *L. victoriae*). Mean litter-size varies seasonally: 1.0 in Sep to 1.9 in Jan, probably in response to changes in rainfall and forage. Litter-size also varies by altitude: hares at higher altitudes having smaller litters (mean 1.24 at 1800 m) than those at lower altitudes (mean 1.75 at 600 m). Growth rate of young hares: ca. 10 g/day. Adult size attained in 4–5 months (Flux & Jarvis 1970).

In Botswana, pregnant ♀♀ were found in Feb, Jun and Nov (only seven months sampled) but there are indications that hares continue to breed even in drought years (Smithers 1971). Litter-size: 1.9 (1–3); singletons 4, twins 6, triplets 3. See also *L. victoriae*.

Predators, Parasites and Diseases In Serengeti N. P., predators include Black-backed Jackals *Canis mesomelas*, Golden Jackals *Canis aureus*, Leopards *Panthera pardus*, Caracals *Caracal caracal* and Cheetahs *Acinonyx jubatus* as well as avian predators.

Conservation IUCN Category: Least Concern.

Widespread and common especially in reserved areas.

Lepus fagani ETHIOPIAN HARE

Fr. Lièvre éthiopien; Ger. Äthiopischer Hase

Lepus fagani Thomas, 1903. Proc. Zool. Soc. Lond. 1902 (2): 315 [1903]. Zegi, L. Tsana (= L. Tana), Ethiopia. 4000 ft (1220 m).

Taxonomy Taxonomic status uncertain; possibly a subspecies of either *L. victorae* or *L. capensis* (Flux & Angermann 1990). Considered to be closely related to *L. saxatilis* and *L. victorae*, and sometimes to be part of a *L. victorae*/*L. saxatilis* complex. However, Azzaroli-Puccetti (1987a) considered *fagani* to be a distinct species because its characters are unusually uniform throughout its geographic range. *Lepus fagani* is geographically isolated (on the mountains of Ethiopia north of the Rift Valley) from populations of *L. capensis* in the surrounding lowlands, and Flux & Angermann (1990) suggest that this probably resulted in the evolution of *L. fagani* as a distinct species. Following Azzaroli-Puccetti (1987a, b), Flux & Angermann (1990) and Hoffmann & Smith (2005), *L. fagani* is maintained here as a valid species. Synonyms: none. Chromosome number: probably 2n = 48 (as in all other *Lepus* spp.).

Description Large lagomorph with dense rather coarse pelage; dorsal hairs 20–25 mm. Dorsal pelage brownish-buff, finely grizzled (agouti) with black; hairs pale grey at base, white subterminal band, buff terminal band and (usually) black tip. Underfur whitish-grey. Flanks buff; hairs white at base, buff (not black) at tip. Ventral pelage white, fluffy. Head darker than dorsal pelage, blacker on crown. Chin and throat white. Ears comparatively short (cf. other Ethiopian hares – *L. habessinicus* and *L. starcki*) but of medium relative length (ca. 101% of GLS), buffy, with buff fringe on upper outer margin, white or buff fringe on lower outer margin; narrow black rim around inner surface of tip. Nuchal patch rich cinnamon-ginger extending on to sides of neck. Forelimbs cinnamon-brown; soles of forefeet with blackish-brown hairs. Hindlimbs brownish-buff above, white below; soles of hindfeet with blackish-brown or ginger-brown hairs. Tail medium-sized, fluffy, black above, buff at sides, buffy-white below. MS/HP ratio medium (ca. 99%). Each principal incisor tooth with deep simple groove entirely filled with cement; front face of each upper incisor tooth slopes laterally, thus forming an angled anterior surface.

Geographic Variation None recorded.

Similar Species

L. habessinicus. Dorsal pelage soft; ears longer; tail on average longer; Ethiopian plateaux and Horn of Africa.
L. starcki. Ears longer, upper quarter conspicuously black; tail longer;

principal upper incisor with groove not filled with cement; Ethiopian plateaux both sides of Rift Valley.

L. capensis. Pelage grizzled greyish; ears longer; nuchal patch brownish-pink, rather inconspicuous; open grasslands and semi-arid habitats; widespread.

Distribution Endemic to Africa. Afromontane–Afroalpine BZ of Ethiopia, and extending marginally into Sudan Savanna BZ. Recorded from the Ethiopian Plateau region west of the Rift Valley, mainly at 500–2500 m. Possibly also recorded from SE Sudan and extreme NW Kenya (Yalden *et al.* 2003; Flux & Angermann 1990; not mapped).

Habitat Scrub and forest margins; preferred habitat is less open than that of *L. habessinicus*, and similar to that preferred by *L. victorae* in Kenya (Yalden *et al.* 1986). ‘Wet grasslands with scattered thickets’ and ‘Bush cultivated area’ (labels, BMNH).

Lepus habessinicus ABYSSINIAN HARE

Fr. Lièvre d'Abyssinie; Ger. Abessinischer Hase

Lepus habessinicus Hemprich and Ehrenberg, 1832. Symbolae Puhsciae, Mamm., dec 2; sheet P, pl. 15, fig. 2. Near Arkiko, Ethiopia.

Taxonomy Status of this species uncertain; related to *L. capensis* (Azzaroli-Puccetti 1987b). Angermann (1983) and Hoffmann (1993) list *habessinicus* as a synonym of *L. capensis*. In contrast, Petter (1963a, 1972c), Yalden *et al.* (1986), Azzaroli-Puccetti (1987a, b) and Flux & Angermann (1990) consider *habessinicus* to be a valid species on account of its larger ears, well-developed interparietal bone, larger bullae and its isolation in the Horn of Africa. Flux & Angermann (1990) and Azzaroli-Puccetti (1987a), although recording *L. habessinicus* as a species, suggest that when other evidence is available, *habessinicus* may prove to be a subspecies or synonym of *L. capensis*. Because the evidence is still equivocal, Hoffmann & Smith (2005) retain *L. habessinicus* as a valid species. Synonyms: *abyssinicus*, *berberensis*, *cordeauxi*, *crispit*, *somaliensis*, *tigrensis*. Subspecies: none. Chromosome number: 2n = 48, aFN = 88 (as in all other *Lepus* spp.) (Azzaroli-Puccetti *et al.* 1996).

Description Medium-sized lagomorph with conspicuously long ears. Pelage soft and dense; dorsal hairs up to 20 mm. Dorsal pelage silvery-grey, grizzled (agouti) with varying amounts of black on shoulders, back and rump; dorsal hairs greyish-white at base, with broad black subterminal band, and buff or silvery-white terminal band, often with black tip. Grey underfur. Flanks paler; hairs pure white at base, subterminal band narrower than on dorsal pelage, whitish-buff at tip. Lower flanks very pale. Ventral pelage pure white, less dense than dorsal pelage; fluffy. Wide cinnamon or rufous stripe from forelimbs to hindlimbs separate ventral colour from flanks. Head similar in colour to dorsal pelage; nasal region and cheeks silvery-white, finely grizzled (agouti). Whitish eye-ring in some individuals. Chin grey or whitish. Ears relatively long (ca. 130% of GLS) and wide, brown or silvery-brown on outer surface, whitish-buff on inner surface; white fringe on lower part of outer margin; narrow black rim around tip of ear. Nuchal patch pale brownish-cinnamon, not extending laterally onto sides of neck. Forelimbs long, brownish-cinnamon above, pale whitish-buff below. Hindlimbs long, silvery-grey, grizzled (agouti) with black above, white or pale cinnamon-rufous below. Hindfeet cinnamon above and below. Soles of all feet with dense cinnamon hairs. Tail medium-sized, pure black above, pure white on sides and below. MS/HP

Lepus habessinicus

ratio high (ca. 125%). Each principal incisor with a deep groove entirely filled with cement.

Geographic Variation Pelage varies geographically: sandy-coloured in Eritrea, and greyer on Ethiopian plateau (*tigrensis*); probably related to soil colour (Yalden *et al.* 1986).

Similar Species

L. starki. Ears with upper quarter conspicuously black; principal upper incisor with groove not filled with cement; Ethiopian plateaux only.

L. fagani. Pelage coarse; ears shorter; Ethiopian plateaux.

L. victoriae. Dorsal pelage brown, grizzled with black; ears relatively shorter; ear tip black on inner and outer surfaces (amount of black variable); nuchal patch orange to brownish-orange; allopatric.

Distribution Endemic to Africa. Somalia–Masai Bushland BZ (and possibly some parts of Afroalpine–Afromontane BZ in Ethiopia). Recorded from E Ethiopia, Eritrea, Djibouti, N and C Somalia, and perhaps extreme NE Kenya. A record from Kamisa, Dinder R., E. Sudan mapped by Yalden *et al.* (1986) refers to a record by Setzer (1956) of *L. capensis dinderus* which they considered to represent *L. habessinicus*.

Habitat Desert and semi-desert from sea level to 2000 m; may extend up 2500 m on arid NE plateau of Ethiopia/Eritrea (Yalden *et al.* 1986).

Abundance Widespread, locally very common in Djibouti (Laurent & Laurent 2002).

Remarks Apparently no other information available.

Conservation IUCN Category: Least Concern.

Lepus saxatilis SCRUB HARE

Fr. Lièvre des buissons; Ger. Busch-Hase

Lepus saxatilis F. Cuvier, 1823. Dict. Sci. Nat. 26: 309. (Cape of Good Hope, South Africa.)

Taxonomy The taxonomic relationship between this species and *L. victorae* is uncertain. *Lepus saxatilis* and *L. victorae* are conventionally viewed as allopatric. Smithers (1983) considered *L. saxatilis* and *L. victorae* (as understood here) to be a single species, *L. saxatilis*, and therefore his distribution map for *L. saxatilis* combines the ranges of both species. Here, following Flux & Angermann (1990), Hoffmann (1993) and Hoffmann & Smith (2005), *L. saxatilis* is limited to the larger southern African form, and *L. victorae* to the smaller form to the north (Kryger *et al.* 2004).

Evidence from mtDNA suggests *L. saxatilis* comprises three lineages (Kryger *et al.* 2004). One lineage, long isolated and confined to SW South Africa (mainly Western Cape and Northern Cape Provinces), may be specifically distinct and is referred to here as *L. s. saxatilis*. The second lineage occurs in C and SE South Africa (mainly Eastern Cape and parts of Free State and KwaZulu–Natal Provinces) and the third lineage occurs in N South Africa, Namibia, Botswana and SW Zimbabwe. Together, these two lineages contain at least seven of the forms listed below as synonyms. For convenience, the second lineage is referred to here as *L. cf. saxatilis*. The third lineage is not referred to by any name in this profile, and its distribution is not included in the map. Synonyms of *L. saxatilis (sensu lato)*: *aurantii*, *bechuanae*, *chiversi*, *chobiensis*, *damarensis*, *fumigatus*, *gungunyanae*, *khanensis*, *longicaudatus*, *megalogotis*, *ngamiensis*, *nigrescens*, *orangensis*, *rufinucha*, *subrufus*, *timidus*. Subspecies: none recognized here. Chromosome number: probably 2n = 48 (as in other *Lepus* spp.).

Description *Lepus saxatilis* is medium to large with medium to long broad ears. Pelage soft. Dorsal pelage dark buffy-brown, grizzled (agouti) with black; hairs buff at base, with black subterminal band, buff terminal band and black tip. Underfur greyish-white. Flanks paler than dorsal pelage. Ventral pelage pure white. Pale buff band between

flanks and ventral pelage usually absent (cf. *L. capensis*). Head similar in colour to dorsal pelage. Grey or buff eye-ring, extending anteriorly to nasal region. Ears densely covered with small buffy-brown hairs; inner margin fringed with long buff hairs; outer margin fringed with very short white hairs; tip with narrow band of black on both inner and outer surfaces. Ears relatively long (ca. 139% of GLS in *L. s. saxatilis*) or of medium length (ca. 119% in *L. cf. saxatilis*). Nuchal patch large, pale rufous extending anteriorly under ears to base of head. Forelimbs brownish above, white below. Hindlimbs brownish-buff above, white below. Soles of all feet covered with thick dark rufous hair. Tail medium to long, black above, white below. MS/HP ratio high (ca. 149% in *L. s. saxatilis*; 123% in *L. cf. saxatilis*). Each principal incisor tooth with complex groove, filled with cement. (There is no consistent morphological or phenotypic distinction [other than greater size] to distinguish *Lepus s. saxatilis* from scrub hares in the more northerly parts of South Africa; T. J. Robinson, unpubl.)

Geographic Variation There is clinal variation in size within *L. saxatilis (sensu lato)*: *L. s. saxatilis* from the south-west of the range (Western Cape Province) are much larger than *L. cf. saxatilis* in the former Transvaal and KwaZulu–Natal Provinces of South Africa and further north in Zimbabwe. Measurements (mean and range) for ♂♂ from Western Cape Province, Transvaal and Zimbabwe (respectively) are: TL 558 (545–595) mm, 554 (450–640) mm, 529 (400–564) mm; ear: 140 (130–150) mm, 109 (95–148) mm, 99 (92–108) mm; weight: 3.19 (2.70–3.75) kg, 2.2 (1.4–2.9) kg, 2.04 (1.5–2.5) kg (various sources in Smithers 1983).

Similar Species

L. capensis. Dorsal pelage grizzled greyish; tip of ear fringed with short black hairs; nuchal patch brownish-pink, rather inconspicuous;

soles of feet buffy-brown; open grasslands and semi-arid habitats; widespread.

L. victoriae. Ear comparatively and relatively shorter (cf. *L. s. saxatilis*); nuchal patch orange to brownish-orange; soles of feet brown; scrub and bushland habitats; widespread.

Distribution Endemic to Africa. South-West Cape BZ (extending north and east into parts of South-West Arid BZ [mainly Karoo], Highveld BZ and Coastal Forest Mosaic BZ). *Lepus s. saxatilis* is endemic to SW South Africa (mainly Western Cape and Northern Cape Provinces). *Lepus* cf. *saxatilis* is widespread in C and N South Africa, eastwards to KwaZulu–Natal Province, Swaziland (Monadjem 1998a) and probably Lesotho (Lynch 1994). Records from some localities are dubious because it is difficult to distinguish this species from sympatric *L. capensis* in the field, and hence the northern boundary of the geographic range is very uncertain. Flux & Angermann (1990) place the northern limit of the range in C KwaZulu–Natal. However, Taylor (1998) and Kryger *et al.* (2004) refer to specimens of *L. saxatilis* from Zimbabwe and Botswana, implying the northern limit is in these countries (see also Taxonomy). Therefore the northern boundary of *L. saxatilis* (*sensu lato*) may be further north than shown in the map.

Habitat Occurs in a variety of open and scrub habitats. In KwaZulu–Natal, South Africa, recorded in open grasslands, thornveld and roadside verges (Taylor, 1998). In Namibia, prefers rocky and stony habitats, although also known from open sand-plain, bushveld and forest (Shortridge 1934). Attracted to cultivated areas and gardens.

Abundance Common in South Africa. No detailed information from elsewhere.

Adaptations Nocturnal. During the day, Scrub Hares rest singly in a 'form' in the grass or under a bush. When disturbed in the daytime, they run in a zig-zag fashion to the nearest cover. Sometimes

two hares will lie close together, but in different forms, and when disturbed, each runs in a different direction.

Foraging and Food Forages at night. Grazes on grass leaves, rhizomes and stems, with a preference for green grass (K. Collins pers. comm.).

Social and Reproductive Behaviour Solitary, occasionally in pairs.

Reproduction and Population Structure Pregnant ♀♀ recorded in Aug, Oct, Dec, Jun and Jul ($n = 15$) in South Africa, suggesting that reproduction occurs throughout most (if not all) of the year (Taylor 1998). Embryo number: 3.5 (1–4), $n = 15$ (KwaZulu–Natal; Taylor 1998). In Zimbabwe (as *L. saxatilis*, but may be *L. victoriae*), pregnant ♀♀ have been recorded in all months of the year, with peak in reproduction during the warmer months (Sep–Feb); embryo number 1.6 (1–3), $n = 25$ (Smithers & Wilson 1979).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

However, *Lepus s. saxatilis* is restricted to a small area of south-western South Africa, where habitats are highly modified by farming, and populations are subject to over-hunting. Consequently, these hares should be considered as 'rare'.

Lepus starcki ETHIOPIAN HIGHLAND HARE (STARCK'S HARE)

Fr. Lièvre des haut plateaux d'Éthiopie; Ger. Äthiopischer Hochland Hase

Lepus starcki Petter, 1963. Mammalia 27: 239. Jeldu Liban, Shoa, 40 km W Addis Ababa, Ethiopia. 2720 m.

Taxonomy Originally described as a subspecies of *L. capensis*, but raised to species rank by Angermann (1983). Azzaroli-Puccetti (1987a, b) also lists *L. starcki* as a valid species, but suggests that it may be a relict form of *L. europaeus* because of the similarity between their skulls; she suggests that after the retreat of glaciers during an inter-glacial period, populations of *L. europaeus* were isolated on the Ethiopian Plateau and evolved in isolation to the subspecific level, and therefore the name might be *L. europaeus starcki*. Hoffmann (1993) and Hoffmann & Smith (2005) follow Angermann (1983) in assigning *L. starcki* to specific rank. Synonyms: none. Chromosome number: 2n = 48 (as in all other *Lepus* spp.) (Azzaroli-Puccetti *et al.* 1996).

Description Medium-sized dark lagomorph, darker than *L. habessinicus*. Pelage thick and dense; dorsal hairs 20–25 mm. Dorsal pelage buffy-white, grizzled (agouti) with dots and streaks of black. Dorsal hairs whitish-grey at base, with wide black subterminal band, whitish terminal band and black tip. Underfur dense, grey or greyish-white. Flanks paler; hairs pale grey at base with broad white or buff subterminal band, and black or white tip. Lower flanks pale cinnamon-rufous; hairs white with cinnamon tip. Ventral pelage pure white, fluffy. Head similar in colour to back. White eye-ring in some

individuals. Ears of medium length (ca. 122% of GLS) with upper quarter conspicuously black on both surfaces; outer surface with wide fringe of white or buff hairs along inner margin, and narrow fringe of white hairs along outer margin, except at tip; in some individuals, the black extends along the outer margin of the outer surface, and on the inner margin of the inner surface, to base of ear. Chin whitish, with tinge of cinnamon on lips. Nuchal patch bright cinnamon or rufous, not extending onto sides of neck. Forelimbs long, pale cinnamon. Hindlimbs whitish-grey above, cinnamon and white below. Hindfeet cinnamon-buff above, medium-brown below. Soles of all feet with dense brown hairs. Tail medium-sized, pure black above, white on sides and below; tail colour variable – holotype has pure white tail. MS/HP ratio high (ca. 128%). Each principal upper incisor tooth with wide groove not filled with cement.

Geographic Variation None recorded.

Similar Species

- L. habessinicus*. Dorsal pelage grizzled silvery-grey; ears with narrow black rim around tip; nuchal patch pale brownish-cinnamon; Ethiopian Plateaux and Horn of Africa.
- L. fagani*. Pelage rather coarse; ears shorter with narrow black rim around inner surface of tip; nuchal patch rich cinnamon-tinger extending onto sides of neck; groove on each upper incisor filled with cement; Ethiopian plateaux west of Rift Valley.
- L. victoriae*. Dorsal pelage brown, grizzled with black; ears with much less black on tip; nuchal patch orange to brownish-orange; widespread but not recorded from Ethiopian plateaux.

Distribution Endemic to Africa. Afroalpine–Afromontane BZ of Ethiopia. Recorded only in restricted areas in the highlands, especially in the mountains of Arussi and Bale regions; 2500–4000 m. Does not occur in the Ethiopian Rift Valley separating these mountain regions.

Habitat Open highland habitats, especially grasslands and montane moorlands (Yalden *et al.* 1986).

Abundance Widely distributed within its restricted geographic range. In places, may be very common; e.g. Leslie Brown (in Flux & Angermann 1990) wrote: 'I have never seen so many [hares], even on some Scottish moors, as there are in the heath zone of the Arussi Mountains ... at over 11,000 ft.' Sympatric in part of range with *L. habessinicus* (Angermann 1983). Estimated densities 0.3/ha in afroalpine grasslands on Sanetti Plateau, 0.2/ha in *Helichrysum* scrub

Lepus starcki

at Tullu Deemtu, and 0.17/ha in grasslands of the Web valley in Bale (Sillero-Zubiri & Gottelli 1995).

Remarks One ♀ pregnant and one ♀ lactating in Dec. Embryo number: 1 (n = 1). Reproduction in the dry season would be expected at this altitude (D. W. Yalden, pers. comm.). Preyed on by Ethiopian Wolves *Canis simensis* (composing 1.6% of diet numerically but 11.6% by weight; Sillero-Zubiri & Gottelli 1995) and by Tawny Eagle *Aquila rapax* (L. Brown in Flux & Angermann 1990).

Conservation IUCN Category: Least Concern.

Lepus victoriae AFRICAN SAVANNA HARE

Fr. Lièvre des savanes; Ger. Afrikanischer Savannen Hase

Lepus victoriae Thomas, 1893. Ann. Mag. Nat. Hist., ser. 4, 12: 268. Nassa, Speke Gulf, L. Victoria, Tanzania.

Taxonomy The status of this species, and its various synonyms (including *crawshayi*, *canopus*, *whytei* and *zechi* which are widely used in the older literature) is debatable. The form *victoriae* was included with *L. saxatilis* by Robinson & Dippenaar (1987) and Smithers (1983). Petter (1972c) referred to this species as *L. whytei* and listed *victoriae* and *microtis*, amongst others, as *nomina dubia*. Subsequently, Angermann & Feiler (1988), Flux & Angermann (1990) and Hoffmann (1993) considered *L. victoriae* to be a valid species. However, Hoffmann & Smith (2005) refer to this species as *L. microtis*, on the basis that *microtis* Heuglin, 1865 predates *victoriae*. Some taxonomic confusion has arisen because the type skull of *victoriae* is missing (and its characters are unknown) and because the type of *whytei* seems to be aberrant and not 'typical' of others in nearby localities. Azzaroli-Puccetti (1987b) considers that *whytei* (from Malawi) is close to *L. fagani* (from Ethiopia), although distinguishable on cranial and dental characters, and that the wide geographic separation between the two forms merits recognition of *whytei* as a valid species. *Lepus victoriae* may be considered as the northern allospecies of the southern *L. saxatilis* (see *L. saxatilis*). Here, *L. victoriae* is maintained as a valid species. Synonyms: *angolensis*, *ansorgei*, *canopus*, *crawshayi*, *herero*, *kakumegae*, *mickleimi*, *microtis*, *meridionalis*, *raineyi*, *senegalensis*, *whytei*, *zairensis*, *zechi*, *zuluensis*. Subspecies: none. Chromosome number: probably 2n = 48 (as in all other *Lepus* spp.).

Description Based on *crawshayi* from Nigeria. Medium-sized brown lagomorph. Pelage soft but slightly coarse; dorsal hairs up to 20 mm. Dorsal pelage brown, grizzled (agouti) with black, but showing geographic variation; hairs whitish-grey at base, black subterminal band, yellow-buff terminal band, black at tip. Flanks buff, with fewer black-tipped hairs than dorsal pelage. Whitish-grey underfur. Crown of head and nasal region similar to dorsal pelage. Lips, cheeks and around eyes greyish, without black-tipped hairs. Ventral pelage white or buff. Chin white. Gular collar rufous or buffy. Lateral profile of head (from forehead to nasal region) shallowly and smoothly convex (cf. angular in *L. capensis*) (Flux & Flux 1983). Throat

buffy-brown. Ears of medium length (ca. 114% of GLS), brownish, grizzled (agouti), outer surface with wide fringe of white or buff hairs along inner margin, and narrow fringe of white hairs along outer margin, except at tip; tip black on both outer and inner surfaces, amount of black variable. Nuchal patch orange to brownish-orange. Forelimbs long, buffy-brown. Hindlimbs cinnamon-brown; hindfeet cinnamon-brown above, brown below. Soles of all feet with dense brown hairs. Tail medium-sized; black or dark brown above, white or off-white laterally and below. MS/HP ratio high (ca. 124%). Each principal incisor tooth with wide deep groove filled with cement.

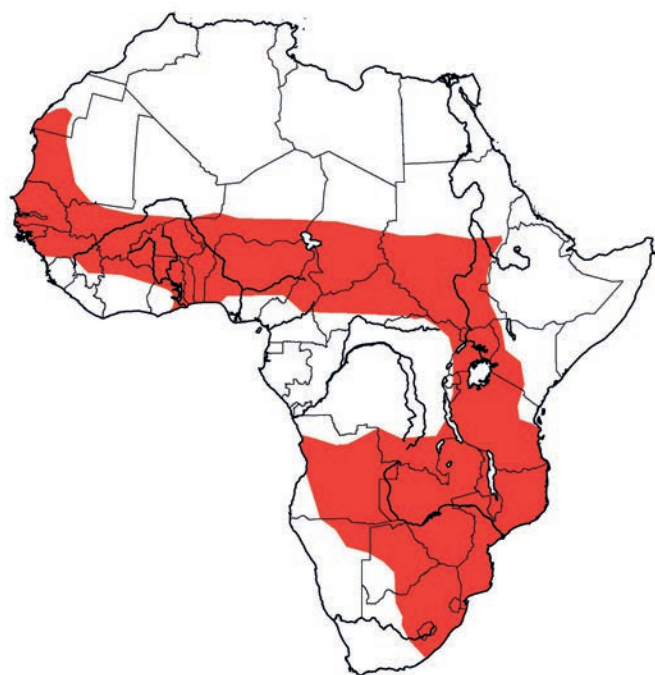

Geographic Variation Pelage colour varies geographically. Montane forms are more rufous and darker than lowland forms (Flux & Angermann 1990).

Similar Species

L. capensis. Dorsal pelage grizzled silvery-grey; nuchal patch brownish-pink, rather inconspicuous; lateral profile of head angular; grasslands, open habitats and semi-desert; widespread.

L. saxatilis. Dorsal pelage grizzled dark buffy-brown; nuchal patch large, pale rufous; soles of feet dark rufous; open and scrub habitats; southern Africa only.

Distribution Endemic to Africa. Sahel Savanna and Guinea Savanna BZs, Rainforest–Savanna Mosaics, Zambezian Woodland BZ and parts of the Somalia–Masai Bushland BZ. Widespread in savanna and semi-desert regions of Africa south of the Sahara, but not present in southern Africa where it is replaced by an allopatric species, *L. saxatilis*. Occurs in mountain regions up to about 3600 m on Mt Kenya (Flux & Flux 1983). A relict population (probably of this species) occurs near Beni Abbas, Algeria, in the Sahara Desert (Petter 1959a as *L. crawshayi*; Kowalski & Rzebik-Kowalska 1991 as *L. saxatilis*); the status of this population is uncertain and needs confirmation. Not present in rainforest habitats.

Lepus victoriae

Habitat Scrub, bush and grasslands habitats, preferring less open habitats compared with *L. capensis*. Also semi-arid grasslands.

Abundance Uncertain because it is difficult to distinguish this species from *L. capensis* in the field. For both species combined, Curry-Lindahl (1981) records biomass estimates that vary greatly according to habitat, e.g. 131 kg/km² in Tsavo N. P., Kenya; 182 kg/km² in Upemba N. P., DR Congo; 242 kg/km² in Serengeti N. P., Tanzania; and 362 kg/km² in Virungu N. P., DR Congo. For Serengeti N. P., this biomass is equivalent to ca 1.2 hares/ha (assuming mean wt of 2 kg/hare). Other estimates have given much lower densities of hares; for example, 8.5 hares/km² (= 0.09 hares/ha) in Serengeti N. P. (Frame & Wagner 1981). The characteristics of the habitat determine the density of hares: in Serengeti N. P., density ranged from a minimum of 0.4 hares/km² in short grass savanna to 3.1 hares/km² in *Themeda* savanna, 10.4 hares/km² in *Pennisetum* savanna and 18.6 hares/km² in medium-height grassland with >50% shrub cover (Frame & Wagner 1981). Numbers vary according to season of the year and habitat: in Queen Elizabeth N. P., Uganda, the number of hares seen during night counts ranged from 6.6 to 9.1 hares/km (annual mean 7.8 hares/km) in short grass/sparse thickets, to 0.6–2.3 hares/km (annual mean 1.4 hares/km) in short grass/dense thickets (Ogen-Odoi & Dilworth 1987). Hares are attracted to areas where grasses are sprouting after burning. Most estimates of density and biomass should be taken with caution because hares are difficult to census.

The numbers of hares remains relatively constant during each season, probably because they breed throughout the year (see below). In this respect, they differ markedly from some temperate species in the genus that exhibit marked annual and multi-annual fluctuations in numbers.

Adaptations Terrestrial and nocturnal. Normally run for cover when disturbed (cf. *L. capensis*) (Flux & Flux 1983). The number of hares may be partly determined by other species of mammals. Light to moderate grazing of grasslands by Common Hippopotami

Hippopotamus amphibius in Queen Elizabeth N. P., Uganda stimulates the growth of new sprouts, which, in turn, attract hares (Ogen-Odoi & Dilworth 1987). When numbers of large grazing mammals increase, the number of hares declines significantly (Eltringham & Flux 1971). The relationship between the numbers of larger mammals and hares is not clearcut; little is known about the responses of hares to each species of large mammal, or the role of large grazing mammals in modifying grasslands and how such modification may be beneficial or detrimental to hares.

Foraging and Food Herbivorous. In Kenya, identified species in the diet (as assessed by faecal analysis) were *Digitaria* sp. 19%, *Hyparrhenia* sp. 11%, *Cynodon dactylon* 4% and dicotyledonous epidermis 1.4%; nearly 50% of the diet was unidentified grass leaf epidermis, stems and grass fibres (Stewart 1971b).

Social and Reproductive Behaviour Mostly solitary; sometimes in groups of 2–3 while feeding. Home-range 5–10 ha (Flux & Angermann 1990).

Reproduction and Population Structure Reproduction occurs throughout the year in Kenya on the Equator, with all sampled ♀♀ being pregnant except in May and Nov when 80% of sampled ♀♀ were pregnant (Flux 1981a). Mean litter-size: 1.6. Weight of young at birth: ca. 100 g. Number of litters/year: 6–8. Mean number of young/year: 13.9 (equivalent to 68% of adult female weight – a very high percentage by lagomorph standards). This hare, like *L. capensis* in Kenya, is a good example of the reproductive strategy in a tropical hare near the Equator (i.e. long reproductive season, many litters/year, small number of young/litter and a high reproductive effort); such a strategy is possible because the environment (primarily rainfall and food resources) enables reproductive activity throughout the year (Flux 1981a). No information available from other localities.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern (as *L. microtis*).

GENUS *Oryctolagus*

European Rabbit

Oryctolagus Lilljeborg, 1873. Sverig. Og Norges Ryggradsdjur 1: 417. Type species: *Lepus cuniculus* Linnaeus, 1758.

Oryctolagus cuniculus.

A monotypic genus, widespread in Europe but confined in Africa to the extreme north-west of the continent and some islands off southern Africa. The genus is distinguished by its comparatively small body size, small hindfeet and short ears. Skull characteristics include: GLS short (shortest of all African lagomorphs); mean minimum length of hard palate short; MS/HP ratio medium (90%); antero-external shoulders present on zygoma; single groove on each principal upper incisor tooth not filled with cement (Figure 117, Table 48). The single species, *O. cuniculus*, is unique among African lagomorphs because it is a social species, constructs large subterranean burrows and has large litters. Other characteristics of the genus are given in the species profile.

Figure 117. Skull and mandible of *Oryctolagus cuniculus* (BMNH 19.17.7.2533).

D. C. D. Happold

Oryctolagus cuniculus EUROPEAN RABBIT

Fr. Lapin de garenne; Ger. Europäisches Wildkaninchen

Oryctolagus cuniculus (Linnaeus, 1758). Syst. Nat., 10th edn, 1: 58. 'in Europa australis' (= Germany).

Taxonomy Originally described in the genus *Lepus*. The European Rabbit has been rarely studied in Africa. Populations in Morocco and Algeria were probably introduced in the eighteenth century (Kowalski & Rzebik-Kowalska 1991). Loche (1867, in Kowalski & Rzebik-Kowalska 1991) referred to the Algerian Rabbit as *Cuniculus algirus*; more recent authors place *algirus* as a subspecies of *Oryctolagus cuniculus* on the basis of its smaller size. Populations on islands off the coast of South Africa (see below) are descended from domesticated strains of *O. cuniculus* first released in the 1650s (Smithers 1983). Synonyms: nine (all extralimital to Africa; Hoffmann 1993). Subspecies (Africa only): *algirus*. Chromosome number: $2n = 44$ (Schroder & Van der Loo 1979).

Description *Oryctolagus cuniculus algirus* is a small greyish-brown lagomorph, smaller than all other lagomorphs in Africa. Dorsal pelage pale brown, slightly flecked with black and buff; hairs ginger-

brown at base, buff terminally, sometimes with black tip. Underfur grey. Ventral pelage white tinged with pale ginger-buff; hairs white, some with ginger-buff tip. Head similar in colour to dorsal pelage. Chin and throat white. Eye-ring absent. Ears comparatively and relatively short (ca. 98% of GLS), dark brown, darker than dorsal pelage. Nuchal patch pale rufous-brown. Gular patch ginger-buff tinged with orange. Fore- and hindlimbs short (cf. *Lepus* spp.), pale brown. Hindfeet white above, soles thickly covered with pale brown hair. Tail short, same colour as dorsal pelage above, brown or white laterally, white below. Skull: see family and genus profile.

Geographic Variation Extraliminally, pelage colour varies geographically. Specimens from North Africa are paler than those from Spain. Domestic rabbits (and feral descendants) vary in colour from white to brown and black, with or without different colour patches.

Similar Species

Lepus capensis. Much larger in all measurements, ears comparatively and relatively much longer; each principal incisor tooth with groove filled with cement; widespread.

Distribution Mediterranean Coastal BZ. Recorded from N Morocco and N Algeria (coastal regions and Tell Atlas), but not further eastwards to Libya; also on Habibas Is (west of Oran, Algeria). Introduced in the 1600s on to several islands near the coast of South Africa and Namibia: currently present on Jutten, Schaapen, Vondeling, Dassen and Robben Islands near Cape Town, Bird I. near Port Elizabeth, and Possession I. near Luderitz (Smithers 1983, Lever 1985, Flux *et al.* 1990). (Distribution on these islands not shown on map.) Introduced to several other smaller islands near the South African coast, but now locally extinct. Extralimittally widespread throughout continental Europe (natural populations); introduced into Britain (probably in eleventh century), Australia, New Zealand and several South American countries, and many oceanic islands (Flux & Fullager 1983, Flux *et al.* 1990, Lever 1985).

Habitat High mountains, dense bushy regions, and arid habitats in Morocco (Aulagnier & Thévenot 1986). Tends to avoid forested habitats and open areas in Algeria (Kowalski & Rzebik-Kowalska 1991). Sometimes found in cultivated areas.

Abundance Common in W Algeria, less common in E Algeria (Kowalski & Rzebik-Kowalska 1991). Populations in Algeria were reduced when the disease myxomatosis was introduced.

Adaptations Mainly nocturnal, but active at dawn and dusk when conditions are suitable. Dig extensive underground burrows ('warrens') for resting in during the day, and for protection when threatened. Considered a pest in cultivated crops when population numbers are high. As for European Rabbits elsewhere, very adaptable

and prolific. Apart from North Africa, European Rabbits have not colonized Africa (as they have in other continents where they have been released); it seems that competition and predation have prevented individuals (whether introduced purposely, or escaped from captivity) from establishing permanent populations.

Foraging and Food Herbivorous. Graze on grasses. No detailed information for African populations.

Social and Reproductive Behaviour No information for North Africa, but likely to show similar behaviour to populations elsewhere. Social and territorial. A dominant ♂ associates with several ♀♀ and their young. When population numbers are low, groups are small; when high, social groups may defend territories but may join other groups to feed at night.

Reproduction and Population Structure No detailed information for North Africa. Elsewhere very prolific, with an ability to breed opportunistically when conditions are favourable. In general, the reproductive season is shorter at higher latitudes and longer at lower latitudes, and more opportunistic in drier arid habitats than in wetter temperate climates. No data on reproductive season in North Africa, but probably occurs during summer months (Apr–Sep) in Atlas Mts, and in spring and autumn (or even winter) on the semi-arid Mediterranean coast and opportunistic reproduction in summer when conditions are favourable. In North Africa, it is probable that reproductive data are similar to elsewhere in southern Europe (as given below). Young born in burrow, in nest of fur made by mother. Gestation: 28–30 days. Litter-size: 3–9, 4–6 or 3–4, depending on season and environmental conditions. Females have postpartum oestrus. At birth, young are altricial, naked, with eyes closed. Weaned ca. Day 20, when first leave nest. Maturity: 3–4 months. Population numbers fluctuate, often greatly. High productivity of young is matched by heavy predation by predators. Population numbers increase during the reproductive season and decline at other times of the year (Gibb 1990). The reproductive strategy of the European Rabbit contrasts greatly with that of hares (genus *Lepus*).

Predators, Parasites and Diseases Occasionally preyed on by owls, and hunted by humans in Algeria (Kowalski & Rzebik-Kowalska 1991). Probably has numerous other predators. The disease myxomatosis (caused by the virus *Myxoma*) has reduced population numbers in many parts of the world.

Conservation IUCN Category: Least Concern (worldwide).

Although common and widespread (and regarded as pests at times) in some continents, status in North Africa is not known.

Poelagus St Leger, 1932. Proc. Zool. Soc. Lond. 1932 (1): 119. Type species: *Lepus marjorita* St Leger, 1929.

Poelagus marjorita.

A monotypic genus distributed in savanna habitats in eastern and central Africa to the north of the Rainforest BZ. The genus lacks unique features (Corbet 1983). Like most *Lepus*, the body is medium-sized, individuals are mostly solitary, do not live in extensive underground burrows, and litters are small. As in *Oryctolagus*, the skeleton is not built for fast movement, the ears are comparatively and relatively short, and the young are altricial at birth. Skull characteristics include: GLS of medium length; minimum length of hard palate medium; MS/HP ratio low (ca. 84%) as in *Pronolagus*; antero-external shoulders present on zygoma; single groove on each principal upper incisor tooth not filled with cement (Figure 118, Table 48).

The mixture of characteristics suggest that the single species does not fit into any other genus of Lagomorpha, and that a separate genus, *Poelagus*, is warranted. Other characteristics of the genus are given in the species profile.

Poelagus marjorita BUNYORO RABBIT (UGANDA GRASS HARE)

Fr. Lapin sauvage d'Afrique centrale; Ger. Bunyoro-Buschkaninchen

Figure 118. Skull and mandible of *Poelagus marjorita* (RMCA no number).

Poelagus marjorita (St Leger, 1929). Ann. Mag. Nat. Hist., ser. 10, 4: 292. Near Masindi, Bunyoro, Uganda.

Taxonomy Originally described in the genus *Lepus*. Synonyms: *larkeni*, *oweni*. Subspecies: none. Chromosome number: not known.

Description Medium-sized lagomorph with comparatively

short ears. Dorsal pelage buffy-brown, grizzled (agouti) with black hairs; hairs whitish-grey at base, with wide black subterminal band, pale brown to buff terminal band, and black tip. Underfur greyish-white. Flanks paler, mainly buffy-brown; most hairs without black

tips. Ventral pelage yellowish-buff; hairs whitish-grey on basal half, yellowish-buff on terminal half. White mid-ventral stripe from chest (ca. 20–30 mm wide) to lower abdomen (ca. 40–50 mm wide), extending posteriorly on to inner surface of hindlimbs; hairs pure white. Ventral underfur pure white. Head similar in colour to dorsal pelage; chin and throat white. Ears comparatively and relatively short (ca. 77% of GLS), similar in colour to dorsal pelage, usually without fringe of white hair on ear margins; brown hairs on inner surface; no black on tip. Nuchal patch rufous, not extending on to sides of neck. Fore- and hindlimbs brownish-buff, soles of feet with dense rufous or blackish hairs. Tail short; same colour as dorsal pelage above and on sides, paler (often with some white hairs) below. Both sexes have glandular slits on either side of the genitalia. Juveniles with deep rufous nuchal patch; hairs on soles of feet whitish or grey. Skull: see family and genus profiles. Nipples: not known.

Geographic Variation None recorded.

Similar Species

L. victoriae. Tail longer; ear comparatively and relatively longer (ca. 114% of GLS); each principal incisor tooth with wide deep groove filled with cement; more widespread.

L. capensis. Dorsal pelage silvery-grey, grizzled with black; tail and hindfoot longer; ear comparatively and relatively longer (ca. 142% of GLS); each principal incisor tooth with wide deep groove filled with cement; more widespread.

Distribution Endemic to Africa. Eastern Rainforest–Savanna Mosaic and Guinea Savanna BZs. Recorded from C and W Uganda, S Sudan, NE DR Congo and NE Central African Republic. There is no evidence for the species in Ruanda, Burundi, Kenya, S Chad, S DR Congo and N Angola (*contra* Duthie & Robinson 1990 and Kingdon 1997) (see Happold & Wendelen 2006).

Habitat Primarily woodland savanna; also stony habitats and hills with short grass (Hatt 1940a). May also occur in forests (e.g. in S Sudan; Setzer 1956).

Abundance Uncertain. Reported to be common in open savanna scrub in S Sudan (Setzer 1956), and in Garamba N. P., DR Congo (Verheyen & Verschuren 1966). In Uganda, reported in 1928 as ‘Abundant in certain localities at night grazing on grassy tracks and roads’, and in 1958 as ‘Very common grazing by roads at night’ (labels, BMNH).

Adaptations Terrestrial and primarily nocturnal. During the day, rests alone in a form in thick vegetation. Locomotion is more similar to that of a rabbit than of a hare (Kingdon 1974). This is probably because the skeleton is rabbit-like, e.g. scapula is long and narrow (broad and ‘shovel-like’ in hares), ulna is sturdy (reduced in hares), transverse processes of lumbar vertebrae are narrow (expanded in hares) and cervical vertebrae are short (elongated in hares) (St Leger 1932); however, in some specimens, these characters are not so pronounced and are more similar to those of *Lepus* (Hatt 1940a).

Foraging and Food Forages at night on flowers and sprouting grasses. Tends to prefer pastures that have been heavily grazed by

Poelagus marjorita

larger mammals, newly mown fields and burnt areas where the grasses are sprouting (Kingdon 1974). Quantitative data on diet is not available.

Social and Reproductive Behaviour Probably solitary when resting in a form; feeds at night in small groups (pairs, or ♀♀ with young). May be found on rocky habitats with Rock Hyraxes (Kingdon 1974).

Reproduction and Population Structure Newborn young recorded in Jan, Feb, Mar, Jun, Aug and Oct in Garamba N. P., NE DR Congo (Hatt 1940a, Verheyen & Verschuren 1966), and juveniles (WT: 185–200 g) recorded in Jan, Feb, May and Aug (labels, RMCA) suggest that reproduction occurs in most (if not all) months of the year. One large embryo recorded in mid-Aug (Faradje, DR Congo; Hatt 1940a). Gestation thought to be about five weeks (Kingdon 1974). Litter-size: 1–2. Young born in short burrow, the entrance concealed by grass and soil (Kingdon 1974). At birth, young are blind and helpless, with sparse covering of short hair (as in *Oryctolagus cuniculus*).

Predators, Parasites and Diseases No detailed information, but likely to include Servals *Felis serval*, Genets *Genetta* spp., hawks and owls (Kingdon 1974). In Uganda, hunted with nets and dogs.

Conservation IUCN Category: Least Concern.

GENUS *Pronolagus* Rock-hares

Pronolagus Lyon, 1904. *Smithson. Misc. Coll.* 45:416. Type species: *Lepus crassicaudatus* I. Geoffroy, 1832.

Pronolagus rupestris.

The genus *Pronolagus* – the Rock-hares – contains three or four species that occur mainly in southern Africa. One species, *P. rupestris*, is also represented in eastern Africa, but its taxonomic status is uncertain. Rock-hares (unlike other lagomorphs) are always associated with rocky habitats. Diagnostic characters of the genus are medium to large size (as in most *Lepus* spp.), hindlimbs

that are only slightly longer than forelimbs (cf. *Lepus*), ears short to medium-sized, uniformly coloured rufous or rufous-black tail, and a considerable amount of reddish or rufous colouration on the limbs and ventral surface. Skull characters include: GLS short to medium-sized; minimum length of hard palate medium to long (depending on species); MS/HP ratio low; antero-external shoulders present on zygoma; and a single groove on each principal upper incisor tooth not filled with cement (Figure 119, Table 48) (cf. most *Lepus* spp.).

Rock-hares are unique in their ability to run and jump over rocks and boulders; they live in small colonies (perhaps because of restrictions in the extent of their habitat) and litter-size is small. Young are altricial at birth (like rabbits) and are born in a nest lined with fur.

Traditionally three species have been recognized (*P. crassicaudatus*, *P. randensis*, *P. rupestris*) (Hoffmann & Smith 2005). Here, the form *saundersiae* (listed as a synonym of *P. rupestris* by Hoffmann & Smith 2005) is also considered to be a valid species (Whiteford 1995, Matthee & Robinson 1996).

The species are mainly distinguished by the size of body, hindfoot and ear, geographic range and by selected ratios (see profiles).

D. C. D. Happold

Figure 119. Skull and mandible of *Pronolagus crassicaudatus* (RMCA RG2624).

Pronolagus crassicaudatus NATAL RED ROCK-HARE

Fr. Lièvre Roux du Natal; Ger. Natal-Rotkaninchen

Pronolagus crassicaudatus (I. Geoffroy, 1832). Mag. Zool. Paris 2: cl. 1, pl. 9. 'Port Natal' (= Durban South Africa).

Taxonomy Originally described in the genus *Lepus*. Formerly treated as a subspecies of *P. randensis* but now considered to be a valid species. Synonyms: *kariageae*, *lebombo*, *lebomboensis* (*lapsus*), *ruddi*. Subspecies: possibly five (see below). Chromosome number: $2n = 42$ (as in all *Pronolagus* spp.).

Description Large lagomorph with reddish-coloured limbs. Pelage rather dense and harsh. Dorsal pelage brown, grizzled (agouti) and flecked with black, becoming bright rufous on rump; hairs pale rufous at base, with cream subterminal band, black at tip. Underfur grey. Flanks paler than dorsal pelage, with fewer black-tipped hairs. Ventral pelage pale rufous, with irregular white patches and streaks; hairs mostly with white tips. Head greyish-brown, slightly grizzled. Chin, lower cheeks and throat grey or greyish-white; with greyish-white band extending laterally along edge of jaw to nuchal patch. Nuchal patch brown to grey. Gular patch brownish-rufous (contrasting with colour on throat and chest). Ears relatively short (ca. 81% of GLS) and sparsely furred; whitish-grey on outer surface, grey (similar to cheek) on inner surface. Fore- and hindlimbs dull rufous; soles of all feet rufous-brown. Tail short, bright rufous above and below (but not as dark or as black as in other *Pronolagus* spp.). MS/HP low (ca. 61%). Each principal incisor tooth with groove (close to inner margin of tooth) not filled with cement.

Geographic Variation Petter (1972c), Meester *et al.* (1986) and Flux & Angermann (1990) list five subspecies, but their status, characteristics and geographic limits are uncertain and their validity is doubtful. Listed here without comment: *P. c. crassicaudatus*, *P. c. ruddi*, *P. c. kariageae*, *P. c. bowkeri* (considered to be a subspecies of *P. rupestris* by Smithers 1983, Hoffmann & Smith 2005) and *P. c. lebombo*. Subspecies distinguished partly by colour of nuchal patch (see Taylor 1998).

Similar Species

P. saundersiae. HB on average shorter (mean 447 mm; ear shorter

(80–105 mm); tail on average longer (mean 86 mm); sympatric in part of range.

Distribution Endemic to Africa. Coastal Forest Mosaic, Highveld and parts of Afromontane–Afroalpine BZs in SE South Africa. Recorded from eastern South Africa (primarily KwaZulu–Natal and Mpumalanga Provinces), Lesotho, Swaziland and extreme S Mozambique (Meester *et al.* 1986, Duthie & Robinson 1990). Occurs from sea level to 1550 m. Syntopic in northern and eastern part of range with *P. saundersiae*. Distribution is patchy (see below). Two records from Mozambique (Smithers & Lobão Tello 1976) are not assignable.

Pronolagus crassicaudatus

Habitat Rocky kopjes, rocky hills and ravines where grasses and shrubs grow among the rocks or at base of rocks.

Abundance Relatively common and widespread in KwaZulu-Natal (Taylor, 1998). No detailed information from elsewhere.

Adaptations Nocturnal. During the day, hides in crevices in rocks and under boulders, or in forms in dense grass. Relies heavily on rocks and boulders for cover, and rarely moves far away from rocks when foraging. The skeleton is 'rabbit-like' since the hindlimbs are only slightly longer than the forelimbs. Droppings are deposited in middens, which are often far from resting sites (Duthie 1997).

Foraging and Food Herbivorous. No detailed information.

Social and Reproductive Behaviour Lives in small colonies consisting of a few individuals (Duthie 1997).

Reproduction and Population Structure In KwaZulu-Natal, pregnant ♀♀ have been recorded in Jun and Aug, and lactating ♀♀ in Aug, Oct and Feb (Taylor, 1998). These data suggest that reproduction occurs throughout much of the year. Embryo number: 1 (n = 1) or 2 (n = 3).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Pronolagus randensis JAMESON'S RED ROCK-HARE

Fr. Lièvre Roux de Jameson; Ger. Jamesons Rotkaninchen (Rand-Wollschwanzhase)

Pronolagus randensis Jameson, 1907. Ann. Mag. Nat. Hist., ser. 7, 20: 404. 'Observatory kopje', Johannesburg, South Africa. 5900 ft (1798 m).

Taxonomy Formerly included *P. crassicaudatus* as a subspecies. Synonyms: *capricornis*, *caucinus*, *ekmani*, *kaokoensis*, *kobosensis*, *maka-pani*, *powelli*, *waterbergensis*, *whitei*. Subspecies: none. Chromosome number: 2n = 42 (as in all *Pronolagus* spp.).

Description Medium-sized; brownish, with rufous limbs and rump. Pelage dense, woolly with silky texture. Dorsal pelage brown, grizzled (agouti), pale rufous on rump and flanks; hairs pale cinnamon at base, with white or cream subterminal band and often black tip. Usually darker on upper back due to many black-tipped hairs. Underfur rufous-brown. Flanks paler. Ventral pelage pale cinnamon, sometimes with white patches; hairs cinnamon with white tip. Head grizzled brownish-grey (without any rufous). Lower cheeks and throat whitish-grey. Ears short (ca. 93% of GLS); brownish-grey with white hairs at tip. Nuchal patch rufous. Gular patch brownish-rufous; hairs with white tips. Fore- and hindlimbs pale rufous, similar to flanks; soles of feet dark brown. Tail medium-sized; blackish-rufous, with black-tipped hairs especially towards tip. MS/HP ratio low (ca. 52%). Each principal incisor tooth with groove (close to inner margin of tooth) not filled with cement.

Geographic Variation A preliminary study of mtDNA collected from specimens from six South African localities reveals no geographic variation among populations representing four previously

recognized subspecies (*P. r. randensis*, *P. r. powelli*, *P. r. makapani* and *P. r. capricorni*) (Matthee 1993). Thus there is little geographic variation within the western *P. randensis* group as suggested by Meester *et al.* (1986), who recognized only two subspecies: *P. r. caucinus* (Namibia) and *P. r. randensis* (South Africa, Zimbabwe and Botswana).

Similar Species

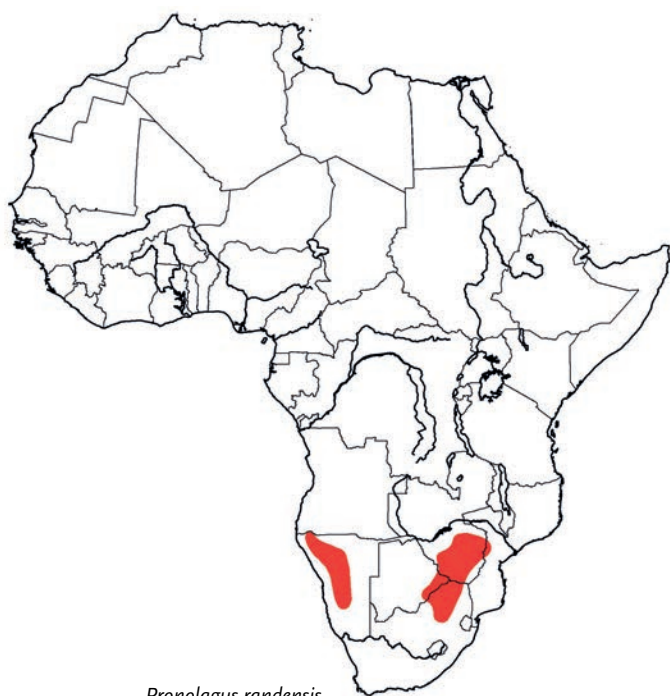

P. crassicaudatus. Ear shorter (60–80 mm); tail on average shorter (mean 65 mm); eastern South Africa; allopatric.

P. rupestris. HB: on average shorter (mean 447 mm), but with ear on average longer (mean 94 mm) and tail on average shorter (mean 86 mm); South Africa, and Malawi northwards to Kenya; allopatric.

P. saundersiae. Ear on average longer (mean 94 mm); tail on average shorter (mean 86 mm); marginally sympatric in part of range.

Distribution Endemic to Africa. South-West Arid (Namib) and Zambezi Woodland BZs. Two disjunct populations: (1) NE South Africa, E Botswana and Zimbabwe; (2) C and NW Namibia, and perhaps extreme SW Angola. Distribution is patchy because of specialized habitat requirements (see below).

Habitat Rocky kopjes, gorges and cliffs, and rocky hills with boulders. Rock crevices and boulders are an essential component of the habitat. In Botswana, occurs on isolated kopjes up to 22 km from

Pronolagus randensis

nearest kopjes (and from other populations) so, when necessary, individuals have to disperse across intervening non-rocky habitat. Where sympatric with *P. saundersiae* in hilly mountainous areas, *P. randensis* tends to be found on the drier low-lying mountain slopes where there are many jumbled boulders and rock crevices, whereas *P. saundersiae* is found at higher altitudes with fewer boulders and crevices, and higher rainfall.

Abundance Very common in the granite hills of Matopos Hills in Zimbabwe and sandstone formations of E Botswana (Smithers 1983).

Adaptations Mainly nocturnal but may feed and sunbathe in the late afternoon. During the day, rests in rock crevices, under boulders, or in thick grass close to rocks. If disturbed, stays under cover until the last moment and then disappears behind nearby rocks. Like all rock-hares, can leap from rock to rock, and run up steep rock faces to reach crevices. Characteristic flattened pellet-like droppings are deposited in middens (as in other *Pronolagus* spp.). Unlike hyraxes, which also live in rocky habitats, Jameson's Red Rock-hares do not expose themselves on observation boulders (Smithers 1983).

Foraging and Food Herbivorous. Grazes on grasses amongst rocks or at base of rocky hills. Congregates on recently burnt areas to feed on newly sprouting grass. No detailed information on diet.

Social and Reproductive Behaviour Generally solitary; sometimes seen in small groups of ♀ and young, or adult ♀ with one or two ♂♂. Several individuals may congregate when grazing (Smithers 1983). In Matopos Hills, Zimbabwe, most nocturnal observations were of single animals, and only 15% were of pairs (Peddie 1975, in Duthie & Robinson 1990).

Reproduction and Population Structure Probably breeds throughout the year in Zimbabwe (Peddie 1975, in Duthie & Robinson 1990). Pregnancies recorded in Jan, Jul and Aug; and lactating ♀♀ in Jun, Jul and Aug in Zimbabwe (no data for Feb, Mar, Apr, May, Nov, Dec; Smithers & Wilson 1979, as *P. crassicaudatus*). Litter-size: 1.1 (1–2), n = 8 (Smithers 1983). No information on rate of growth or age at maturation.

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Measurements

Pronolagus rupestris SMITH'S RED ROCK-HARE

Fr. Lièvre Roux de Smith; Ger. Smiths Rotkaninchen

Pronolagus rupestris (A. Smith, 1834). S. Afr. Quart. J. 2: 174. 'Rocky situations, South Africa' (probably Rhynsdorp District, South Africa).

Taxonomy Originally described in the genus *Lepus*. Formerly included in *P. crassicaudatus*. The taxonomic status of the East African *P. rupestris* is uncertain and requires investigation, and is here treated as conspecific with the southern African *P. rupestris*. Synonyms: *curryi*, *fitzsimonsi*, *melanurus*, *mülleri*, *nyikae*, *vallicola*. Subspecies: none. Chromosome number: 2n = 42 (as in all *Pronolagus* spp.).

Description Medium-sized. Pelage thick and dense, woolly and frequently characterized by a reddish undertone. Dorsal pelage grizzled (agouti) brown anteriorly; hairs pale cinnamon at base, with subterminal white band and black tip; dorsal pelage rufous posteriorly and bright rufous on rump; hairs rufous with white tip. Flanks paler; hairs mostly with white tip and fewer with black tip. Ventral pelage pale rufous to whitish-rufous. Head greyish-

brown. Cheeks greyish-white. Ears ca. 116% of GLS; similar in colour to head with many small off-white or brown hairs. Gular patch brownish. Nuchal patch rufous. Forelimbs bright rufous, contrasting with body colour. Hindlimbs pale rufous (not as bright as forelimbs); hairs whitish-rufous at tip. Soles of all feet very densely covered with dark grey hair. Tail medium-sized, usually black, or black and dark red. MS/HP ratio low (ca. 77%). Each principal incisor tooth with groove (close to inner margin of tooth) not filled with cement. Length of frontal bone almost equal to length of muzzle (cf. *P. saundersiae*).

Geographic Variation Pelage colour varies geographically (Smithers 1983).

Similar Species

P. randensis. Ear on average shorter (mean 84 mm); tail on average longer (mean 97 mm); allopatric.

P. saundersiae. Length of frontal bone shorter than length of muzzle; marginally sympatric in part of range.

Distribution Endemic to Africa. South-West Arid and Zambeian Woodland BZs; also some areas of Afroalpine–Afroalpine BZ. Two disjunct ranges: (1) NW South Africa; (2) SW Kenya, C Tanzania, Malawi and E Zambia. The two ranges are separated by ca. 1200 km. Not recorded from Botswana (Smithers 1971), Zimbabwe (Smithers & Wilson 1979), Swaziland (Monadjem 1998a) and Mozambique (Smithers & Lobão Tello 1976).

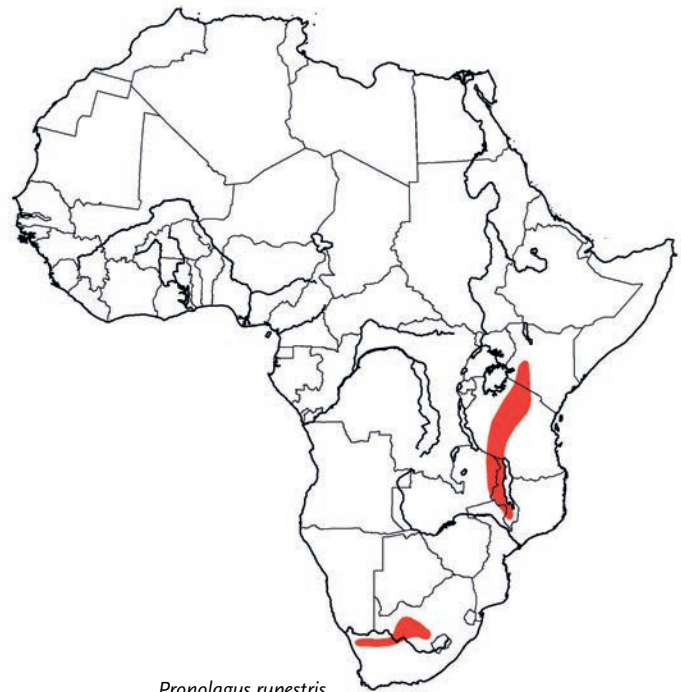

Habitat Rocky kopjes and rocky hillsides with boulders. Rock crevices and boulders are essential components of the habitat. Habitat very similar to other species of *Pronolagus*. In South Africa, generally found at lower elevations than *P. saundersiae* (Matthee & Robinson 1996).

Abundance In South Africa, fairly abundant throughout range; expected total population size exceeds 10,000 mature individuals (T. J. Robinson, unpubl.). No information on abundance for East African populations.

Adaptations Nocturnal. Emits a wide range of vocalizations: an alarm ‘tu ... tu’ when approached at night, and a grunt when disturbed before sunrise. Young individuals produce a scream when handled, and a ‘churring sound’ when disturbed under a rock (Duthie 1997). Large disc-shaped faecal pellets are deposited in middens (Duthie 1997). Adaptations likely to be similar to those of other rock-hares.

Foraging and Food Herbivorous. Forages near rocks, grazing mainly on grasses. In the Ngong Hills, Kenya, plant items in faecal pellets were grass epidermis (mainly *Ischaemum afum* 33.5%) and stem fibres (30.6%); small amounts of other grass were present, and a very small amount of dicotyledon epidermis (Stewart 1971b).

Social and Reproductive Behaviour Female prepares nest of fur from her body, suggesting that young remain for some time in a nest (Smithers 1983).

Pronolagus rupestris

Reproduction and Population Structure Females give birth to young from spring to summer (Sep–Feb) in South Africa. Gestation: 35–45 days. Litter-size: one or two (Duthie 1997). At birth young are likely to be altricial, with sparse covering of hair and eyes closed (Smithers 1983).

Predators, Parasites and Diseases No information.

Conservation IUCN Category: Least Concern.

Pronolagus saundersiae HEWITT'S RED ROCK-HARE

Fr. Lièvre Roux de Hewitt; Ger. Hewitts Rotkaninchen

Pronolagus saundersiae Hewitt, 1927. S. Afr. Quart. J. 2: 174. 'Rocky situations, South Africa' (probably Albany district, South Africa).

Taxonomy Originally described as *Pronolagus crassicaudatus saundersiae*. Referred to as a subspecies of *P. rupestris* by Meester *et al.* (1986) and Hoffmann & Smith (2005) but here, following Whiteford (1995) and Matthee & Robinson (1996), it is considered to be a valid species. Synonyms: *australis*, *barretti*. Subspecies: none. Chromosome number: $2n = 42$ (as in all *Pronolagus* spp.).

Description Medium-sized. Pelage thick and dense, woolly. Dorsal pelage grizzled (agouti) brown anteriorly; hairs pale cinnamon at base, with subterminal white band and black tip; dorsal pelage rufous posteriorly and bright rufous on rump; hairs rufous with white tip. Flanks paler; hairs mostly with white tip and some with black tip. Ventral pelage pale rufous to whitish-rufous. Head greyish-brown. Cheeks greyish-white. Ears ca. 116% of GLS; similar in colour to head with many small off-white or brown hairs. Gular patch brownish. Nuchal patch rufous. Forelimbs bright rufous, contrasting with body colour. Hindlimbs pale rufous (not as bright as forelimbs); hairs whitish-rufous at tip. Soles of all feet very densely covered with dark grey hair. Tail usually red or pale sandy colour. MS/HP ratio low (ca. 77%). Each principal incisor tooth with groove (close to inner margin of tooth) not filled with cement. Length of frontal bone shorter than length of muzzle (cf. *P. rupestris*).

Geographic Variation Pelage colour varies geographically (Smithers 1983).

Pronolagus saundersiae

Similar Species

P. crassicaudatus. HB on average longer; ear shorter (60–80 mm); tail on average shorter (mean 65 mm); sympatric in part of range.
P. randensis. Ear on average shorter (mean 84 mm); tail on average longer (mean 97 mm); marginally sympatric in part of range.
P. rupestris. Length of frontal bone almost equal to length of muzzle; marginally sympatric in part of range.

Distribution Endemic to Africa. South-West Arid (Karoo), South-West Cape and Highveld BZs. Recorded from Western Cape, Eastern Cape, KwaZulu–Natal and Mpumalanga Provinces, South Africa, along the Great Escarpment of South Africa.

Habitat Rocky kopjes and rocky hillsides with boulders. Rock crevices and boulders are an essential component of the habitat. Habitat very similar to that of other species of *Pronolagus*. Generally found at higher elevations than *P. rupestris* (Matthee & Robinson 1996).

Abundance Fairly abundant throughout the range and it is expected that their total population size exceeds 10,000 mature individuals (T. J. Robinson unpubl.).

Remarks Since this species was formerly included within *P. rupestris*, its biology is likely to be similar to that of *P. rupestris*. Comparative studies are required. No other information available.

Conservation IUCN Category: Least Concern.

Measurements

Pronolagus saundersiae

HB: 447 (380–535) mm, $n = 15$

T: 86 (50–115) mm, $n = 15$

HF: 92 (85–100) mm, $n = 15$

E: 94 (80–105) mm, $n = 15$

WT: 1.62 (1.35–2.05) kg, $n = 18$

GLS: 81.3 (70.6–91.9) mm, $n = 109$

GWS: 36.72 (32.7–41.4) mm, $n = 89$

P^2-M^3 : n. d.

Mesopterygoid space (width): 5.4 (4.1–8.5) mm, $n = 105$

Hard palate (minimum length): 6.9 (5.0–8.8) mm, $n = 106$

Upper principal incisor width: 2.5 (2.0–3.3) mm, $n = 99$

Bulla width: 6.6 (5.6–7.8) mm, $n = 3$

South Africa

Body measurements: Robinson & Dippenaar 1983a (not differentiated from *P. rupestris*)

Weight: Smithers 1983

Skull measurements: Whiteford 1995

Key References Duthie 1997; Smithers 1983.

Appendix: New Taxa 2005–2010

Gliridae

Graphiurus walterveyeni Holden and Levine, 2009. Bull. Amer. Mus. Nat. Hist. 331: 341. Distribution: riparian equatorial tropical rainforest, central Congo Basin, Democratic Republic of the Congo. Known altitude 398–431 m.

Muridae

Dendromus ruppi Dieterlen, 2009. Bonn. zool. Beitr. 56: 190. Distribution: Gilo, Imatong Mts, East Equatoria, South Sudan; altitude ca. 1800–1900 m.

Grammomys brevirostris Kryštufek, 2008. Acta Zool. Lituanica 18: 222. Distribution: Lemesikio, Loliondo, Loita Plains, Kenya (01° 30' S, 35° 09' E).

Hylomyscus anelli Carleton and Stanley, 2005. Proc. Biol. Soc. Washington 118: 636. Distribution: highlands in northern Zambia and westernmost Tanzania (Ufipa Plateau); known altitude 1220–2300 m. Remarks: Described as a subspecies of *Praomys denniae*; elevated to species by Carleton & Stanley (2005).

Hylomyscus arcimontensis Carleton and Stanley, 2005. Proc. Biol. Soc. Washington 118: 629. Distribution: Forested highlands from the Misuku Mts, northern Malawi; to Mt Rungwe and contiguous highlands, south-western Tanzania; eastwards through the Eastern Arc Mountain chain to the South Pare Mts, north-eastern Tanzania; known altitude 900–2410 m.

Hylomyscus endorobae (Heller, 1910: 3). Distribution: Highlands of west-central Kenya, including Mt Kenya, the Aberdare Mts and Mau Escarpment; ... known altitude 2135–3260 m. Remarks: Long considered a synonym of *H. denniae*; elevated to species by Carleton *et al.* 2006.

Hylomyscus pamfi Nicolas, Olayemi, Wendelen & Colyn, 2010. Zootaxa 2579: 38. Distribution: type locality Lalama forest, Benin (06° 57' N, 02° 09' E); also recorded from Lougha and Gotcha (Benin), Palimé (Togo), and Asijire and Osogbo (Nigeria).

Hylomyscus vulcanorum (Lonnberg and Gyldenstolpe, 1925: 4). Distribution: Mountains bordering the central Albertine Rift Valley, from south-western Uganda and east-central Democratic Republic of Congo, through Rwanda, to southern Burundi; known altitude 1670–3100 m. Remarks: Described as, and conventionally recognized as, a subspecies of *H. denniae*; elevated to species by Carleton *et al.* 2006.

Hylomyscus walterveyeni Nicolas, Wendelen, Barriere, Dudu and Colyn, 2008. J. Mammal. 89: 225. Distribution: Doudou Mounts, Ogooue-Maritime Province, SW Gabon (02° 09' S, 10° 30' E); 110 m.

Lophuromys chercherensis Lavrenchenko, W. Verheyen, E. Verheyen, Hulselmans and Leirs, 2007. Bull. Inst. R. Sci. Nat. Belg. Biol. 77:

102. Distribution: 22 km north-east Hirna (near road Hirna–Deder), Chercher Mts, eastern Ethiopia (09° 19' N, 41° 15' E, 2700 m).

Lophuromys kilonzoii W. Verheyen, Hulselmans, Dierckx, Mulungu, Leirs, Corti and E. Verheyen, 2007. Bull. Inst. R. Sci. Nat. Belg. Biol. 77: 33. Distribution: Magamba (04° 45' S, 38° 17' E; altitude 1550 m) (Tanzania).

Lophuromys machangui W. Verheyen, Hulselmans, Dierckx, Mulungu, Leirs, Corti and E. Verheyen, 2007. Bull. Inst. R. Sci. Nat. Belg. Biol. 77: 34. Distribution: Mt Rungwe (09° 10' S, 33° 39' E; altitude 2300 m), forest (Tanzania).

Lophuromys makundii W. Verheyen, Hulselmans, Dierckx, Mulungu, Leirs, Corti and E. Verheyen, 2007. Bull. Inst. R. Sci. Nat. Belg. Biol. 77: 38. Distribution: 'Gerodom' (foot of Mt Hanang along a brook (04° 28' S, 35° 23' E; altitude ca 2000 m) (Tanzania).

Lophuromys menageshae Lavrenchenko, W. Verheyen, E. Verheyen, Hulselmans and Leirs, 2007. Bull. Inst. R. Sci. Nat. Belg. Biol. 77: 99. Distribution: Suba Forest Station, Menagesha Forest, Central Ethiopia (08° 57' N, 38° 33' E, 2600 m).

Lophuromys pseudosikapusi Lavrenchenko, W. Verheyen, E. Verheyen, Hulselmans and Leirs, 2007. Bull. Inst. R. Sci. Nat. Belg. Biol. 77: 106. Distribution: Sheko Forest, south-west Ethiopia (07° 04' N, 35° 30' E, 1930 m). Remarks: The exact place of capture was in disturbed humid afro-montane forest situated ca. 800 m northwards from the local agricultural office of the Sheko settlement.

Lophuromys sabunii W. Verheyen, Hulselmans, Dierckx, Mulungu, Leirs, Corti and E. Verheyen, 2007. Bull. Inst. R. Sci. Nat. Belg. Biol. 77: 36. Distribution: Mbizi on the Ufipa Plateau, Tanzania (07.42° S, 31.40° E; altitude ±1750 m). Remarks: found on forest rim.

Lophuromys stanleyi W. Verheyen, Hulselmans, Dierckx, Mulungu, Leirs, Corti and E. Verheyen, 2007. Bull. Inst. R. Sci. Nat. Belg. Biol. 77: 31. Distribution: Mt Rwenzori-Bujuku, Uganda (00.22° N, 29.58° E; altitude 3700 m).

Praomys coetzeei Van der Straeten, 2008. Stuttgart. Beitr. Naturk. A, Neu. Ser. 1: 124. Distribution: Duque de Bragança (25 km N – 15 km E), Angola.

Otomys dollmani Heller, 1912: 5. Distribution: Known only from Mt Gargues, Mathews Range, central Kenya. Remarks: Long considered a subspecies of *O. irroratus* or *O. tropicalis*; specific validity clarified by Carleton & Byrne (2006).

Otomys orestes Thomas, 1900: 175. Distribution: Discontinuous in alpine habitats, ca. 2700–4200 m, from western and central Kenya. Remarks: Various considered as a synonym of *O. irroratus*, *O. tropicalis*, or *O. typus*; specific validity clarified by Carleton & Byrne (2006).

Otomys uzungwensis Lawrence and Loveridge, 1953: 61. Distribution: Mountain ranges in west central Tanzania to the Nyika Plateau, northern Malawi; altitude 1800–2750 m. Remarks: Conventionally considered a synonym of *O. typus*; specific validity clarified by Carleton & Byrne (2006).

Glossary

abbrev. = abbreviation

adj. = adjective

cf. = *confer*, compare with; as opposed to

Lat. = Latin

pl. = plural

q.v. = *quod vide*, 'which see'

acrocentric: describes a chromosome that has the centromere very near one end and therefore appears to have only one arm (= telocentric [*q.v.*] for practical purposes).

ad libitum: (*Lat.*) as much as one likes; having unrestricted access to a resource (e.g. water or food).

aestivate: state of torpor (*q.v.*) induced by cold or drought; usually associated with a reduced metabolic rate and inactivity.

aFN: (*abbrev.*) the total number of chromosomal arms in the autosomal chromosome complement of a species (*cf.* fundamental number [FN], which includes the chromosomal arms of the sex chromosomes as well as those of the autosomal [*q.v.*] chromosomes). Each metacentric (*q.v.*), submetacentric (*q.v.*) or subtelocentric (*q.v.*) chromosome is given a value of 2; each acrocentric chromosome is given a value of 1. *See also* fundamental number.

afroalpine: describes habitats and/or vegetation occurring above the treeline on African mountains. Includes montane grassland and heathlands.

afromontane: refers to mountainous regions in Africa, e.g. afromontane forests and afromontane grasslands.

agouti: the alternation of pale and dark bands of colour on a hair resulting in the pelage having a grizzled, speckled or 'pepper and salt' appearance.

Albertine Rift Valley: *see* Rift Valley (*q.v.*).

alisphenoid: bone in the skull.

allele: an alternative form of a gene. A diploid organism carries two alleles (which may be same or different) for each gene locus. At any one locus, there may be several possible alleles (although only two are present in a single organism).

allopatry (*adj.* **allopatric**): the situation where populations of the same or different species have non-overlapping geographic ranges; refers also to populations of the same, or different, species that are geographically separated. *cf.* sympatry (*q.v.*); syntopy (*q.v.*).

altimontane: collective term for the belts of ericaceous and afroalpine vegetation on the high mountains of tropical East Africa (White 1983).

altricial: describes young born in an undeveloped state. *cf.* precocial.

alveolus (*pl.* **alveoli**, *adj.* **alveolar**): small cavity; socket that houses the root of a tooth.

angular process: process at the posterior lower corner of the mandible; situated ventrally to the coronoid process (*q.v.*).

anteorbital: in front of the orbit (*q.v.*).

anterior palatal foramen (*pl.* **foramina**): foramen (*q.v.*) in the premaxilla and/or maxilla bone on the ventral surface of the skull

situated in rodents between the incisor teeth and the cheekteeth; foramina always in pairs and elongated in an anterior–posterior direction; sometimes referred to as the anterior incisive foramen. *See also* posterior palatal foramen.

anteroloph: a low transverse enamel ridge that forms part of the anterior cingulum located on the anterior rim of the upper molars of many rodents.

anterolophid: a low transverse enamel ridge that forms part of the anterior cingulum located on the anterior rim of the lower molars of many rodents.

anthropophilic: living or thriving with humans; inhabiting domiciles in man-made structures and buildings; thriving in habitats substantially modified by humans (e.g. towns, farmlands). *cf.* lithophilic (*q.v.*), phytophily (*q.v.*).

apomorphy (*adj.* **apomorphic**): a character state that distinguishes a group of biological organisms from others descended from a common ancestor. *cf.* plesiomorphy (*q.v.*).

arboreal: living above the ground (in trees and shrubs). *cf.* scansorial (*q.v.*); terrestrial (*q.v.*).

auditory bulla (*pl.* **bullae**): bony structure encapsulating the middle and inner ear, situated on the ventral surface of the skull. Often greatly inflated in some taxa of arid zone rodents (e.g. Gerbillinae, Dipodidae). Composed of several separate bones, which vary in size and inflation in different genera. Sometimes referred to as tympanic bulla. *See also* ectotympanic bulla.

auditory meatus (*pl.* **auditory meati**): the external opening of the ear; the passage leading from the tympanic membrane (ear drum) to the external ear.

autapomorphy: derived trait uniquely characteristic of a taxon.

autosomal: pertaining to any chromosome other than the sex chromosomes.

baculum (*pl.* **bacula**, *adj.* **bacular**): the os penis, or penis bone, which supports the penis in some mammals.

basal metabolic rate: metabolic rate required for survival in the thermal neutral zone (*q.v.*); a state that requires the lowest expenditure of energy when at rest.

basicranial axis: a line drawn in the lateral view of the skull indicating the position of the floor of the braincase, in the median line (Harrison & Bates 1991).

basisphenoid: cranial bone in middle of base of skull; the median posterior part of the sphenoid bone, forming part of the floor of the braincase.

bicuspid: having two points or cusps (particularly of teeth).

bifid: divided by a shallow or deep notch.

bipedal: body supported by the two hindlimbs; movement not using the forelimbs.

biserial: arranged in pairs (as in the cusps of molar teeth in some mammals, e.g. some rodents).

blastula: a hollow ball of undifferentiated cells (derived from a fertilized ovum by cell division), which represents one of the earliest stages of embryonic development.

- brachydont**: describes a premolar or molar tooth with low crowns.
cf. hypsodont (*q.v.*).
- braincase (= cranium)**: that part of the skull housing the brain; the part of the skull posterior to the front line of the orbits. *cf.* rostrum (*q.v.*).
- bushmeat**: meat for human consumption derived from non-domesticated mammals, birds and reptiles taken from their natural habitats and domiciles.
- bushveld**: savanna vegetation type characterized by a grassy ground layer and a moderately dense upper layer of shrubs and scattered trees.
- BZ**: (*abbrev.*) Biotic Zone.
- C or c**: (*abbrev.*) canine tooth; upper case denotes adult dentition, lower case denotes deciduous dentition (milk teeth). *See also* canine.
- c.u.**: (*abbrev.*) (*Lat. cum unguis* = with nail) sometimes added as a suffix to the hindfoot measurement (HF) to emphasize that the measurement includes the claw. *cf.* s.u. (*q.v.*).
- canine**: the tooth situated immediately posterior to the incisors or, if incisors are absent, the most anterior tooth. Tall and pointed in most mammals, but absent in rodents and lagomorphs, and in some other orders. By definition, situated on the maxilla bone. *See also* diastema (*q.v.*), dental formula (*q.v.*).
- cauda epididymides**: the ducts of the epididymides at the posterior end of the testes, which carry sperm from the testes to the vas deferens, which, in turn, carries sperm to the penis. Sometimes used to store sperm prior to copulation.
- CbL**: (*abbrev.*) *see* condylobasal length.
- cement**: bone-like material that covers part of tooth; material that anchors tooth into its socket. In lagomorphs, may be present in groove on front surface of incisor tooth.
- central Africa**: Cameroon (south of the Sanaga R.), Central African Republic (but only south of ca. 7° N), Equatorial Guinea, Gabon, DR Congo (except SE). Mainly rainforest habitats and rainforest–savanna mosaics.
- cf.** (in general usage): compare or compare with. In the context of descriptions, implies a difference or contrast: e.g. Upper incisors do not have a longitudinal groove (*cf.* *Meriones*).
- cf.** (in taxonomy): precedes the specific name if there is uncertainty in the assignment.
- cheekteeth**: the premolar (*q.v.*) and molar (*q.v.*) teeth combined; the chewing surface for rodents and lagomorphs.
- choana (pl. choanae)**: the openings of the internal nostrils on the skull, situated immediately posterior to the bony palate.
- chromosome**: one of the thread-like bodies within the nucleus of a cell that carry the genes (genetic material) in linear order; each chromosome is composed of one long molecule of DNA (and two long molecules at cell division). Chromosomes occur in pairs (one from each parent) and are visible as rod-like bodies in cells that are dividing. The total number of chromosomes in a cell is expressed as the diploid number (2n).
- cingulum (pl. cingula)**: ridge around the base of the crown of a tooth.
- clade**: branch of a phylogenetic tree containing the set of all organisms descended from a common ancestor.
- cladistic (analysis)**: a methodology that provides a classification in which organisms are grouped in terms of the time when they had a common ancestor.
- cline (adj. clinal)**: in context of geographic variation, a gradual and sequential change of a character(s) without a significant break such as would justify division into separate subspecies or species.
- CNL**: (*abbrev.*) condylo-nasal length; measurement from the most anterior part of the nasal bone to the most posterior part of the occipital condyle (exoccipital) on the same side of the skull; a similar measurement to ‘greatest length of skull’.
- comparatively**: used in the context of describing the size of one character compared with the size of the same character in a different species. Sizes described as small, medium or large (if range is divided into three) or very small, small, medium, large, very large (if range is divided into five). *cf.* relatively (*q.v.*).
- competitive exclusion**: the principle that two different species cannot indefinitely occupy the same ecological niche.
- concave**: having a curvature that curves inwards; having an outline or a surface curved like the interior of a circle or sphere. *cf.* convex (*q.v.*).
- concavity**: a concave depression in an outline or surface.
- conceptus**: embryo prior to implantation.
- conductance**: in thermal biology, the rate at which heat passes across a temperature gradient, e.g. the density and thickness of the pelage affects the rate at which body heat passes from the body to the outside. Thick pelage, which traps and holds air, results in low thermal conductance.
- condylar process**: process at the posterior upper corner of the mandible, which forms the lower hinge of the jaw articulation; fits into the glenoid fossa of the skull.
- condyle**: a rounded process on a bone, which articulates with a socket-like concavity in another bone.
- condylobasal length (CbL)**: the length of the skull from the most posterior point of one occipital condyle to the most anterior point of the premaxilla on the same side.
- congeneric**: belonging to the same genus.
- conspecific**: belonging the same species.
- convex**: having a curvature that bulges outwards; having an outline or a surface curved like the exterior of a circle or sphere. *cf.* concave (*q.v.*).
- coprophagy (adj. coprophagous)**: condition in which an individual reingests its own faeces; any animal that feeds on faeces.
- copulatory plug**: plug formed in the vagina of the female after copulation; formed from seminal fluids of the male. Prevents or reduces the chance of sperm from another male(s) entering the female reproductive tract if the female copulates again soon after copulation with the first male.
- coronoid process**: angular pointed process on the upper margin of the mandible, situated anteriorly to the condylar process (*q.v.*); does not participate in the jaw articulation.
- corpus luteum (pl. corpora lutea)**: a glandular mass of tissue on the surface of an ovary, that develops after the extrusion of an ovum from a Graafian follicle (*q.v.*); secretes the hormone progesterone.
- cotype**: originally synonymous with syntype but now used as synonym of paratype (*q.v.*).
- CR**: (*abbrev.*) *see* crown–rump length.
- cranial profile**: the shape of the cranium (that part of the skull that surrounds the brain) when viewed from the side.
- craniodental**: pertaining to the skull and teeth.

- cranium:** that part of the skull housing the brain. Also called braincase.
- crepuscular:** pertaining to the twilight, or active during twilight, when light intensity is higher than at night but lower than during the day. *cf.* diurnal (*q.v.*); nocturnal (*q.v.*).
- crown:** (1) top of head; (2) exposed part of a tooth (visible above gum), especially the grinding surface.
- crown–rump length (CR):** distance from the crown of head to the rump of a foetus (i.e. maximum length of a foetus in its natural form).
- cursorial:** pertaining to running.
- cusp** (*adj.* **cuspidate**): a prominence or sharp point, such as on the occlusal surface of some teeth. *See also* t.
- Cyrenaica:** a region of north-east Libya. Includes the Cyrenaican Plateau and that part of the Mediterranean Coastal Biotic Zone between the plateau and the sea, as well as drier terrain south of the plateau.
- cytochrome b:** a protein involved in electron exchange in the mitochondria. It is the product of a gene in the mitochondrial genome. The sequence of this gene is often compared between species in phylogenetic studies to infer relatedness.
- Dahomey Gap:** the geographic region where savanna habitat extends southwards to the West African coast in E Ghana, Togo, Benin (formerly Dahomey) and extreme SW Nigeria. The presence of savanna forms a break (or gap) in the extensive Rainforest Biotic Zone, which extends along the West African coast from Sierra Leone to Cameroon. The Dahomey Gap is an important biogeographical barrier separating the faunas to the east and west of the Gap.
- Dega:** Ethiopian word for the temperate agricultural/economic altitudinal zone, about 2300–3000 m, warm enough for cereal-based agriculture.
- delayed implantation:** a means of lengthening the interval between copulation and parturition by delaying the implantation of the blastula (*q.v.*), so that both copulation and parturition can occur in the most optimal seasons. Development to blastula stage is followed by a period of halted development lasting several weeks or months; then the blastula implants and embryonic development proceeds normally, usually without any further interruption, until the young is born.
- deme:** a unit of population that is interbreeding and separate from any other such population.
- dental formula:** a simple numerical method of denoting the number of incisor (I), canine (C), premolar (P) and molar (M) teeth on one side of the upper jaw and lower jaw, and the total number of teeth. For example, the dental formula of a primitive mammal is $I^{3/3}, C^{1/1}, P^{4/4}, M^{3/3} = 44$, which means there are three incisors, one canine, four premolars and three molars on each side of the upper jaw and also the lower jaw, making a total of 44 teeth. The formula may also be expressed in the form $^{3143}/_{3143} = 44$. Each incisor, premolar and molar is numbered according to its position in the tooththrow; superscript numbers indicate upper jaw, subscript numbers indicate lower jaw (mandible), e.g. P^4 (upper fourth premolar), M_2 (lower second molar). Dental formula, with respect to the presence and number of each of the four types of teeth, varies greatly between orders, families and genera of mammals. *See also* incisor (*q.v.*), canine (*q.v.*), premolar (*q.v.*) and molar (*q.v.*).
- diastema:** space in the mouth between the incisor teeth and cheekteeth in those mammals that feed on grasses, herbs etc. (e.g. rodents, hares, rabbits, ruminants, etc.).
- dichromatism:** condition in which members of a species show one of only two distinct colours or colour-patterns.
- diphyly:** the derivation of a taxon from two separate lines of descent. *cf.* monophyly (*q.v.*).
- diploid number (2n):** total number of chromosomes (including sex chromosomes) in a somatic cell of an organism.
- distal:** the end of any structure furthest away from the mid-line of the body or furthest from the point of its attachment. *cf.* proximal (*q.v.*).
- distichous:** arranged in two rows; e.g. long hairs of the tail in some anomalurids and some dormice (as opposed to the hairs being evenly spread all around the tail).
- diurnal:** pertaining to the daytime, or active during daytime, when light intensity is high. *cf.* crepuscular (*q.v.*); nocturnal (*q.v.*).
- DNA:** (*abbrev.*) deoxyribonucleic acid; the very large self-replicating molecule that carries the genetic information of a chromosome; each molecule is composed of two complementary chains of DNA.
- DNA hybridization:** technique of comparing the similarity between two DNA molecules by reassociating single strands from each molecule and determining the extent of double-helix formation. In phylogenetics, this technique is used to determine the relatedness of two or more taxa.
- dorsoventral** (*adj.* **dorsoventrally**): from dorsal to ventral surface; from back to belly of an animal.
- E:** length of external (outer) ear (= pinna), measured from tip of ear to the posterior point of the ear conch. For all mammals, length (and shape) is often affected by preservation.
- East Africa:** Kenya, Uganda, Rwanda, Burundi and Tanzania.
- eastern Africa:** SE Sudan, Ethiopia, Eritrea, Djibouti, Somalia, Kenya, Uganda, Rwanda, Burundi, Tanzania, Malawi (but only south of L. Malawi and east of the Shire R. Valley) and Mozambique (but only east of Malawi and north of the Zambezi R.).
- ectotympanic bone:** sheathing bone, typically hemiglobular in shape, that encloses the middle ear chamber and auditory ossicles in rodents and supports the tympanic membrane. *See also* auditory bulla.
- edaphic:** influenced by conditions of soil or substratum.
- emargination:** a distinct notch or indentation.
- embryo number:** number of foetuses within the uterus or uteri of the female (as assessed by autopsy). Expressed as mean number (with range from minimum to maximum, and sample size). *cf.* litter-size (*q.v.*).
- endemic:** restricted to, peculiar to, or prevailing in, a specified country or region.
- entoconid:** principal cusp located at the posterior lingual (inner) side of a lower molar.
- Eocene:** geological epoch (within the Tertiary period), 38–55 mya.
- epiphysis** (*pl.* **epiphyses**): any part of a long bone that is formed from a different centre of ossification and which later fuses with the bone to form its terminal part.
- evaporative water loss:** the loss of water from the body through the skin and/or the lungs. A mechanism used by mammals to reduce T_b (*q.v.*) when T_a (*q.v.*) is high. Excessive evaporative water loss may lead to dehydration if sufficient water is unavailable.

- exfoliating:** shedding flakes (e.g. of bark), or breaking into relatively thin slabs (e.g. of granitic rock).
- exoccipital condyles:** a pair of projections from the occipital bone on either side of the foramen magnum (*q.v.*), which articulate with the first vertebra.
- extant:** living at the present time. *cf.* extinct.
- extrabuccal:** condition in which incisor teeth extend anteriorly to the lips and are visible externally.
- F. R.:** (*abbrev.*) Forest Reserve.
- facultative:** having the capacity to switch from one mode of life or action to another depending on conditions or circumstances. *cf.* obligate (*q.v.*).
- fenestra** (*pl. fenestrae*): opening on a bone, or between two bones, e.g. on maxilla.
- flank:** the side of the body of a mammal.
- FN:** (*abbrev.*) *see* fundamental number.
- folivore** (*adj. folivorous*): an animal that eats leaves.
- foramen** (*pl. foramina*): an aperture (which is usually small, round or elliptical) in a bone, or between bones, for the passage of a nerve, blood vessel or muscle.
- foramen magnum:** the large opening at the posterior end of the skull through which the spinal cord passes.
- forest island:** *see* relict forest.
- form:** in taxonomy, a taxonomic unit (usually named) whose status as either a species or a subspecies is uncertain; one of the varieties found in a polymorphic species.
- fossorial:** adapted for digging; burrowing. *cf.* subterranean (*q.v.*).
- fovea:** small pit or depression.
- frontal bone:** one of a pair of bones forming the anterior part of the braincase.
- frugivorous:** fruit-eating.
- fundamental number (FN):** an ambiguous term sometimes defined as (1) the total number of chromosomal arms in the full chromosomal complement of an organism (i.e. including the sex chromosomes), or (2) the total number of chromosomal arms found in the autosomal chromosomes only (i.e. excluding the sex chromosomes). When only the autosomal chromosomes are included, some authors (but not all) use aFN instead of FN to avoid ambiguity. For further details, *see* aFN.
- fynbos:** the heath shrublands characteristic of the Cape Floristic Kingdom (within the South-West Cape Biotic Zone) of South Africa. Dominant plants are sclerophyllous, evergreen, low (<3 m), bushy and fine-leaved, but there are also scattered taller bushes and, less often, very widely spaced trees. Contains an exceptionally high number of endemic species of plants. The three main components on nutrient-poor sandy soils are species of Ericaceae, Restionaceae and Proteaceae. Also includes 'renosterveld' (dominated by species of Asteraceae) on nutrient-rich silt or clay soils.
- G. R.:** (*abbrev.*) Game Reserve.
- gallery forest:** type of forest outlier (in a savanna region) found in narrow sheltered valleys and ravines on hillsides, where soils are moist enough, and conditions humid enough, to support rainforest trees (Rosevear 1953).
- genotype:** genetic term to describe the genetic constitution of an individual inherited from its parents. *cf.* phenotype (*q.v.*).
- gestation:** the development of embryo/foetus that takes place in the uterus; the period during which this development takes place.
- The gestation period is defined as the interval between conception and parturition (birth). Strictly speaking, the gestation period is not the interval between copulation (mating) and parturition (birth), although many authors take it to be this interval.
- glans penis:** the bulbous tip of the penis.
- glenoid fossa (= glenoid):** the cavity (fossa) in the squamosal bone of the skull for the articulation of the condyle of the mandible (lower jaw) in mammals; visible on lateral and/or ventral views of skull depending on the taxon.
- GLS:** greatest length of skull, measured from anterior end of incisor teeth or nasal bone (whichever is most anterior) to the posterior end of the skull (occiput, occipital condyles or auditory bullae, whichever is most posterior).
- Graafian follicle:** the structure in the mammalian ovary that contains the developing ovum, and from which the ovum is released at the time of ovulation.
- gracile:** lightly built. *cf.* robust
- granivore** (*adj. granivorous*): an animal that eats grains and seeds.
- gregarious:** living together in groups, flocks, herds.
- Gregorian Rift Valley:** *see* Rift Valley.
- guard hair:** long thin bristle-like hairs, mainly on the back and flanks, which project beyond the soft hairs of the pelage; when present, conspicuous but never as numerous as soft hairs; probably tactile in function.
- gular:** pertaining to the upper part of the throat (the gula) as in gular gland, gular pouch, gular region. *See also* gular patch.
- gular patch:** in lagomorphs, patch of hair on throat, often contrasting in colour with that of the surrounding pelage; may be referred to as gular collar when extends dorsally on neck. *See also* nuchal patch.
- GWS:** (*abbrev.*) greatest width of skull; in rodents, usually across the widest point of the zygomatic arches, although in some species the widest point is across the braincase. *See also* zygomatic arch.
- hallux:** the first digit of the hindlimb; the big toe.
- hamada:** flat plain covered with pebbles of various sizes on a hard substrate in an arid environment. Much of the Sahara Desert is formed of hamada.
- hard palate:** the bony ventral part of the skull (*see also* palate). In lagomorphs, the hard palate is much reduced; the shortest longitudinal distance between posterior end of the palatal foramina and the anterior end of the mesopterygoid fossa (across the 'bony palate') is a diagnostic character. *See* Figure 114. *See also* mesopterygoid space.
- HB:** (*abbrev.*) length of head and body (measured from the tip of the nose to the most posterior point of the pelvis (anterior to the first tail vertebra).
- HF:** (*abbrev.*) length of hindfoot measured from the 'ankle bone' to the tip of the longest digit; usually measured without including the claw. *See also* c.u.; s.u.
- hibernaculum** (*pl. hibernacula*): a place, domicile or roost where an animal hibernates.
- hibernation:** a state of inactivity accompanied by a reduction in metabolic rate (below basal metabolic rate [*q.v.*]), lower T_b and slow breathing. Occurs when T_a is low and food is scarce; usually lasts for weeks or months; not common in African mammals (*cf.* torpor).

- high-crowned:** refers to structure of the teeth in the toothrow of herbivorous mammals in which the premolar and/or molar teeth are tall; such teeth have open roots, grow continuously, and the crown is worn down (due to the abrasive action of chewing grass) at the same rate as the tooth grows.
- high forest:** rainforest that has matured, stabilized and reached the climax stage of succession.
- highveld:** high plateau characteristic of inland southern Africa, dominated by grasses.
- Holocene:** epoch of the Quaternary period (*q.v.*) following the Pleistocene epoch (*q.v.*), present time to ca. 11,000 years ago. Sometimes referred to as the 'Recent' epoch.
- holotype (= type):** the single specimen designated or indicated by the original author of the original description of a new species or subspecies, to be the standard reference to the essential characters of the new taxon. *see also* cotype (*q.v.*), lectotype (*q.v.*), neoparatype (*q.v.*), neotype (*q.v.*), paratype (*q.v.*), syntype (*q.v.*), topotype (*q.v.*) and type locality (*q.v.*).
- home-range:** the area (expressed in square metres, or square kilometres) routinely used by an animal for its day-to-day activities and requirements, and which contains the resources required for survival and reproduction. Within the home-range there may be a 'core area' or 'centre of activity', which is utilized more frequently than other parts (e.g. 80% or 90% of known time-based observations). *cf.* territory (*q.v.*).
- homoplasy:** similarity between different organisms or taxa resulting from evolution along similar lines (e.g. convergent evolution) rather than descent from a common ancestor.
- hyperthermia:** elevation of body temperature above normal limits due to increase in T_a (*q.v.*) or increase in metabolic rate. *cf.* hypothermia (*q.v.*).
- hypocone:** in rodents, the cusp (t8) located centrally in the posterior lamina of an upper molar tooth.
- hypoconid:** principal cusp located at the posterior lingual side of a lower molar in rodents.
- hypothermia:** drop in body temperature below normal limits; occurs in some small mammals when T_a (*q.v.*) falls, and is a means of conserving energy in cold weather. *cf.* hyperthermia (*q.v.*).
- hypsodont:** describes a premolar or molar tooth with high crowns; has short roots.
- I or i:** (*abbrev.*) incisor (*q.v.*) tooth; upper case denotes adult dentition, lower case denotes deciduous dentition (milk teeth). *See also* incisor.
- I. (pl. Is.):** (*abbrev.*) Island.
- I¹–M³:** (*abbrev.*) the length of the toothrow from the anterior end of the first upper incisor to the posterior end of the last molar. In taxa where the last molar is M² (instead of M³), the measurement is I¹–M².
- implantation:** the embedding of a blastula (*q.v.*) in the lining of the uterus.
- incertae sedis:** (*Lat.*) refers to a taxon of uncertain status and which may be taxonomically invalid.
- incisive foramen (pl. foramina):** *see* anterior palatal foramen (*q.v.*).
- incisor:** tooth rooted in the premaxillary bone (most anterior bone of upper jaw) and in an equivalent position in the mandibular bone (lower jaw); always anterior to the canine teeth, if present.
- In rodents, there is always one incisor tooth in each side of upper and lower jaws. The number and form of incisor teeth varies in different species in other orders of mammals. *See also* dental formula.
- infraorbital foramen (pl. foramina):** foramen that connects the orbit (eye-socket) with the rostrum (premaxilla and maxilla bones); outer surface often expanded to form part of the zygomatic plate (*q.v.*); foramen contains the masseter medialis muscle.
- inner:** nearest to mid-line of body, e.g. inner incisor, inner margin of ear.
- insectivore (adj. insectivorous):** an animal that eats insects.
- inselberg:** isolated rocky hill; term used mainly in western Africa. *See also* jebel; kopje.
- interaual:** between the ears.
- interorbit (= interorbital constriction):** narrowest part of the skull between the orbits when viewed dorsally at the level of the frontal bones.
- interparietal:** bone (not paired) on dorsal surface of the skull, lying between and partly posterior to the parietal bones.
- inter-specific:** between different species.
- intra-specific:** within one species; between members of the same species.
- invagination:** the formation of a cavity by the in-sinking of the outside wall or surface of a tissue or structure, thereby drawing an exterior layer into the interior of the structure to form the lining of the cavity; a cavity formed by the process of invagination.
- Isoptera:** taxonomic order containing the termites (within the phylum Insecta).
- isozyme:** any one of several different forms of an enzyme encoded by the same or different genes that differ in properties such as optimum pH or isoelectric point.
- iteroparous:** repeated reproduction throughout a season or a lifetime (*cf.* semelparous – reproduces once and then dies).
- jebel:** isolated rocky hill in savanna and arid habitats; term used mainly in northern Africa. *See also* inselberg; kopje.
- jugal:** bone of the skull that forms the middle part of the zygomatic arch (*q.v.*); anteriorly joins the maxillary process (*q.v.*) of the maxilla bone and posteriorly joins the squamosal process of the squamosal bone.
- Kaokoveld:** area of sandstone and lava hills of the Namib Desert (Biotic Zone 11b) in NW Namibia, inland from the Skeleton Coast.
- Karoo:** southern African term for grassy dwarf shrubland on the semi-arid central plateau of the western half of South Africa at altitudes of 500–2000 m.
- karyogram:** a photographic representation of a karyotype (*q.v.*) as it appears at mitosis. Individual chromosomes are arranged in pairs from largest to smallest.
- karyological:** pertaining to the chromosomes.
- karyotype:** the chromosomes in the cell of an animal. *See also* karyogram.
- Kolla:** Ethiopian term for the tropical agricultural/economic altitudinal zone, about 800–1500 m, warm enough for coffee-growing.
- kopje:** rocky hill with boulders, rock crevices and sparse vegetation; term used mainly in southern Africa. *See also* inselberg (*q.v.*); jebel (*q.v.*).

- labial:** pertaining to the lips; situated near the lips; on the outer side of the teeth within the mouth. *cf.* lingual (*q.v.*).
- labially:** in the direction of the lips. *cf.* lingually (*q.v.*).
- lachrymal bone:** small bone in skull situated at the upper anterior margin of the orbit, near the lachrymal (tear) gland.
- lambdoid crest (= supraoccipital crest):** crest or ridge of bone running transversely across back of the skull at the junction of the dorsal (parietal) and posterior (occipital) bones of the braincase.
- lambdoid suture:** the line at the junction of the occipital and parietal bones of the skull. May be clearly defined in juveniles or obscured by complete fusion in adults, or by the formation of a lambdoid crest.
- lamina** (*pl.* **laminae**): in the context of premolar and molar teeth, a transverse row of cusps (e.g. t1, t2 and t3, or t4, t5 and t6, etc.), which, when worn, form a transverse ridge of bone and dentine across the tooth.
- lectotype:** a specimen chosen from syntypes (*q.v.*) to stand as 'the type' of a species or subspecies when no holotype (*q.v.*) was designated by the author who described the new species or subspecies.
- lenticular:** lens-shaped.
- limiting factor:** the principle that the growth or functioning of an organism is limited when any essential factor (or resource) is lacking or in short supply, regardless of the quantity available of any other factor (or resource). The principle may also be applied to the proliferation and/or distribution of a population or species.
- lingual:** pertaining to the tongue; situated near the tongue; on the inner (tongue) side of the mouth. *cf.* labial (*q.v.*).
- lingually:** in the direction of the tongue. *cf.* labially (*q.v.*).
- lithophilic:** loving, or thriving amongst, stones, rocks; inhabiting domiciles in caves, on cliffs, or under or amongst rocks etc. *cf.* anthropophilic (*q.v.*); phytophilyc (*q.v.*).
- litter-size:** number of young born to a female. Expressed as mean number (with range from minimum to maximum, and sample size). *cf.* embryo number (*q.v.*).
- lobule:** small lobe.
- localized movements:** movements of an animal within part or all of its home-range within a single day or within a limited period of time. *cf.* migration (*q.v.*); nomadic movements (*q.v.*).
- longitudinal:** lengthwise; running in a head to tail direction. *cf.* transverse (*q.v.*).
- loph:** enamel crest or ridge on the cheekteeth of rodents whose principal orientation is transverse to the longitudinal axis of the teeth.
- lophate:** condition in which the cross-connections of enamel elements, on the cheekteeth of rodents, are emphasized, forming a series of more-or-less well defined lophs (*q.v.*).
- lowveld:** savanna at lower altitudes below the Great Escarpment of South Africa, with vegetation consisting of a grassy lower layer and a woody upper layer of shrubs and/or trees, at either high density (woodland) or intermediate density (bushveld, *q.v.*).
- M:** (*abbrev.*) molar tooth. *See also* molars.
- M¹–M³:** (*abbrev.*) measurement of the length of the three upper cheekteeth (first molar to third molar) in small rodents (e.g. Muridae, Dipodidae, etc.).
- Maghreb:** *see* North-West Africa.
- malleus:** the most external bone of the three ossicles of the middle ear, the handle of which is joined to the ear drum.
- mandible:** lower jaw.
- mandibular ramus:** one of the two branches (sides) of the mandible (*q.v.*); the two rami are joined at the mandibular symphysis.
- masseteric tubercle:** knob-like bony projection on maxilla bone (for attachment of part of the masseter muscle) just anterior to first cheektooth, present in some rodents (e.g. squirrels).
- mastoid:** a bone on the posterior ventral part of the skull, immediately behind the auditory meatus (*q.v.*); usually small in size, but largely swollen, as is the auditory bullae, in some arid-adapted rodents (e.g. gerbils, jerboas).
- matorral:** Mediterranean bush-like vegetation.
- maxilla** (*pl.* **maxillae**): one of the pair of bones in the skull that forms that part of each upper jaw in which the canine (*q.v.*) if present and cheekteeth (premolars and molars) (*q.v.*) are rooted.
- maxillary:** pertaining to the maxilla (*q.v.*).
- maxillary process:** projection of bone from the maxilla, which forms the anterior portion of the zygomatic arch (*q.v.*); usually oriented vertically to the anterior–posterior line of the skull.
- meatus:** a passage or channel; the opening of a passage.
- medial:** situated in the middle.
- melanistic:** having an abnormally large amount of black or dark pigment in pelage and skin.
- mesa:** Ethiopian word for the micro-habitat (usually on slopes) within afroalpine moorlands and grasslands, where it is higher and drier than surroundings areas, so dominated by (usually) *Alchemilla*.
- mesoloph (-id):** low transverse enamel ridge found on the molar teeth of many rodents, situated between the paracone (*q.v.*) and metacone (*q.v.*) and extending laterally from the mid-line of the tooth.
- mesopterygoid fossa:** U- or V-shaped depression on the ventral aspect of the skull posterior to the palate and between the pterygoid processes (*q.v.*).
- mesopterygoid space:** the maximum lateral distance across the mesopterygoid fossa (*q.v.*); a diagnostic measurements in lagomorphs. *See also* bony palate.
- metabolic rate:** *see* basal metabolic rate (*q.v.*).
- metabolic water:** water produced by oxidative processes within the body; an important source of water for arid-adapted mammals when free (drinking) water and water within the food is in short supply or unavailable.
- metacarpals:** the long bones of the hand, situated between the carpal bones of the wrist and the proximal phalanges of the fingers.
- metacentric:** describes a chromosome with the centromere at or very near the middle of its length, so there are two arms of equal or almost equal length (ratio not greater than 1 : 1.1). *cf.* submetacentric (*q.v.*).
- metacone:** in rodents, the cusp (t9) located on the labial side of the posterior lamina of an upper molar tooth.
- metatarsals:** the long bones of the foot, situated between the tarsal bones of the ankle and the most proximal phalanges of the toes; very elongated in saltatorial species (e.g. jerboas).

- microcomplement fixation:** in molecular evolutionary studies, species can be compared by the extent to which antibodies to the proteins of one species cross-react to the proteins of another species. The extent of cross-reaction is indicative of the similarity of the proteins and, by inference, the evolutionary affinity of the two species. Albumin is a protein commonly used for these studies.
- migration:** movements of species that travel, predictably and more-or-less directly, from one habitat to another (and back again), along predetermined routes, in response to seasonal changes in climate, food supply or any other resource. *cf.* localized movements (*q.v.*); nomadic movements (*q.v.*).
- milk teeth:** teeth (usually simple) occurring in newborn mammals, or appearing soon after birth, and preceding the permanent teeth of the adult animal. Also called deciduous teeth.
- Miocene:** geological epoch (within the Tertiary period), ca. 5–23 mya.
- miombo:** a vernacular name applied to trees in the genus *Brachystegia*; a type of savanna woodland in the Zambezian region where *Brachystegia* spp. are the commonest trees or one of the commonest trees.
- Mistbelt:** foothills along the eastern Great Escarpment that experience regular fogs, with vegetation comprising mainly grasslands and patches of afro-montane forest in protected valleys and ravines.
- mitochondrial DNA:** the small amount of DNA contained within the mitochondria of a cell.
- molar:** grinding tooth or teeth on the maxilla bone; the most posterior teeth of the cheekteeth in adult mammals. Not preceded by deciduous (milk) teeth. Each molar tooth has many cusps arranged in a standardized way that is diagnostic for the taxon. The number of molars varies in different taxa, but is usually three in each ramus of the upper and lower jaw of rodents. The relative size of M1, M2 and M3 varies according to taxon; commonly M1 is the largest and M3 is the smallest. Because the molar teeth do not grow continuously, wear of the molars (resulting in differing patterns of dentine and enamel) provide a relative (but rarely absolute) measure of the age of an individual rodent. *See also* dental formula.
- molariform:** similar in form to a molar tooth; used to describe the form of the premolar teeth in some taxa.
- monoestrous:** having one litter per year. For species and/or populations described as being monoestrous, each female has one litter/year. *cf.* polyoestrous (*q.v.*).
- monogamy** (*adj.* **monogamous**): a mating system in which one male mates with one female, usually for the whole of an animal's life. Neither sex has the opportunity of monopolizing additional members of the opposite sex. Fitness often maximized through shared parental care. *cf.* polygyny (*q.v.*).
- monophyletic:** describes a taxonomic group descended from a common ancestor that was itself a member of that taxonomic group, and including *all* the descendants of that ancestor. *cf.* paraphyletic (*q.v.*); polyphyletic (*q.v.*).
- monophyly:** derivation of taxa from a common ancestor. *cf.* diphyly (*q.v.*), polyphyly (*q.v.*).
- monotocous:** normally having only one young per litter (twinning, if it occurs, is very rare and abnormal). *cf.* polytocous (*q.v.*).
- monotypy** (*adj.* **monotypic**): describes a taxon containing only one immediately subordinate taxonomic unit, e.g. a monotypic family contains only one genus; a monotypic genus contains only one species, a monotypic species contains no subspecies. *cf.* polytypy (*q.v.*).
- mopane:** a vernacular name applied to the tree *Colophospermum mopane*; a type of savanna woodland in the Zambezian region in which *C. mopane* is the commonest species of trees.
- MS/HP:** in Lagomorpha, the ratio of the mean width of the mesopterygoid space (MS) to the mean minimum length of the hard palate (HP), expressed as a percentage. *See* Figure 114.
- Mt:** (*abbrev.*) Mount.
- mtDNA:** (*abbrev.*) mitochondrial DNA (*q.v.*).
- Mts:** (*abbrev.*) Mountains.
- muzzle:** the snout; the nose and jaws of a mammal.
- mya:** (*abbrev.*) millions of years ago.
- n. d.:** (*abbrev.*) no data.
- N. P.:** (*abbrev.*) National Park.
- neonate:** a newly born animal.
- neoparatype:** any specimen described at the same time as the neotype (*q.v.*).
- neotype:** a specimen selected as the type in cases where the primary types are definitely known to be lost or destroyed.
- nipple:** external opening of a mammary gland. Nipple number and position vary according to the taxon, but are consistent within a species. Nipples arranged in pairs, one of the pair on each side of the body. Nipple number given as: number on one side of the body, and total for both sides. For example, in some murid rodents, nipples are found in the pectoral and inguinal regions, and the number is given as, e.g. 1 (pectoral) + 2 (inguinal) (all on one side) = 6 (both sides). In squirrels, nipples are more evenly spaced, and are given as axillary + pectoral + abdominal + inguinal (all on one side) = total (both sides).
- nipple-clinging:** the behaviour of neonates and unweaned young that remain semi-permanently attached to the nipples of the mother (including while she is foraging) for a period of several days to several weeks. In some species, there is a gap between the two deciduous upper incisor teeth, which assists in nipple-clinging.
- nipple-dragging:** situation when a mother drags her neonates and unweaned young, firmly attached to her nipples, when she is active outside her nest. *cf.* nipple-clinging.
- nocturnal:** pertaining to the night, or active during the night, when light intensity is at its lowest; between sunset and sunrise. *cf.* crepuscular (*q.v.*); diurnal (*q.v.*).
- nomadic movements:** irregular and unpredictable movements, from one locality to another, made by species living in unpredictable habitats. *cf.* localized movements (*q.v.*); migration (*q.v.*).
- nomen dubium:** when the available evidence is not sufficient to permit the identification of a species, its name is considered to be a *nomen dubium* and therefore not available for taxonomic purposes.
- nomen nudum:** a name that is not valid because, when it was originally published, the organism to which it referred was not adequately described, defined or sketched. The name is therefore invalid because it is impossible to associate it indisputably with any specific organism.
- nominate subspecies:** the subspecies that bears the name of the species to which it belongs, only brought into existence by the

- creation of one or more other subspecies in the same species. Subspecies are rarely used in rodent and lagomorph taxonomy at the present time.
- North Africa:** those parts of Mauritania, Morocco, Algeria, Tunisia, Libya and Egypt that are north of the Sahara Desert.
- north-central Africa:** southern Chad and southern Sudan, west of the Nile R. and south of the Sahara Desert. Mainly savanna habitats.
- North-West Africa:** (= the Mahgreb) those parts of Mauritania, Morocco, Algeria, Tunisia and NW Libya that are north of the Sahara Desert.
- nuchal patch:** patch of hair on back of neck, often contrasting in colour with that of the surrounding pelage (in lagomorphs). *See also* gular patch.
- nulliparous:** not having given birth.
- obligate:** obligatory; limited to one mode of life or action irrespective of conditions or circumstances. *cf.* facultative (*q.v.*).
- occipitonasal length:** the length from the most anterior margin of the nasal bones to the posterior part of the occiput. *cf.* greatest length of skull (*q.v.*).
- occiput:** the posterior part of the skull, above and lateral to the foramen magnum (*q.v.*).
- occlusal:** pertaining to the biting surface of a tooth.
- olecranon process:** large bony process at the proximal end of the ulna bone (forearm); very well developed in some subterranean mammals.
- Oligocene:** geological epoch (within the Tertiary period), ca. 23–38 mya.
- omnivore** (*adj.* **omnivorous**): an animal that eats a wide range of foods.
- opisthodont:** of the incisor teeth, directed posteriorly. *cf.* proodont (*q.v.*); orthodont (*q.v.*).
- orbit:** bony cavity (eye-socket) in which the eye is situated.
- orthodont:** of the incisor teeth, directed more or less in a vertical plane. *cf.* pro-odont (*q.v.*); opisthodont (*q.v.*).
- outer:** furthest from the mid-line of the body.
- ovulation:** the release of female gametes (ova, egg cells) from the ovary.
- ovum:** the female gamete or egg cell.
- owl pellets:** waste material, normally cylindrical with rounded ends, regurgitated by owls, which contains undigested fragments of bone, hair, feathers and scales etc. from the prey; for mammalogists, useful in determining indirectly the species of small mammals in a habitat.
- P or p:** (*abbrev.*) premolar tooth; upper case denotes adult dentition, lower case denotes deciduous dentition (milk teeth). *See also* premolar.
- P⁴–M³:** (*abbrev.*) measurement of the length of the four cheekteeth (fourth premolar to third molar) in Sciuridae etc. *cf.* M¹–M³.
- Palaearctic:** a zoogeographic region comprising temperate Europe, North Africa and the Arabian peninsula.
- Palaeocene:** geological epoch (within the Tertiary period), 55–65 mya.
- palatal ridges:** a series of ridges on the roof of the mouth (soft palate) arranged transversely; not visible on bony palate of skull. The number and arrangement of ridges are useful diagnostically in some genera of murids.
- palate:** the roof of the mouth. The anterior part (hard palate) comprises the bony palate (*q.v.*, formed by the premaxillae, maxillae and palatine bones), and a covering mucous membrane. The soft palate (covering the bony palate and extending posteriorly) is composed only of muscular tissue covered by a mucous membrane. *See also* bony palate.
- palpably pregnant:** describes a pregnant female whose pregnancy has been detected only by feeling the foetus(es), not by dissection. It is not possible to detect the early stages of pregnancy by palpation.
- papilla** (*pl.* **papillae**): a small projection or protuberance.
- paracone:** in rodents, the cusp (t6) located on the labial side of the central lamina of an upper molar tooth.
- paraconid:** principal cusp located at the anterior lingual side of lower molars in basal groups related to rodents; absent in Rodentia proper and believed to be a synapomorphy for the Order.
- paraoccipital process:** narrow strut-like bone, which projects ventrally from the paraoccipital bone on the posterior part of the skull.
- parapatry** (*adj.* **parapatric**): the situation where two or more species have geographic ranges that are contiguous but do not overlap. This abutting may be along a line of habitat discontinuity, an ecotone, or an altitudinal/climatic contour, but may also arise from competitive exclusion of one (or both) by the other.
- paraphyletic:** describes a taxon containing units that have evolved from a single ancestral taxon but which do not contain all of the descendants of the most recent common ancestor.
- paratype:** a specimen collected at the same time and place as the holotype (*q.v.*) and designated by the original authority as such. There may be one or more paratypes.
- parietal:** one of the pair of bones forming the vault of the braincase, situated between the frontal and the occipital bones.
- parous:** having given birth.
- partim:** in taxonomy, used in context of taxon names and synonyms to indicate that not all material that has been referred to the name is currently considered to belong to that name.
- parturition:** the act of giving birth.
- patagium** (*pl.* **patagia**): membranous flap of skin stretching between forelimb and hindlimb, and between hindlimb and tail; when stretched, forms an aerofoil that facilitates gliding (non-flapping flight) from tree to tree in some taxa of rodents. The same term is used for the flight membranes in bats.
- pectoral:** pertaining to or situated on the chest.
- pelage:** the hairy, woolly or furry covering of the body in mammals. The pelage variously consists of hairs, guard hairs and underfur according to the species.
- pencil:** hairs on terminal end of tail, which form a small slight tuft; hairs usually rather short (5–10 mm); hairs may extend beyond the end of the bony tail (e.g. *Gerbillus*, *Tatera*, *Taterillus*, *Grammomys*).
- phalanx** (*pl.* **phalanges**): one of the bones in a finger.
- phenotype:** the visible characters of an individual resulting from the interaction between the genotype (*q.v.*) and the environment.
- philopatry:** the tendency to remain in, or consistently return to, the place where one was born.
- philtrum:** the groove present in some mammals on the median line of the upper lip.
- phylogeny** (*adj.* **phylogenetic**): the evolutionary history and line of descent of a species or higher taxonomic unit.

- phytophilic**: living or thriving with plants; inhabiting domiciles in foliage, on tree trunks, in hollow trees, under bark etc. *cf.* anthropophilic (*q.v.*); lithophilic (*q.v.*).
- piloerection**: the erection of hairs, which occurs as a means of conserving heat (*see* temperature regulation) and, in some mammals, as a threat display.
- pinna** (*pl.* **pinnae**): the external (outer) ear.
- placental scar**: a scar on the inner surface of the uterus of a mammal indicating the site where a placenta was attached during pregnancy. If the average number of young/litter is known, the number of placental scars can give an indication of the number of litters that a female has had during her life-time.
- planar**: the condition in which the occlusal surface of the cheekteeth in rodents is flat, lying in one plane; a specialization usually found in species with high-crowned teeth whose chewing motion is primarily propalinal.
- plantar**: of the sole of the foot.
- Pleistocene**: geological epoch (within the Quaternary period), ca. 10,000 to 1.7 million years ago.
- plesiomorphy** (*adj.* **plesiomorphic**): having a similar form; a character state shared by different groups of biological organisms and inherited from a common ancestor. *cf.* apomorphy (*q.v.*).
- Pliocene**: geological epoch (within the Tertiary period), ca. 2–5 mya.
- poikilothermic**: describes animals whose resting body temperature is the same as, or within 1–2 degrees of, the ambient temperature.
- pollex**: Digit 1 ('thumb') of forefoot ('hand').
- polymorphism** (*adj.* **polymorphic**): the existence, within a species or population, of individuals having different forms (colour, size, shape etc.).
- polyoestrous**: having two or more litters/year. For species and/or populations that are described as polyoestrous, each female has two or more litters/year. *cf.* monoestrous (*q.v.*).
- polyphyletic**: describes a taxon derived from two or more ancestral sources; not of a single, immediate line of descent (Mayr *et al.* 1953). *cf.* monophyletic (*q.v.*).
- polyphyly**: derivation of a taxon from two or more ancestral sources. *cf.* monophyly (*q.v.*).
- polytocous**: normally or often having more than one young per litter. *cf.* monotocous (*q.v.*).
- polytypy** (*adj.* **polytypic**): a taxon that has several taxa in the next lower taxonomic category, e.g. a polytypic family contains two or more genera, a polytypic genus has two or more species, a polytypic species has two or more subspecies. *cf.* monotypy (*q.v.*).
- postauricular**: behind the external ear (pinna).
- posterior palatal foramen** (*pl.* **foramina**): foramen (*q.v.*) (often inconspicuous) in the palatine bone on the ventral surface of the skull situated in rodents between the cheekteeth; foramina are always in pairs and elongated in an anterior–posterior direction. *cf.* anterior palatal foramen (*q.v.*).
- posteroloph**: transverse enamel ridge that forms part of the posterior cingulum, defining the posterior rim of the upper molar teeth.
- postorbital**: behind (posterior to) the orbit.
- postorbital process**: a process that projects laterally from the parietal bone above the orbit; well developed in some species of squirrels.
- postpartum oestrus**: an oestrus cycle immediately after (or very soon after) parturition and while lactating. *See* Vol. 4.
- precocial**: describes young in which fur covers the body, eyes and ears are open, and adult-like movements are possible immediately or very soon after birth. *cf.* altricial.
- pregnancy rate**: the proportion of adult females in a population which are pregnant at any one time; usually expressed as a percentage of the total number of adult females.
- premaxilla**: one of a pair of bones at the anterior end of the skull, which bears the incisor teeth.
- premolar**: tooth or teeth on the maxilla bone situated immediately anterior to the molar teeth; usually preceded in time by deciduous (milk) teeth; multi-cusped. Structure and function of premolar teeth vary according to species and are diagnostic for a taxon. In many taxa of rodents, premolar teeth are not present; in others, only P⁴ is present. *See also* dental formula.
- preorbital**: anterior to the eye.
- prismatic**: high crowned molar tooth of rodents in which conical cusp definition is lost and the flat occlusal surface appears as interlacing triangular-shaped prisms.
- promiscuity**: a mating system in which each male mates with several females and each female mates with several males.
- pro-odont**: of the incisor teeth, directed anteriorly. *cf.* orthodont (*q.v.*); opisthodont (*q.v.*).
- propalinal**: chewing motion in certain rodents, typically associated with the evolution of high-crowned molars, in which the prevalent movement of the mandible is anterior–posterior (as in species of Arvicolinae).
- protocone**: in rodents, the cusp (t5) located centrally in the middle lamina of an upper molar tooth.
- protoconulid**: small accessory cusp found in certain species of gerbilline rodents, situated between the protoconid and anteroconid and assimilated with the latter after a little wear. Presence of protoconulid is considered as a primitive trait.
- proximal**: nearest to the body or to the mid-line of the body; nearest to the point of attachment. *cf.* distal (*q.v.*).
- pterygoid**: one of a pair of cranial bones forming part of the roof of the mouth.
- Quaternary**: geological period, present time to ca. 2 mya, comprising two epochs: Pleistocene (*q.v.*) and Holocene (Recent) (*q.v.*).
- R.**: (*abbrev.*) River.
- ramus**: one half (left or right) of the lower jaw or mandible.
- range length**: distance between the most distant captures (by live-trapping) of an individual; a rough method of assessing home-range (*q.v.*).
- relatively**: used in the context of describing the size of one character relative to the size of a different character in the same individual. Usually expressed as a percentage. e.g. Tail 80–90% of HB. *cf.* comparatively (*q.v.*).
- relict forest**: a forest that persists where local conditions are favourable after the disappearance of forest from the surrounding area as a result of climate change or human activity. Relict forests include those at the base of inselbergs that are watered by rainwater running off the inselberg, and forests growing in graveyards and sacred sites that are protected. Sometimes known as forest islands.

- relict population:** one that persists where local conditions are favourable after the extinction of the species from at least part of its former range.
- reproductive capacity:** number of young produced by a female during the breeding season.
- reproductive chronology:** the timing and duration of events, such as spermatogenesis, copulation, ovulation, gestation, parturition, lactation and reproductive inactivity, throughout the year.
- ridge:** in teeth, a ridge connecting two cusps. Also called commissure.
- Rift Valley:** deep valley extending from the Red Sea through Ethiopia and East Africa to Malawi; formed ca. 12 mya by subsidence of the valley floor and uplifting of the edges to form mountains and highlands. Comprised of four parts: (1) Ethiopian Rift Valley dividing the Ethiopian plateau into two parts; (2) Albertine Rift Valley (Western Rift Valley) in Uganda, E DR Congo and W Tanzania; (3) Gregorian Rift Valley (Eastern Rift Valley) in N Kenya, C Kenya and N Tanzania; (4) Malawian Rift Valley – the extension of the Albertine Rift Valley in Malawi. The Rift Valleys are noted for their many deep and beautiful lakes.
- riverine forest:** forest growing along the banks of a river or stream where conditions are moister than in the surrounding area. Sometimes referred to as ‘fringing forest’.
- Robertsonian fusion:** a chromosomal event involving the apparent fusion of non-homologous single-armed (telocentric *q.v.*) chromosomes to form a bi-armed (metacentric *q.v.* or submetacentric *q.v.*) chromosome. Modern studies have revealed that all chromosomes have two arms, even if the smaller one is not detectable by light microscopy. Consequently, the term Robertsonian translocation is becoming more commonly used than Robertsonian fusion.
- rostral:** pertaining to the rostrum.
- rostrum:** that portion of the skull anterior to the front line of the orbits and supporting the upper part of the muzzle, comprised of the nasals, premaxillae and maxillae bones.
- rupicolous:** rock-living.
- s.u.:** (*abbrev.*) (*Lat. sans unguis* = without claw) sometimes added as a suffix to the hindfoot measurement to emphasize that HF has been measured without the claw. However, since this is the standard method of measurement for rodents and lagomorphs (that often have broken or worn claws), most authors write ‘HF’, not ‘HF s.u.’. *cf.* c.u. (*q.v.*).
- sagittal crest:** longitudinal crest of raised bone on the mid-dorsal line of the cranium.
- saltatorial:** jumping on the two hindlimbs, as in jerboas and springhares.
- sand-bathing:** a method of cleaning the pelage by lying in the sand; during sand-bathing, the body is wriggled and the limbs kick and throw sand over the body. Observed in many species of desert rodents.
- scansorial:** climbs or scrambles over logs and in low vegetation close to the ground. *cf.* terrestrial (*q.v.*); arboreal (*q.v.*).
- sclerophyllous:** describes vegetation having hard leaves that are resistant to drought.
- scrotal:** pertaining to, or within, the scrotum (*q.v.*).
- scrotum:** an external sac containing the testes and epididymides in male mammals.
- scuttling:** rapid cursorial locomotion over the ground (or similar surfaces) in which the limbs move quickly; for rats and other small mammals, scuttling is quadrupedal.
- Senegambia:** Senegal and Gambia.
- sensu lato:** (*Lat.*) in a broad sense.
- sensu stricto:** (*Lat.*) in a strict sense.
- septum:** a dividing wall separating two cavities.
- sex ratio:** the number of males to the number of females, usually expressed as a proportion to one male, e.g. 1 : 1 (equal numbers of males and females), 1 : 0.5 (= twice as many males as females), 1 : 2 (= twice as many females as males).
- sexual dimorphism:** observable (phenotypic) difference(s) (e.g. in colour, size or form) between the males and females of a species or higher taxon.
- sibling species:** true species that are reproductively isolated and do not interbreed but are difficult to separate solely on basis of morphological characters.
- side-stripe:** longitudinal stripe(s) of contrasting colour on each flank, usually from shoulder to rump or upper part of hindlimb. Number of side-stripes on each flank varies from one (as in some squirrels) to about four (as in some species of *Lemniscomys*). Most side-stripes are continuous, but in some species of *Lemniscomys* some side-stripes are broken into spots and streaks.
- singleton:** a neonate born singly as opposed to being one of a larger litter.
- sister species:** species thought to have arisen from a single dichotomous splitting event.
- south-central Africa:** Angola, SE DR Congo, Zambia and Malawi (but only west of L. Malawi and the Shire R. Valley).
- southern Africa:** south of the Cunene and Zambezi Rivers, i.e. Namibia, Botswana, Zimbabwe, southern Mozambique and South Africa (after Smithers 1983).
- sperm:** any male gamete; the male cell that fuses with a female gamete (ovum, egg cell) to produce a fertilized egg or zygote from which an embryo will develop.
- spermatogenesis:** the formation of sperm in the testes.
- sub, sub-:** prefix meaning under, signifying beneath or ventral to (as in anatomical features) or south of (as in sub-Saharan); less than (as in subsonic); not quite, nearly, almost, somewhat (as in subequal, subtriangular). In taxonomy, indicates a group just below the status of the taxa immediately following it (e.g. a genus may contain two or more subgenera).
- subauricular:** below the ear.
- subcaudal:** below the tail.
- submetacentric:** describes a chromosome with the centromere somewhat nearer one end than the other, so there are two arms of somewhat unequal length (ratio 1 : 1.2–1.9). *cf.* metacentric (*q.v.*); subtelocentric (*q.v.*).
- subspecies:** a geographically localized and isolated subdivision of a species, which differs genetically, morphologically and taxonomically from other subdivisions of the species.
- subtelocentric:** describes a chromosome with the centromere much nearer one end than the other, so there are two arms of very unequal length (ratio 1 : >2).
- subterminal:** just below the end or tip.
- subterranean:** living permanently below the ground; subterranean mammals show many adaptations for life underground, e.g. short

- limbs, thickset shoulder blades and forelimbs, reduced eyes, reduced ability to see, reduction (or absence) of ear pinnae, large extra-buccal incisors, sensory hairs over all the body, feet fringed with hairs, extensive subterranean burrows, etc. (e.g. species of Bathyergidae and Spalacidae). *cf.* fossorial (*q.v.*).
- suckling:** the act of a mother giving milk directly from her breast (mammary glands) to her young. Mothers suckle; their young suck.
- supraorbital:** above (dorsal to) the orbit.
- supraoccipital crest:** crest or ridge of bone, oriented transversely across the back of the skull, at the junction of the parietal and/or supraoccipital bones and the occipital bone. Sometimes referred to as the lambdoid crest.
- supraorbital process:** bony process on outer edge of frontal bone extending outwards above the orbit in lagomorphs.
- supraorbital ridge:** ridge of bone along upper rim of orbit (eye-socket); can be well developed, low or absent.
- sympatry** (*adj.* **sympatric**): the situation where populations of two or more different species have overlapping geographic ranges; refers also to populations of two or more species whose geographic ranges are partly or wholly overlapping. They may or may not interact. *cf.* allopatry (*q.v.*); syntopy (*q.v.*).
- symplesiomorphy:** a primitive or ancestral character shared by two or more groups, which is inherited from ancestors older than the last common ancestor.
- synanthropic:** associated with humans and/or their houses and other buildings.
- synapomorphy** (*adj.* **synapomorphic**): situation in which a homologous character is present in two or more taxa and is thought to have originated in their most recent common ancestor. *See also* apomorphy.
- synonym:** one or more of different names for the same taxonomic unit. A synonym may be a 'senior synonym' (the oldest name), or a 'junior synonym' (a more recent name), which is no longer considered to be valid. May be used to refer to all names that have been associated, at some time in the past, with the taxonomic unit as currently understood.
- syntopy** (*adj.* **syntopic**): describes the situation where two or more species use the same or similar habitats and activity times. They may or may not interact. *cf.* allopatry (*q.v.*); sympatry (*q.v.*).
- syntype:** any specimen, or one of a series of specimens, used to designate a species when a holotype (*q.v.*) and paratype(s) (*q.v.*) have either not been selected, or have been lost or destroyed.
- systematics:** the science of arranging organisms in a way that reflects their evolutionary relationships; such relationships may be expressed as a phylogeny (*q.v.*). Often defined (somewhat incorrectly) as a synonym of taxonomy (*q.v.*).
- t:** (*abbrev.*) (= tubercle) as used to describe and number the cusps on premolar and molar teeth, e.g. t1, t3, t5. The presence/absence, position and size of longitudinal ridges between cusps are diagnostic for many taxa of rodents.
- T:** (*abbrev.*) length of tail, measured from the anterior end of the first caudal vertebra to the posterior end of the last caudal vertebra (excluding any tufts, bristles etc. at tip of tail).
- T_a:** (*abbrev.*) ambient temperature; the temperature in which an animal is living. *cf.* T_b (*q.v.*).
- taloid:** heel at the posterior end of a lower molar tooth.
- tapetum lucidum:** light-reflecting layer in the retina of the eyes of some vertebrates.
- taxon** (*pl.* **taxa**): any defined unit (e.g. family, genus, species, subspecies) in the classification of organisms.
- taxonomy:** the science of biological nomenclature; the study of the rules, principles and practice of naming and classifying species and other taxa. Sometimes considered as an integral part (and near synonym) of systematics (*q.v.*).
- T_b:** body temperature; the temperature of the core (central) part of an animal. *cf.* T_a (*q.v.*).
- telocentric:** describes a chromosome that appears to have a terminal centromere and therefore only one arm. Modern studies have revealed that all chromosomes have two arms but the smaller arm of telocentric chromosomes is not visible under a light microscope.
- termitarium** (*pl.* **termitaria**): a place where termites (Insecta: Isopoda) live. Often a large mound of modified hard soil. The shape and size of a termitarium is unique to each species of termite.
- terrestrial:** living on the ground. *cf.* arboreal (*q.v.*); scansorial (*q.v.*).
- territory:** an area defended by an individual against certain other members of the species, usually by overt aggression or advertisement; territory is marked by the urine, faeces or glandular secretions of the territory's owner. *cf.* home-range. The boundary of a territory is a line across which the status of the territory holder changes from dominant to subordinate.
- Tertiary:** geological period, 2–65 mya, comprising five epochs: Palaeocene, Eocene, Oligocene, Miocene and Pliocene (*q.v.*); followed by the Quaternary period (*q.v.*).
- testes:** the male gonads, or testicles, in which spermatozoa are formed and in which the male hormone is produced.
- thermoneutral zone:** the range of body temperatures within which an animal does not have to increase its metabolic rate to increase T_b (*q.v.*) (when T_a (*q.v.*) is low) and reduce T_b (when T_a is high).
- thermoregulation:** regulation of body temperature, either by metabolic or behavioural means (or both simultaneously) so that T_b (*q.v.*) is kept more or less constant.
- thoracic:** pertaining to, or situated upon, the chest.
- TL:** (*abbrev.*) total length from tip of snout to posterior end of tail. Equivalent to the head and body length and tail length added together. *See also* HB and T.
- toothrow:** the teeth situated posterior to the diastema in rodents and lagomorphs (and some other orders of herbivorous mammals). The upper and lower tooththrows are comprised of premolar and molar teeth, or only molar teeth. Although small cusps are present on the surface of each tooth in a tooththrow in young animals, these cusps wear with age to form a smooth grinding surface; the pattern of enamel and dentine of the grinding surface may be used to assess the age of the individual. A tooththrow may contain three teeth (all molars, e.g. most murid rodents), four teeth (one premolar, three molars, e.g. some squirrels, porcupines, springhares), five teeth (two premolar, three molars, e.g. some squirrels) or six teeth (three premolars, three molars, e.g. lagomorphs).

- topotype**: any specimen from the type locality (*q.v.*), i.e. the same locality as that from which the holotype (*q.v.*) was taken.
- topotypical**: pertaining to the type locality (e.g. a topotypical population is one found at the type locality).
- torpor** (*adj.* **torpid**): a state in which there is reduction of metabolic rate and a lowering of T_b (*q.v.*) when T_a (*q.v.*) declines; arousal from torpor occurs when T_a increases and without high energy costs to the individual. Torpor is associated with a state of inactivity and reduced responsiveness to stimuli. Torpor lasts for only short periods of time (hours or days) (*cf.* hibernation).
- transverse**: in a direction across the body from side to side. *cf.* longitudinal (*q.v.*).
- tricuspid**: having three points or cusps (particularly of teeth).
- tubercle**: a small rounded protuberance, e.g. a cusp of a tooth.
- tympanic bulla** (*pl.* **tympanic bullae**): one of a pair of usually rounded bony capsules, on underside of skull (one on each side), housing structures of the middle and inner ear in many mammals. Also called auditory bulla (*q.v.*).
- type description**: the original description of a species; the original description of the holotype (and paratype[s] if included).
- type locality**: the locality from which a holotype (*q.v.*), lectotype or neotype was collected. Also called topotypical locality.
- type series**: the holotype and all specimens collected at the same place and time and used, together with the holotype, to describe a new species.
- type species**: usually the species that was the first to be described under the name of a new genus. Not all genera had a designated type species when they were first created; in such cases, other rules determine which species will be the type species.
- type specimen**: *see* holotype.
- underfur**: dense and often woolly layer of the pelage, situated close to the skin and below the soft hairs and guard hairs; usually short and present in those species that experience lower T_a .
- unicuspid**: having one cusp or point (particularly of teeth).
- vagrant**: an individual that has been found well outside the normal geographic range of its species, e.g. a bat or bird that has been wind-borne, or an animal that has been transported as a stowaway on a ship, to a distant locality.
- vascularized**: infiltrated with capillaries.
- vasoconstriction**: constriction of the capillaries of the blood system near the surface of the skin in order to reduce the rate of heat loss through the skin; a mechanism used by many mammals to conserve heat when T_a (*q.v.*) is low. *cf.* vasodilation (*q.v.*).
- vasodilation**: the dilation (or opening) of the capillaries of the blood system near the surface of the skin in order to increase the rate of heat loss through the skin; a mechanism used by many mammals to cool themselves when T_a (*q.v.*) is high. *cf.* vasoconstriction (*q.v.*).
- veld**: Afrikaans word, used mainly by southern African biologists, to refer to a wide variety of grassland vegetation types typically used for grazing. *See also* bushveld, highveld, lowveld.
- vertebra** (*pl.* **vertebrae**): any of the bones that make up the backbone.
- vibrissa** (*pl.* **vibrissae**): long stiff hairs on the face, especially around nostrils and lips; often associated with the perception of tactile sensation; 'whiskers'.
- vlei**: southern African term for a marsh or swamp, either permanent or seasonal.
- wadi**: a desert valley, usually dry at the surface except after heavy rainfall.
- water turnover**: the rate at which water (fluids) is utilized and replaced in the body per unit time (normally expressed as ml/kg body weight/day); the amount of water an animal processes through its body each day. Water turnover is related to water availability, the urine concentrating ability of the kidney, amount of protein in the diet and T_a (*q.v.*). Water turnover rates are characteristically low in arid-adapted mammals when compared with non arid-adapted mammals.
- West Africa**: ca. south of 18°N from Senegal to the Sanaga R. in Cameroon, and Bioko I. (Equatorial Guinea) (Rosevear 1965).
- Wurch**: Ethiopian word for the alpine agricultural/economic altitudinal zone, above about 3000 m, too cold for most agriculture.
- Woina Dega**: Ethiopian word for the warm-temperate agricultural/economic altitudinal zone, about 1500–2300 m, warm enough for most agriculture.
- WT**: (*abbrev.*) weight of an individual, usually expressed in grams (g) or kilograms (kg).
- ZW**: (*abbrev.*) *see* zygomatic width.
- zygomatic arch**: one of a pair of cheekbones, formed of the maxillary process anteriorly, jugal bone medially and squamosal bone posteriorly. Ranges from massive, broad, widely flared and bony, to frail, slender and cartilaginous. When present provides protection to the eyes and orbits. Also called zygoma.
- zygomatic plate**: expanded and flattened lower part of the maxillary process on the outer side of the infraorbital foramen (*q.v.*); variations in size and shape are useful for identification of some rodents.
- zygomatic width (ZW)**: greatest width between the outer aspect of one zygomatic arch to the equivalent position on the opposite zygomatic arch. *See also* GWS.
